Although the principles of inertial guidance are decades old it is only recently that application of new technology has resulted in measurements of much smaller angles and accelerations. This makes the modern stabilized gyro system an important navigating device for military aircraft and the heart of a long range ballistic missile. As Dr. Draper pointed out: "It is not the system but the state of the art which is news."

The Instrumentation Laboratory is under MIT's Division of Sponsored Research. The Staff currently employs more than 700 working in laboratories in Cambridge and at a Flight Facility at nearby Bedford, Mass.

50-Ton Machine Tool Guided by Tape

Details of the first production application of a punched-tape control system to a huge machine tool, using electronics to process blueprint information and turn out precision-built structural parts, have been revealed by the Martin Co. and Bendix Aviation Corp. The new system will be used in aircraft and missile manufacture at Martin's Baltimore division.

Built to Martin specifications by the Research Laboratories division of Bendix, the new system is a 50-ton, three-dimension (engineers call it three-axis) milling machine with associated electronic equipment that eliminates the need for hand-made patterns or master parts which themselves normally require several hundred man-hours to produce.

Dr. Albert C. Hall, general manager of the Bendix Research Laboratories division, explained that the tape-controlled process, technically known as "numerically controlled milling," was first used in mass production by Bendix to solve a bottleneck in the manufacture of a small, intricate cam that is one of the key parts of a jet engine fuel-metering system. In this instance, production of a "master cam" was a one-man job requiring from 5 to 10 weeks of highly skilled work. With the tape-control process, that operation can be completed in from two to four days.

New Electronics Firm is Organized

A new corporation, Era Engineering, Inc., has recently been formed by a group of scientists and engineers with aircraft and missiles industry experience. The company says its objective will be the development of new systems and devices in the fields of electronics, radiation and rocketry. Office facilities and laboratories have been located in Santa Monica, Calif.

The group, headed by Mr. David Shonerd, announces three new systems now available: (1) A simple system for measuring the distance between a missile and its target in a "near-miss" situation; the system will assess the effectiveness of missiles under experimental firing conditions and information will be available to firing crews immediately after impact, (2) a device for measuring the erosion of materials on missile surfaces under hypersonic environments; also available will be a complete system for measuring and recording the thickness of a skin material as a function of time, and (3) a radioactive recovery technique to mark and insure recovery of missiles and missile components after experimental flight.

ARDC Sponsors "Smoke Puff"

Operation Smoke-Puff will begin in July this year at ARDC's Holloman Air Development Center. An extension of earlier tests, Smoke-Puff will constitute a detailed analysis of the effects of a man-made electron or ion cloud upon high-frequency radio signals.

No ordinary **Dynamicist** will do for this job...

The engineer we need has superior creative ability and an analytical mind. He now has senior status—a Mechanical, Chemical, Electrical Engineer or Engineering Physicist (preferably with advanced degree) who is versed in classical vibration analysis, as well as feedback analysis for control of systems composed of Heat Transfer, Fluid Mechanics and Thermodynamic processes.

Dynamical system of the High-Thrust Liquid Propellant Rocket Engine is one of extraordinary interest, exceptional performance. No matter what your achievements have been, you'll find new interests at Rocketdyne. You will be confronted with the analysis of design and operational problems of the rocket engine as a dynamic system. You must develop valid mathematical models of both systems and components, using advanced physical concepts and empirical data. These must be combined using digital computation and analog simulation.

You'll work with the leading producer in the nation's fastest growing industry. Rocketdyne builds the high-thrust rocket propulsion systems for America's major missiles.

We know we can show you, in a personal discussion, all the opportunity you could wish for. Write to: Mr. A. W. Jamieson, Rocketdyne Engineering Personnel Dept. MAR-5, 6633 Canoga Avenue, Canoga Park, California.

BUILDERS OF POWER FOR OUTER SPACE

time tested shock mount

The critical moving coil in Weston ruggedized instruments is insured against shock damage by these shock absorbing springs in back of each jewel bearing . . . another Weston ruggedized *first!*

The entire instrument movement is then cradled on a shock mount of specially formulated rubber . . . assuring continuous dependable operation in severest service.

WESTON

Ruggedized

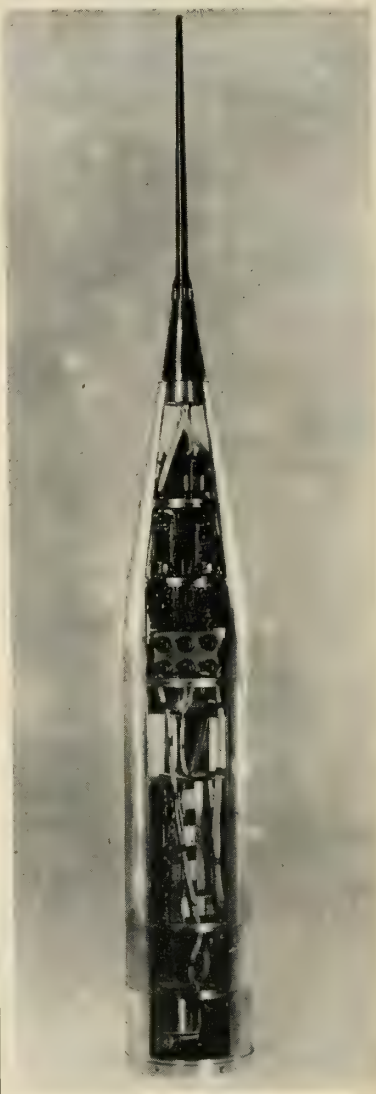
PANEL INSTRUMENTS

A DAYSTROM UNIT

Equipment builders can't afford to compromise on instrumentation where service requirements call for instruments that will function dependably under severe impact, shock, moisture or temperature extremes. That's why *approved* Weston ruggedized instruments are so widely preferred. Their sound basic design . . . the *extra* values built-in . . . have proved their superiority under the most rigorous field conditions, providing unmatched performance that more than justifies their cost.

Expanded facilities now make Weston ruggedized instruments readily available for A-C or D-C needs in a variety of sizes and ranges. For the complete story, consult your local Weston representatives, or write . . . WESTON Electrical Instrument Corp., Newark 12, N. J.

French *Monica* Rocket Performs Well at Low Cost



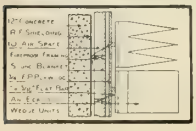
Designated the *Monica*, the French A.T.E.F.-14 series of three-stage sounding rockets have been undergoing development for more than two years. Utilizing a solid propellant, designated "plastolite," these rockets are notable for high performance, simplicity and low cost. Payloads of up to 33 lbs. have been carried to altitudes of over 300,000 ft.; 17 lbs. to nearly 500,000 ft. The cost per unit is 500,000 Francs (about $1,400). These facts indicate that French development of the art of low cost sounding rockets compares favorably with current U.S. work.

Four Models of *Monica* have been built to date. Characteristics and performance are detailed in the Table shown. In each of the first three models, two designs were tried, Type A in each case carrying double the payload of Type B. *Monicas* have a diameter of 6¼". Lengths vary from 10 ft. to nearly 18 ft.

Construction is relatively simple. The rocket body is of dural about ¼ in. thick. The rocket motor is of steel with a graphite nozzle. The individual stages are mounted in a slip-joint fashion.

The design thrust of the first stage is sufficient to take off from the launching ramp and achieve a velocity above Mach 1 in less than 5 seconds. Ignition of second and third stages is governed by time-delay relays designed to obtain maximum altitude. The rockets are shipped with propellant loaded. Ignitors and upper-stage firing relays are installed just prior to launch. Firing circuit runs on 12v. battery.

Monica's normal payload consists of instrumentation such as accelerometer, aneroid capsule, pirani gauge, and/or cosmic ray measuring devices. Telemetering is accomplished on AM-FM bands of 4-6 channels. Other research programs contemplated or underway include experiments with animals (recovering by parachute), temperature probes and release of chemicals in the ionosphere to study the resultant reactions. Firings have also been made with "window" to study the nature of winds and tracers to measure trajectories accurately.



MONICA instrumentation.

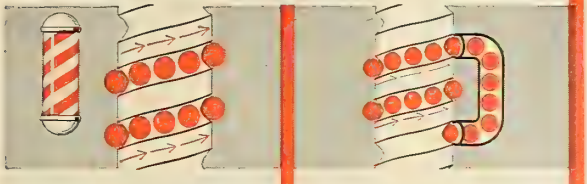
ACTUATION PROBLEM too tough for ordinary devices?



SAGINAW CAN HELP YOU SOLVE IT!

Saginaw b/b Screws guaranteed 90% efficient —offer 6 major advantages for designers

Available in custom machined and commercial rolled thread types—have been built from 1½ inches to 39½ feet long—⅜ to 10 inches diameter.

Nut *glides* on steel balls. Like stripes on a barber pole, the balls travel toward end of nut through spiral "tunnel" formed by concave threads in both screw and mating nut.

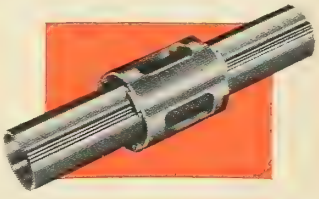
At end of trip, one or more tubular guides lead balls diagonally back across outside of nut to starting point, forming closed circuit through which balls recirculate.

1 VITAL POWER SAVINGS. With guaranteed efficiency of 90%, Saginaw b/b Screws are up to 5 times as efficient as Acme screws, require only ⅕ as much torque. This permits much smaller motors with far less drain on the electrical system. Circuitry is greatly simplified.

2 SPACE/WEIGHT REDUCTION. Saginaw b/b Screws permit use of smaller motors and gear boxes; eliminate pumps, accumulators and piping required by hydraulics. In addition, Saginaw b/b Screws themselves are smaller and lighter. Units have been engineered from 1½ in. to 39½ ft. in length.

3 PRECISE POSITIONING. Machine-ground Saginaw b/b Screws offer a great advantage over hydraulics or pneumatics because a component can be positioned at a predetermined point with precision. Tolerances on position are held within .0006 in./ft. of travel.

4 TEMPERATURE TOLERANCE. Normal operating range is from −75° to +275° F., but assemblies have been designed in selected materials which function efficiently as high as +900° F. These units are practical where hydraulic fluids have lost efficiency or reached their flash point.



5 LUBRICATION LATITUDE. Even if lubrication fails or cannot originally be provided because of extreme temperatures or other problems, Saginaw b/b Screws will still operate with remarkable efficiency. Saginaw units have been designed, built and qualified for operation without any lubrication.

6 FAIL-SAFE PERFORMANCE. Far less vulnerable than hydraulics. In addition, Saginaw offers three significant advantages over other makes: (1) Gothic arch grooves eliminate dirt sensitivity, increase ball life; (2) yoke deflectors and (3) multiple circuits provide added assurance against operating failure.

YOUR FREE COPY OF THIS NEW b/b SCREW AND SPLINE "PROBLEM SOLVER" SHOWS HOW

36 pages crammed with time-, work-, and money-saving facts: Principles • Types • Basic Operations • Coupling Methods • Efficiency • Advantages • Selection Factors • Design Data • Sample Problems

SAGINAW b/b SPLINE

● Averages 40 times lower coefficient of friction than ordinary sliding splines!

Utilizing the same basic *gliding ball* principle, Saginaw has developed the *Saginaw b/b Spline* which radically increases the efficiency of transmitting or restraining high torque loads.

It can be fitted with integral gears, clutch dogs, bearing and sprocket seats, etc. Units have been built from 3 inches to 10 feet long—⅜ to 6 inches in diameter.

ROCKET POWER PROGRESS REPORT

Taming Rocket Powerplants

by Walter O. Borcherdt

In charge of the Engineering Development Laboratory as well as the Valves and Controls Section at RMI, Mr. Borcherdt has over a decade of rocket experience. Before coming to RMI in 1951, he was senior project engineer on controls in the rocket department of Curtiss-Wright Corporation. Mr. Borcherdt received his degree in mechanical engineering from Stevens Institute of Technology in 1938.

Reliability of a rocket powerplant is the direct result of the simultaneously correct operation of all of its elements. Generally, this is assured by overcoming each element's own peculiar development problems. Among these elements is one type which has the interesting property of being composed of specific components, yet whose operational characteristics are significant only in the performance of the entire powerplant system. This element is the control system.

Present powerplant controls requirements are based on these straightforward, simple considerations:

1. **Prepare the powerplant for firing**
2. **Sequence and control the system to rated thrust**
3. **Vary thrust rapidly and safely as required**
4. **Shut down smoothly**

Step one may require the use of gas pressure regulators and relief valves to push the propellants safely from tankage to pumps. There must be switches and relays to indicate or control the valves which admit propellants to the gas generators and combustion chambers, and time delay cutouts to insure against unsafe accumulation of propellants.

In step two, ignition and combustion may be monitored to insure correct use of the high energy release rates. Turbines may be safely brought up to speed by throttling the propellants. Safety devices may be added to limit over-speed and avoid the danger of structural failure.

In step three, a controller (it may be hydraulic, electric, pneumatic, or a combination) is used to vary thrust. Here multiple loop servo systems are sometimes used to insure that thrust change rates, turbine speeds, vehicle acceleration or terminal velocity, and other parameters vary in a coordinated manner.

Finally, in multiple stage powerplants or piloted vehicles, the rocket engine must be shut down safely and the system automatically purged of propellant accumulations.

The successful implementation of these four steps involves the application of many devices of unique characteristics whose individual selection is intimately tied to the following question:

"What is the actual control system problem to be solved?"

Once this question is clearly and consistently defined, a tight performance envelope results. This makes the few possible solutions fairly obvious. The final stage is to apply the knowledge of a team of control specialists and proceed through the usual component development stages. At RMI, this team of specialists in controls engineering is made up of highly qualified mechanical, electrical and chemical engineers. These professional men have wide experience in the creation of control units and systems for rocket powerplants as well as other types of propulsion systems. However, there is a continuing need for qualified graduate engineers, able to participate in working closely with other groups of specialists, integrating the control system into the overall engine performance envelope.

The systems approach is of extreme importance to successful rocket powerplant control efforts. It is a standard approach of the RMI Controls Section. Sequence system design, switching circuit analysis, human engineering, feedback control methods, statistical procedures, information theory and latest research data on fluid flow control are among the techniques used. They are applied along with practical design concepts which result in the development of simple but effective controls systems.

If you desire one or more reprints of Mr. Borcherdt's article, or would like to receive further information about employment at RMI, write to our Information Services Coordinator. Reaction Motors, Inc., 16 Ford Road, Denville, New Jersey.

Power for Progress
RMI

Russians Backtrack On *Mouse* Origin

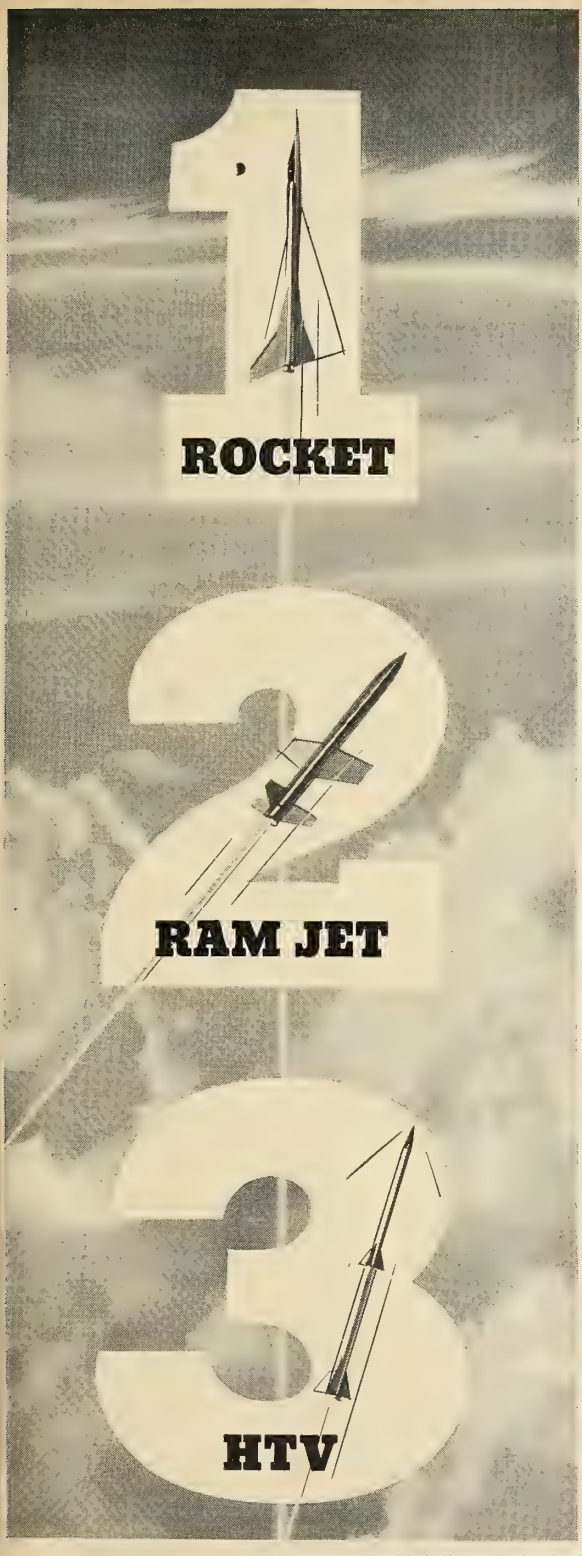
The Russians seem to have been embarrassed by m/r's disclosure last November that a Soviet magazine was guilty of satellite design plagiarism. They appear to be making amends. m/r pointed out that a cross-sectional schematic satellite drawing attributed to engineer B. Lyapunov and artist N. Antonov was an exact copy of one of Dr. S. Fred Singer's early *Mouse* versions. Now engineer Lyapunov has written a new two-page article on foreign rocket and earth satellite developments for the Russian magazine *Znanie-sila* (Knowledge Is Power). In it, Lyapunov uses virtually the same artificial satellite drawing that bore his name in the previous story. But this time he gives Dr. Singer full credit for the design both in the picture cutlines and in the article's text.

AF to Track Drones With Decca System

According to a report from an industry source, the Air Force is planning use of a Decca Navigator system to keep track of its target drones.

The drones would be equipped with Decca equipment to receive signals similar to those used in Great Britain for air and sea navigation.

Drones which "go over the hill" would transmit Decca coordinate information to search crews through telemetering equipment onboard. Exact location of the drone could be quickly determined.



Equipment would be supplied by the Bendix Pacific Div., Bendix Aviation Corp. which supplies Decca Navigator Co., Ltd. equipment in the U.S.

IRE Convention To Meet in June

A National Convention will be sponsored by the IRE Professional Group on Military Electronics in Washington, D.C. on June 17-19, 1957.

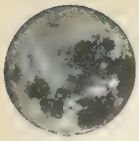
Admiral W. E. Cleaves, Bendix Radio Division, Bendix Aviation Corp. will chair the convention which will theme "Missiles and Electronics."

Appointed to the executive committee as staff advisors for the convention are assistant secretaries of defense Frank Newbury and C. C. Furnas.

CURTISS-WRIGHT

powerplants and missiles set new performance standards for tomorrow

A Curtiss-Wright Rocket Engine recently powered an aircraft higher and faster than man has ever flown before. A Curtiss-Wright supersonic Ram Jet Engine was the first controlled supersonic ram jet to be successfully flown – and advanced versions are now being developed for piloted aircraft and guided missiles. A Curtiss-Wright hypersonic test vehicle – the HTV Rocket – recently reached supersonic speed in a fraction of a second . . . developed several times the speed of sound in just two seconds.



These developments—all capable of several times the speed of sound – are the advanced guard in America's defense, and in America's research toward the high speed, high altitude air travel of tomorrow. They are dynamic evidence of Curtiss-Wright's leadership in the aviation industry – setting the pace for aviation's progress in *every* category of air power.

Missile Miscellany

This page is politically independent but skeptical . . . so it wonders:
——If it's to use up surplus funds that Post Office is investigating the possibilities of rocket mail service . . .
——If Defense Secretary Wilson, wandering about Patrick AFB and possibly holding his ears against Jupiter's roar, may have decided after all to learn something first-hand about missiles . . .
——How many realize how ineffectual true military security is; how effective Pentagon censorship has become; how it helps Uncle Joe's heirs and how it hurts Uncle Sam's . . .

The other night at a philosophical function, an ICBM propulsion engineer asked this page: "The missile's here to stay, but is man?" . . . and from an atom editor emeritus, a quip about Pentagon Security Review: "A certain type of cat gravitates to the job.'' . . . and a simple explanation of things complex by Commerce Undersecretary Louis S. Rothschild before House Appropriations Subcommittee: "In other words, the whole purpose of SAGE is to bring aircraft together, so that they can hit one another with ballistic missiles of one kind or another"—at last a mission for Jupiter? That same evening a Relativity novitiate wondered if anyone had ever stepped back and looked at the velocity-dependent approach of mass to infinity as a drag effect in an as yet undetected medium.

To prove that truth is stranger: Once upon a time an AF general telephoned m/r to ask: "What are you, an Army house organ?" And it came to pass within a fortnight it was heard from out the jungles of commerce this charge by an Army-contracted advertising prospect: "You're just an Air Force house organ!" After this issue of m/r, what?

Missile has now been defined as an "airplane which saves manpower by eliminating the pilot but takes 372 men to launch . . ." And a classified missile as "one which only a news magazine may print a picture of . . ."

The limiting problem in inertial guidance accuracy are the integration circuits (giving a series result) needed to transform inertially measured acceleration into velocity and then distance. One answer that works eliminates one integration step by using thrust control to fix velocity.

About faces—this page just heard about SAC Chief General Curtis LeMay's when first he saw movie of Sidewinder disappearing up jet tailpipe—also after he was assured it too could be given nervous breakdown . . . more on ECM reveals it's essential sometimes to drop the "E" and in same business to make sure nobody pushes wrong button and sucks attacker into target it's planned to take the fingers out of pushbutton warfare . . . still more on the unessentiality of man, a computer now watches other computers; reports every so often with complete psychoanalysis of its charges' troubles . . . then there's the early Bomarc test when condensation gave full nose down reading (that wasn't) and "corrective" control caused it to do two inside loops and whoomp smack alongside blockhouse . . . B-52's sometimes troublesome gun turrets are to be replaced with missile batteries . . . and talk too this page hears of radar invisibility . . . still serious, talk in high quarters of supersonic underwater flight—over 2700 mph . . . work at Aerojet on rocket torpedoes that top 140 knots—which may be related to Minneapolis-Honeywell guidance for "long-range" torpedoes and GE sonar detection gear good well over 100 miles . . . an expert says we know less about the ocean than we do surface of the moon . . . GE missileman sees rocket on moon with instruments and transmitter (look ma, no men! again) inside 20 years—whatsa delay! . . . if plankton dreams of oceanographers come true, to right is hydroduct fuel of the future . . .

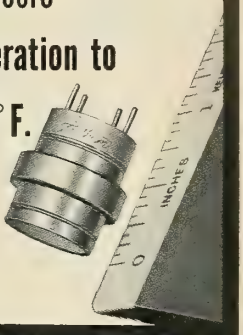
Rocket Trends

By Erik Bergaust

When we let our editors, correspondents and contributors loose on the subject of underwater warfare, submarine missiles and torpedoes, we learned one thing: the United States Navy is doing a tremendous job in this field—but industry is not at all aware of the fantastic possibilities that this field offers. True, many companies are working intensively on many sophisticated undersea warfare projects, but we found—nevertheless—that some of the most potential missile manufacturers did not even comprehend the concept of underwater missiles!

On the other side, we think it is appropriate to mention that many of the companies actively engaged in underwater missiles are so deeply involved in top secret work that the matter of covering their activities editorially was out of the question. But let us mention a few of them—without disclosing what they are doing—*Fairchild, General Electric, Convair Pomona, Raytheon, Coleman Enginering, Philco, General Mills, Minneapolis Honeywell, Brush Electronics, Clevite Research, Aerojet, Avco* and many others.

Yet, a good portion of what this country is doing in the field of underwater missile and submarine warfare is disclosed in the columns of this issue. As our publisher has pointed out in his editorial, this was made possible through the kind cooperation of Navy's Security Review Office. Perhaps we have only revealed a fraction of what's going on in this country—at any rate, let it be a warning to Russia's submarine commanders and their bosses in case they should be dreaming of a big surprise submerged mass attack on this country.



Our Navy is the number one marine defense force of the world. And in view of its meticulous efforts to advance itself in this field of silent, submerged warfare, and its awareness of the Red submarine threat, we can only invite industry to back our Navy in these efforts. It is crystal clear now that any Russian attack on this country will be a combination air-underwater assault. Her 500 to 600 submarines, eventually, would be used as missile launching platforms off our coasts. This is a rough threat—and a horrible thought—and we may not be prepared for this sort of thing. On the other hand, we have no reason to believe that Russia has perfected her entire submarine missile fleet and that she is ready for this kind of attack. And whenever she does get prepared we shall be equally capable to deter any such aggression.

The concept of undersea missiles is not new, but the application of such weapons is. Consequently, we have a long way to go. That's why industry must wake up right now and accept this important challenge. That's why inventors and designers must offer their ideas and suggestions now—so that our underwater early warning systems of the future and our anti-submarine weapons and missiles will be as supreme and deadly as our ballistic and anti-aircraft missiles.

We cannot tell now whether tomorrow's underwater super missiles will be propelled by solid rockets, electric motors, turbines, or what; we don't know whether they will be sonar-guided devices, or whether they will employ completely new guidance concepts. That's why there is room for a vast amount of research and development in this field, and that is why the goal of bringing about superior underwater missiles—whether they are designed to knock enemy planes out of the skies, or hit enemy subs or surface targets—should be pursued by every missile engineer.

This is the eighth issue of m/r. It is the second Navy issue. For good reasons. In fact, we now have published two Navy issues, two Air Force issues and one Army issue. Next? We have a vast field to cover. So we shall leave the services for a while and concentrate on the industry itself.

Miniature Pressure Transducers for operation to +400°F.

Temperature compensated over 465°F. interval

0.01% °F. thermal coefficient of sensitivity from −65° to +400°F.

0.01% FS/°F. thermal zero shift from −65° to +400°F.

No cement or resin pressure seals

Homogeneous sensing diaphragm surface

Statham unbonded strain gage transduction

Minimum response to vibration or acceleration

Pressure adapters for closed line applications

Absolute Pressure Transducers
0-5 to 0-500 psia—Model PA260TC

Gage Pressure Transducers
0-5 to 0-500 psig—Model PG260TC

Differential Pressure Transducers
0-5 to 0-500 psid—Model PL260TC
±2.5 to ±25 psid—Model PM260TC

When the transducer is a Statham, pressure measurements at elevated temperature are made with accuracy and confidence.

Washington Spotlight

By Henry T. Simmons

Flight test results for major new missiles are pouring into the Pentagon at a rapid clip as the tempo of firings picks up at Patrick AFB, Fla. The flood of data brings with it a new problem which may increasingly concern the military services and their civilian directors: how well does the tax-paying public and its press understand the basic philosophy of the missile flight test program? After hearing for many years the loud claims of the excellence of this or that service's weapons, it is not surprising if the public has become confused about the missile program, and even a little disgusted, as newspaper reports crop up headlining the explosion of a *Jupiter* or the failure of a *Thor*.

•

The purpose of a missile flight test program, in a nutshell, is to make the bird fail under informative conditions. Paradoxically, the missile which sticks to its flight plan is not providing information as valuable as the vehicle which blows up on its launching stand under circumstances which can be analyzed, duplicated and then obviated for all time. Keeping this in mind, it is easy to see that most of the recent firings at Patrick have been "successful" from a test standpoint, even though they would have been abject failures if they occurred on the battlefield.

•

The "big one" which Defense Secretary Charles Wilson saw fired at Patrick last month was the second flight test of the Army's *Jupiter* mid-range ballistic missile. The power lasted less than two minutes, with the bird apparently "failing" under circumstances similar to those in which its predecessor was lost earlier this year. One theory is that an eddy current formed by air blast at the skirt of the big missile drew rocket exhaust flame up around the base of the weapon and burned out some wiring.

•

A jittery range safety officer brought the second flight test of the Air Force's *Thor* mid-range ballistic missile to a sudden end in April. In a flight of about 40 seconds' duration, the big Douglas missile was sluggish in responding to its auto-pilot and appeared headed toward the mainland. Mindful of the time an Army *Redstone* fell on a nearby launching pad (thus becoming the world's first Inter-Pad Ballistic Missile), the safety officer detonated the *Thor* before it could do any damage.

•

North American's rocket-ramjet *Navaho* intercontinental missile also got a second test flight about mid-March, it was learned. Despite grave and almost comical difficulties, it succeeded in demonstrating two major features of its operation—booster separation and ramjet ignition. The big bird accidentally carried part of its launching apparatus away during firing. Air blast finally tore loose the unwanted super-cargo, but this caused the booster to lose thrust. Nevertheless, the booster engine separated as programmed and there is evidence of ramjet ignition before the XSM-64 test vehicle plunged into the sea.

•

Look for the Air Force to seek Defense Department authorization for a prototype development program for the WS-110 manned bomber sometime next fall. This is the successor to the B-52 which Boeing and North American are presently working on. The airmen won't succeed without a battle, however. One Pentagon official says privately he will object to a WS-110 hardware program until an engine is clearly in sight which can use high-energy fuel. There's also the matter of money. Military spending during the current fiscal year is likely to hit $38 billion—$2 billion more than the Administration predicted in January—and the Pentagon will be inclined to go slow on ultra-expensive new projects.

To the ENGINEER of high ability

Through the efforts of engineers The Garrett Corporation has become a leader in many outstanding aircraft component and system fields.

Among them are:

air-conditioning

pressurization

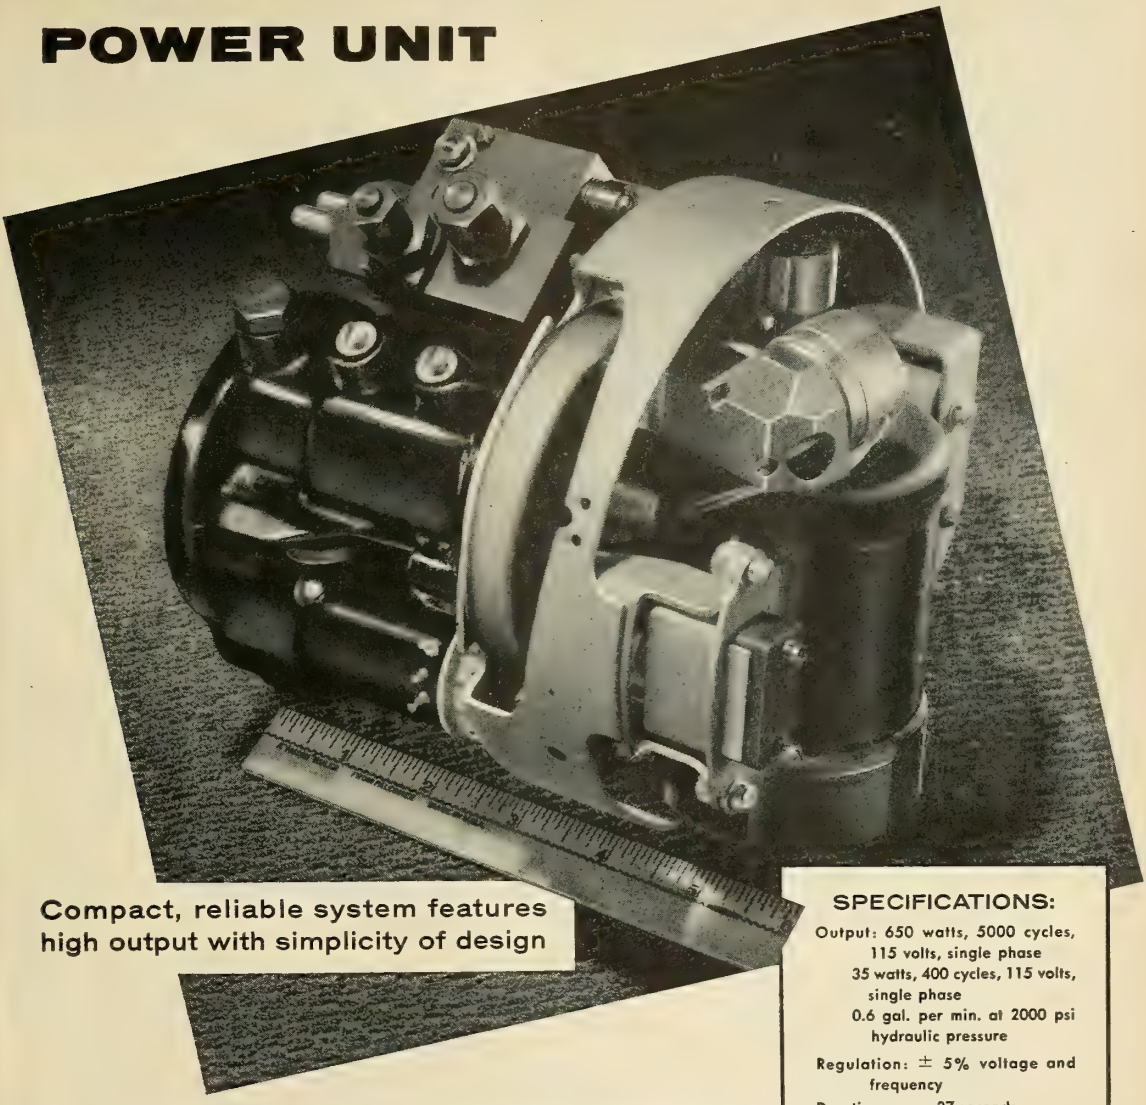
heat transfer

pneumatic valves and controls

electronic computers and controls

turbomachinery

The Garrett Corporation is also applying this engineering skill to the vitally important missile system fields, and has made important advances in prime engine development and in design of turbochargers and other industrial products.



Our engineers work on the very frontiers of present day scientific knowledge. We need your creative talents and offer you the opportunity to progress by making full use of your scientific ability. Positions are now open for aerodynamicists ... mechanical engineers ... mathematicians ... specialists in engineering mechanics ... electrical engineers ... electronics engineers. For further information regarding opportunities in the Los Angeles, Phoenix and New York areas, write today, including a resumé of your education and experience. Address Mr. G. D. Bradley

35 watts, 400 cycles, 115 volts, single phase
0.6 gal. per min. at 2000 psi hydraulic pressure

Regulation: ± 5% voltage and frequency

Duration:	27 seconds
Weight:	9.5 pounds
Size:	6.14 in. diam., 6.74 in. long

Ground power: compressed air

This AiResearch auxiliary power package operates the vital electrical and hydraulic systems in a missile.

Gases from a solid propellant spin the unit's turbine wheel at 50,000 rpm. The turbine's shaft drives the following: a 650 watt generator which supplies electrical power to run the missile's guidance system; a 35 watt generator which runs the missile's gyros; a hydraulic pump which in turn powers the servos that control the movable flight surfaces of the missile's airframe.

The hydraulic system features drilled passages which eliminate the need for potentially troublesome plumbing. It includes reservoir, filters, temperature compensator, relief valve, check valve, and squib valve within a single housing.

This auxiliary power system is an example of AiResearch capability in the missile field. Inquiries are invited regarding missile components and sub-systems relating to air data, heat transfer, electro-mechanical, auxiliary power, valves, controls and instruments.

What does it do between

HERE and . . .

THERE?

For the first time the behavior pattern of a free space Moving Target can be directly calibrated and immediately evaluated!

The proof of any guided missile is its performance. Not only is it necessary to provide accurate trajectory data in order to determine its effectiveness, but this must be made immediately available.

To meet both requirements is the purpose of the AN/FPS-16 instrumentation radar. This is the first radar developed specifically for Range Instrumentation. It has demonstrated its ability to track with accuracy in darkness, through clouds—under any atmospheric conditions—over extended ranges, and to yield data that can be reduced almost instantaneously to final form. This unit can also be assigned to plot performance of missile, satellite, drone and other free space moving targets.

In the past, this data has depended upon optical devices, triangulation systems with long base lines and precision limitations, modified radar equipment and data reduction methods often requiring months for computation. The immediate availability of data evaluation provided by the AN/FPS-16, now being built by RCA under cognizance of the Navy Bureau of Aeronautics for all services, is a great forward step in Range Instrumentation.

UNDERWATER MISSILES

A New Lethal Dimension in Unmanned Warfare

by Comdr. Charles W. Rush

AS A MEANS of delivering weapons against targets at sea or on land, the submarine possesses unique advantages over other weapon system. Cruising beneath the radar and visual detection stratum, somewhere in thousands of cubic miles of ocean volume, the submarine is not readily susceptible to being destroyed by surprise attack.

The advent of nuclear power has greatly enhanced the capabilities of the submarine. In addition to the almost unlimited submerged endurance and high speed which it contributes, nuclear propulsion makes the submarine a true all-weather ship. Not only can the nuclear-powered submarine ride out the worst storms in comfort and safety, it also can navigate under the Arctic ice-pack at any time of the year.

With the post-war change in the submarine forces' primary mission from destroying surface ships to sinking enemy U-boats, the requirement for a submarine-launched anti-sub weapon became paramount. Even the best anti-surface torpedo could not meet this new requirement—the problem had expanded into a new dimension.

Intensive research was applied to find a solution to the three-dimensional attack situation. The answer to this difficult problem was found in the conception of a homing torpedo that would guide itself to the noise emitted by a moving submarine. While this weapon unerringly seeks out a target sub, it is equipped with safety devices to protect the firing ship.

Another underwater-to-underwater weapon—one with a delayed action—is the submarine-laid mine. The submarine can first determine its exact navigational position, then lay these deadly "eggs" from its torpedo tubes in the location where they will do the most damage to enemy ships. Mobile mines have been developed which permit the submarine to remain outside an enemy harbor, while planting a minefield several miles distant.

After the war, the Navy recognized that the combination of the submarine and the guided missile would provide an effective system for deterrence of large scale aggression. In order to gain immediate experience with this system, the *Loon* missile, a modified German V-1, was fitted for shipboard.

Two submarines, *USS Carbonero* and *USS Cusk,* were equipped with launchers and radio command systems for guiding *Loon.* These early operations provided valuable experience, training, and testing for application to the higher-performance submarine missile systems which were to follow.

In 1947, the Navy initiated a program with the Chance Vought Aircraft Co. to develop a guided missile for launching from submarines. The result was the *Regulus,* a swept-wing, turbojet-powered, transonic missile capable of delivering an atomic warhead to a range of 500 miles. Two submarines, *USS Tunny* and *USS Barbero,* were converted to carry *Regulus* missiles.

In 1956, the Navy decided to complete the attack submarines *USS Grayback* and *USS Growler* as guided missile submarines. At the same time, construction was started on the first nuclear-powered guided missile submarine, *USS Halibut.* All of these submarines are designed to carry the *Regulus* missile.

Testing is now underway on *Regulus II,* a longer-range, supersonic replacement for the original *Regulus* missile. The configuration of all new air-breathing surface-to-surface missiles will be compatible with the new guided missile submarines, in order that the different missiles can be used interchangeably. This planning will expand the missile delivery capability of the new guided missile submarine. It will also extend the useful life of the submarine beyond the life of any one particular missile design.

(Ed. Note: To follow up the REGULUS II the Navy has the Triton development program, a Mach 4.0, 1500-mile range ramjet powered missile that will fit Regulus launching gear with only minor modifications.)

Spinning ball entering water at high speed leaves cavitation wake of water vapor similar to aerodynamic turbulent flow, exemplifying major underwater weapons system problem.

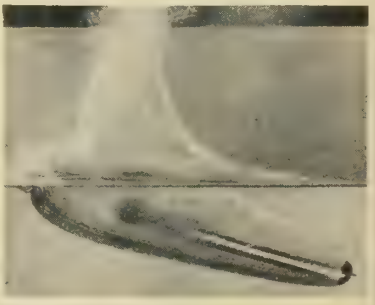
In addition to the air-breathing guided missiles, the Navy is working at high priority to develop a rocket-powered ballistic missile which can be launched from submarines. This is not an ultra-visionary weapon; its accomplishment is entirely within the current capacity of our missile technology.

One of the major areas requiring intensive development for successful utilization of long-range ballistic missiles is precise, all-weather navigation. Various new equipment being tested in the *USS Compass Island* promise to provide means of attaining the required accuracy, even under the darkest overcast conditions.

(Ed. Note: There are several approaches to precise underwater navigation. One might be the use of inertial systems similar to those now being developed for long range ballistic missiles. Another is the establishment of precisely located beacons on the ocean floor which could be "shot" the way aerial missiles now shoot the stars.)

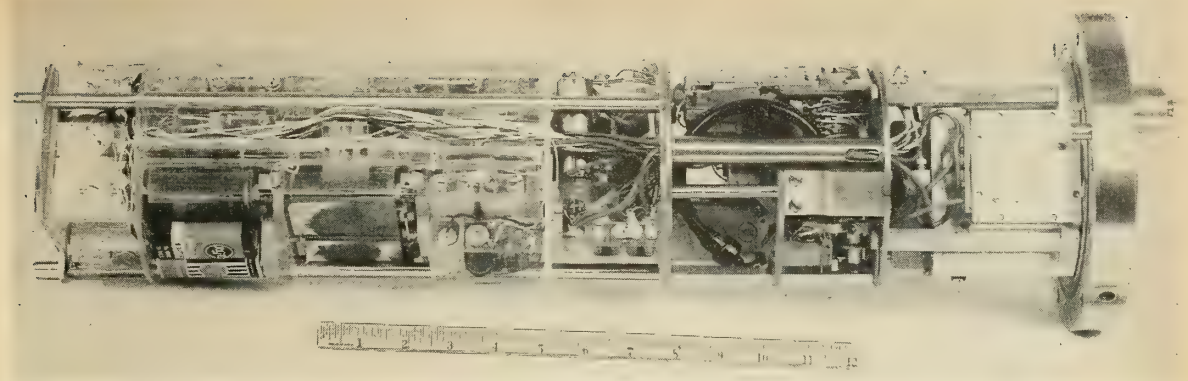
Our subs are equipped with two types of sonar: active and passive. Active sonar is capable of determining both range and bearing of submerged targets, but it must send out detectable energy to do this. Passive sonar does not transmit energy to the water, but furnishes target bearing information.

Against fast-moving targets, an automatic computer is needed for rapid analyzation of target and firing-submarine data. The trend in computer design is to equipment which resembles an electronic "brain." It must receive inputs from the sub's gyro-compass and underwater log, select data from the radar or sonar, perform complicated mathematical calculations in a fraction of a second, digest the data, predict the target's position on weapon arrival, and aim the weapon.



With the captain's permission, which he may give by throwing a switch, the computer can actually fire the weapon. Remarkably, computers have traditionally been one of the most reliable elements in our submarine weapon systems.

Future, foreseeable advances in submarine performance will place great demands on anti-submarine weapons. Submarines will run faster and deeper; weapons against them must follow. Our own submarines will be able to operate in the depths where enemy subs can be detected most readily; they must be equipped with weapons that have a high probability of sinking the high-performance submarine.



First, in order to minimize the time during which the target can evade and to reduce pursuit time after acquisition is made, advanced undersea weapons must be able to make high

A major hydrodynamic problem with torpedoes is that they may cavitate and

Showing that underwater instrumentation is not dissimilar to that required for airborne missiles, this assembly is used for studying the depths of the ocean. From left to right are: the battery and voltage regulator assembly; next, in order, comes the depth marker and pulse generator telemetering tube assembly and telemetering deck including servo-control tube for photomultiplier, pressure (depth) bourdon and linkage to microtorque potentiometer, function selector rotary stepping switch, ratchet relay, access plate to sealed photomultiplier and assembly aligning pin. A detailed study of the ocean's characteristics is vital to the successful development of modern underwater weapons systems.

speed. Secondly, as the maximum range of underwater detection equipment is increased, weapon range must be augmented to match. Enemy subs must be taken before they can strike.

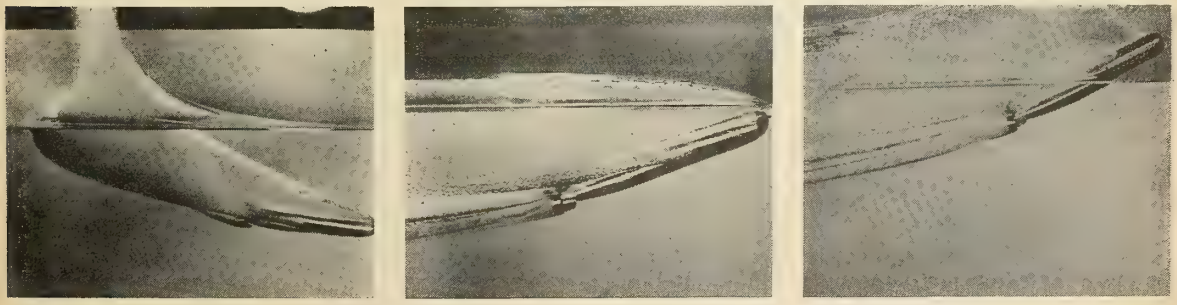
At torpedo speeds greater than approximately 50 knots, the screw propeller's efficiency and ability to transmit power to the water decreases rapidly. This is caused by cavitation, which also causes radiated noise to increase substantially. To overcome these difficulties, very-high-speed torpedoes must be designed with optimum hydrodynamic form and jet propulsion.

Underwater jets may be of two general types: rockets and hydroducts, corresponding to rockets and air-breathing jets in the atmosphere. The disadvantages of rockets for underwater - to - underwater applications are that they must carry all of the mass required for propulsion and that their velocity and efficiency are limited by the resistance of the viscous medium. In order to gain high speed while retaining long range, underwater jet propulsion vehicles will probably utilize the hydroduct principle, which uses ambient water to increase the mass flow rate.

Even jet-propelled torpedoes have practical speed limits, which will be reached when their velocity causes the waterflow to break away from the torpedo shell. At this point, cavitation will take place on the torpedo body in the same way as on the propellers of slower torpedoes at lower velocity.

Cavitation caused by the torpedo body will present serious control problems; depth and steering rudders will be acting in an unstable flow pattern, caused by cavitation bubbles forming and collapsing. Alternate methods of control, such as jet vanes or controlled jet streams, will be necessary to direct the very-high-speed torpedo.

As the ranges of detection and location equipments are extended beyond their present capabilities, greater weapon velocities will be needed. Time of flight must be kept sufficiently short to insure getting the weapon within effective radius of the target.



It may prove to be impracticable to design reliable underwater-to-underwater missiles with enough speed to reach extreme ranges in short enough time; thus, air-borne rockets may be the only feasible means of attaining the exceedingly high speed required.

(Ed. Note: This concept of the underwater-air-to-underwater missile is believed to be the subject of a development contract recently placed with Convair's Missile Division. Ideally, this missile would fit the torpedo tubes of current, conventional submarines and have a range of about 100 miles. This has been referred to as a Submarine Launched Inertial Missile—SLIM.)

Increased weapon range will give rise also to a requirement for new techniques to maintain terminal accuracy. One method of accomplishing this is to incorporate some type of remote guidance in the system.

It is feasible to adapt beam-rider guidance, similar to that used in anti-aircraft guided missiles, to underwater weapons. This will increase the probability of bringing the torpedo to within lethal range of the target at maximum range. Another possible means of increasing the kill probability at long range is to increase the lethal radius of the torpedo warhead. An atomic warhead could fulfill this requirement.

Recent technological advances—nuclear power, missile development, advanced hydrodynamics — have been advantageous to the submarine from the standpoint of both offensive and defensive power. A large expanse of rapid progress lies in the future.★

. . . due to uneven pressures to porpoise out of the water and off course.

Russia's Answer to Our SAC Bases

Development Of IRBM-launching Submarines Permits Soviet To Lag Behind In ICBM Work

by Anthony Vandyk

THE SOVIET NAVY's submarine fleet represents to Russia what the U.S. Air Force's Strategic Air Command represents to the U.S. SAC bases ring the Soviet Union. No major target in Russia is out of range of the USAF's B-52s.

For the Russians, however, no overseas bases are available. Even if the Red Air Force could obtain the use of bases in such countries where a strategic attack on the U.S. could be mounted, there is little indication that the bomber aircraft currently operated by the Russians would be suitable for use from such facilities. The Russians have not developed flight refueling anything like to the the extent that the USAF has pushed the technique. It is known that tests are being run for flight refueling the *Badger* (B-47 equivalent), but best intelligence information indicates that the big *Bison* (likened to the B-52) is not equipped for refueling in the air. The big 400,000 lb. turboprop *Baer* is likewise not equipped for flight refueling.

Without air bases and suitable flight refueling facilities for their modern bomber aircraft, the Russians would be in bad shape were it not for their submarine fleet. All evidence indicates that the Soviet submarines are in every way as efficient for Russia as SAC is for the U.S. The Russians have inherited all of Germany's know-how in the field of underwater warfare. The Red Navy took over most of what was left of Germany's World War II submarine fleet and certain construction facilities for underwater vessels.

In particular the Russians carried on development of the W-class long range submarine. The W-class submarine has a snorkel for submerged operation and combination diesel-electric powerplant and is a long-range ship.

The Russians also took over from the Germans underwater launching systems for guided missiles. There is evidence that much of the Red submarine fleet is fully equipped to launch IRBMs from underwater.

The Russian submarine fleet is currently in operational status. It does not remain in Soviet-dominated waters but sails to distant points in readiness for eventual operation.

Last month Senator Styles Bridges (R-N.H.) and m/r Managing Editor Erik Bergaust reported that a dozen submarines had been spotted off Cape Canaveral, Florida, where the U.S. are testing long-range missiles. "The story was not substantiated but we do know that the Russians spare no effort to

Two methods for launching underwater solid propellant rockets studied in this country are the tube-launching principle and vertical launching through the conning tower. Latter method might be employed for the Polaris. Both methods have been considered by the Russians.

learn what we are doing," Bridges stated then.

Other Russian submarines have been sighted near Japan, Newfoundland, and the Bahamas. The U.S. Navy does not comment on these reports but it is known that a large part of its current pre-occupation centers around the threat of the Red submarine fleet.

In the 12 years that the Russians have been working on the development of the German W-class submarine substantial progress has been made in several areas. Speed has been increased and range has been improved. But the most important development is the perfection of techniques for launching missiles from the submarines. It is estimated that every Russian submarine now under construction—production is at the rate of almost one a week—is equipped to launch an IRBM (FBM). The Russian submarine fleet in operation today includes between 400 and 800 vessels. Many of these are early models which are not equipped with missile launching facilities but probably at least a quarter of the fleet is comprised of modern types fully equipped for launching the IRBMs.

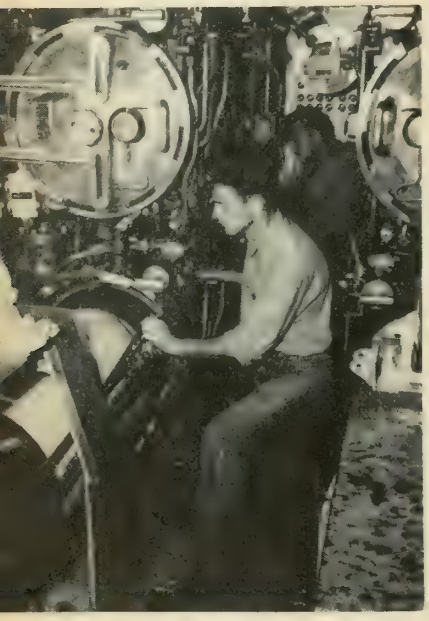
Though there's little reliable information as to the state of Russia's submarine missile art, they had a basis to start from 12 years ago—two methods for underwater launching worked out by the Germans but never put into actual operation. As reported previously in m/r, in one case small solid-propellant 21 cm *Borsig* rockets were mounted in external racks on the submarine's deck. These could be fired from under water by controls mounted within the submarine. This weapon system now is believed to have been developed to perfection by the Soviets. With this missile system the Red submarine fleet forms the greatest single threat to United States military security.

Even though U.S. anti-submarine warfare has reached a high state of effectiveness, it's still far from 100%. And with small-but-powerful nuclear warheads a reality, even 20% of Russia's submarine fleet launching even primitive missiles against our coastal cities could cause severe damage.

It is interesting to note that the Russians put great emphasis and faith in any weapon system developed by the Germans. In terms of missile systems, all major German concepts seem to have been adopted and accepted fully by the communists, such as the V-2, the *Reintochter,* the *Borsig* solid-propellant sub missiles, as well as the container-hauled V-2s.

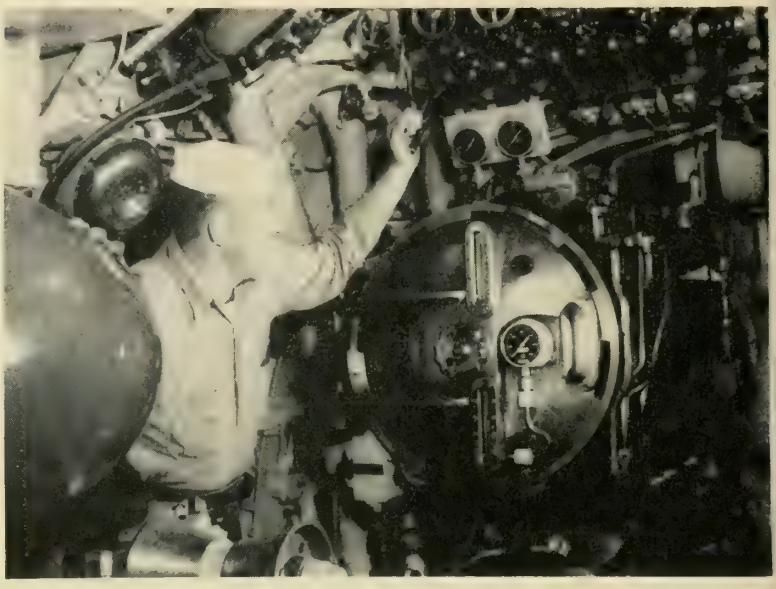
While the Russians had great faith in the Germans and their missile technology and capability, and while several German scientists have enjoyed high privileges in the Soviet since the last World War, indications are the Russians are getting tired of playing with German post-war hardware. They have activated several all-Russian missile programs, and there is no reason to doubt that an all-out submarine-missile program is heading the list.

In addition to submarines, the Soviet Navy has a number of surface vessels equipped as missile ships, but these are of relatively minor importance since they can be easily detected. The submarine poses a very different problem, particularly when equipped with underwater missile launching facilities. It is a very difficult target to hit. Certainly the Soviet submarine threat to the U.S. is every bit as serious as anything that has faced the nation. ★



While the Soviet is completely surrounded by our SAC bases, we are faced with the problem of being surrounded by their missile-launching submarines. The latter, of course, are less vulnerable; furthermore, maintaining SAC bases involves close negotiations with our allies.

Liquid propellant submarine missile can be carried to the surface in torpedo-type container launched through large tubes in submarine's hull.



and Off She Goes . . .

Crew on board USS Archer Fish is taking on torpedo for practise exercises. 21-inch diameter electric torpedoes of this type are acoustic. Westinghouse Electric Corporation is now working on sophisticated Mark 37 high-speed, long-range torpedo and Clevite Research and Brush Electronics are pushing a Mark 43 torpedo through test and development. Although most modern torpedoes are acoustic, advanced versions may employ wire or other guidance.

Launching of torpedoes is still tricky business and requires precision and coordination on the part of the entire submarine crew. A miss can be dangerous . . .

. . . but a hit can be rewarding. Especially if the target is a huge tanker or an enemy anti-submarine vessel. This picture shows a successful result after several days of chase. Tomorrow's torpedoes will be too fast and too accurate for an enemy ship to do any evasive maneuvering.

Undersea Missiles at Westinghouse

By James M. Beggs and Thomas H. Campbell, Jr.

Westinghouse Ordnance Department

IN AN AGE when ICBM and IRBM are daily conversation pieces, the *torpedo* has been stripped of much of its glamour. Probably none of the early torpedo designers envisioned that the modern airborne family of missiles are but latter day stepchildren of the first true guided missile, the *torpedo*.

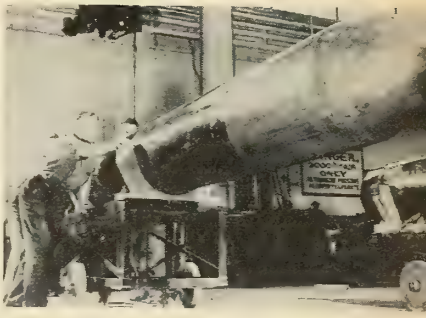
What of the future of the *torpedo as a missile* in the A and H bomb era? This question is easily answered by a spin of the globe and a comparison of water vs. land mass. The logistic mission of sea lanes remains and their ready access and control is as vital. Ship types, speed and propulsion may change but, in the final analysis, troops must occupy territory to control it. They, and air bases, must be supplied.

While our Navy experienced 60% duds in torpedo firing during the first year of the war, the Germans had a successful wakeless electric torpedo and the Japanese were operating an internal combustion torpedo of longer range and larger warhead than any in fleet use. The success of these weapons forced the Navy to look for advanced torpedo design on a "crash" basis and to seek greater production capacity than was available in Naval facilities.

In March 1942, a group of Westinghouse engineers with representatives of other major industrial concerns were invited to view the captured German electric torpedo and propose production bids. On the basis of the proposals submitted, Westinghouse was awarded a contract to develop the Mark 18 electric torpedo. Pressure of war operations and the extreme fleet need caused the Navy to place a time limit of 105 days for design and delivery of a prototype model.

The captured German torpedo was turned over to Westinghouse with the intent that a "Chinese copy" be made for American use. This was impossible since parts could not be adopted to standard manufacturing procedure, some functions were not fully understood and the torpedo could not be adapted for launching in the tubes of American submarines.

The Chinese copy idea was set aside and a major design and development project undertaken using captured knowledge as a starting point. Warhead, exercise head, control mechanisms and torpedo gyro were added to the original development contract and still the tight time schedule was maintained.



Westinghouse delivered the first model 104 days after receipt of contract and four additional models within 15 days after delivery of the first test vehicle. In conjunction with the development of the torpedo, Westinghouse was ordered to design and develop tooling capable of reaching a maximum production level of 300 units per month, and awarded a production contract. Quantity delivery of the electric torpedos began before the end of 1942 and the Mark 18 weapon was introduced to the fleet in 1943.

When the electric Mark 18 arrived in the submarine force the reception was somewhat less than enthusiastic. Submariners exposed to one device after another which proved faulty, had learned to compensate for some of these faults and were not anxious to be stuck with another dud.

The Mark 18 had slower speed, 28 to 30 knots as compared to 45 knots of the higher powered steam torpedoes and was looked on with disfavor. The first electric torpedoes were taken on war patrol on a voluntary basis. The Mark 18 quickly established a reputation. Submariners became acquainted with the wakeless feature which prevented detection until a hit was secured. the dependable depth performance which allowed shallower depth settings permitting firing at targets previously

The country's largest manufacturer of torpedoes during the last war Westinghouse still maintains leading position in the field. Torpedo output today is classified, but the series of pictures to the right clearly indicate production is going strong. Navy spends approximately $50 million a year for conventional torpedoes.

Enemy shipping sunk by submarine forces during World War II totaled 1,314 ships, greater than the total of all other armed forces. Tomorrow's torpedoes and missiles will be designed to hit surface targets and aircraft as well . . .

neglected, and the simple but reliable contact exploder it carried. The demand for the Mark 18 increased from 30% of torpedoes fired in 1944 to 65% in the last six months of the war.

Parallel with this development, Westinghouse engineers in conjunction with the Navy Laboratories, undertook the design of torpedoes with acoustic as well as electro-dynamic controls. This extensive development program resulted in several different models and culminated with the production of a guided underwater missile, the world's first full-sized, all-electric, acoustically controlled torpedo, utilizing acoustic phenomena to seek out and follow its target until a hit is secured.

These target-seeking torpedoes were put in active use by the submarine force just prior to the close of the war. At that time the enemy's scope of operations was reduced and there was a shortage of good targets for our submarines. However, this self-directed undersea missile sank a total of five Japanese ships and holds the distinction of sinking the last enemy ship in World War II.

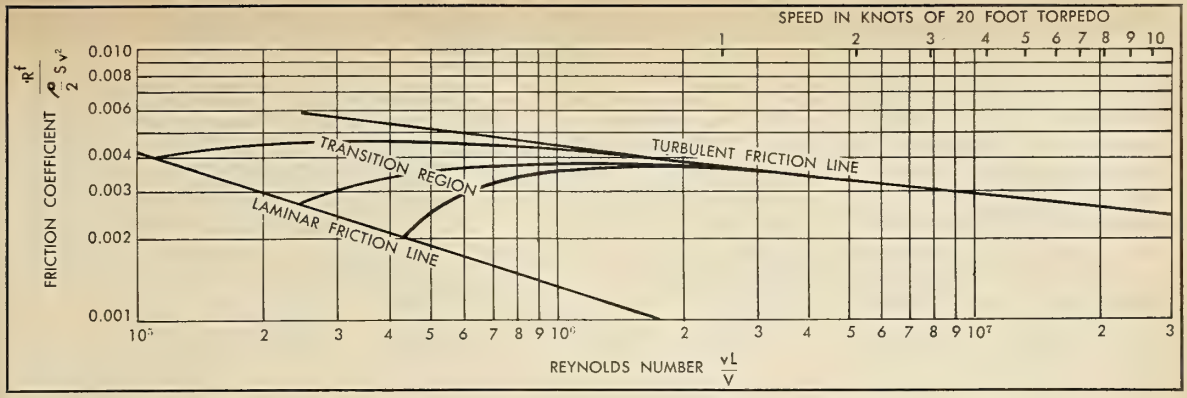
The enemy shipping sunk by submarine forces totaled 1,314 ships, greater than the total of all other armed forces. The Westinghouse electric torpedoes introduced at the mid-point when targets were becoming scarce accounted for over 400 ships.

During the interval between V-J Day and the Korean emergency, Westinghouse Ordnance halted production but continued in the field of underwater missile development and the field of sonar application, begun during World War II in cooperation with the U.S. Navy, Bureau of Ordnance. Much was accomplished in the field of miniaturization, control design, and underwater acoustic studies.

During the Korean conflict, Westinghouse Ordnance went into production of torpedoes for fleet use. During the two wars, a total of over 10,000 torpedoes were produced for the Navy.

At the end of the war in Europe, it was discovered that the German submarine force had a torpedo with a system for homing on the propeller noise of ships, giving chase and sinking them, a much more sophisticated system for guidance than that contained in their V-1 and V-2 rockets. It must be assumed that the Russians have access to this undersea missile and that they, as we, have the capability of using this "captured knowledge" to further the art of undersea missile warfare.

Since the self-contained undersea craft presents a grave threat as a launching platform for missiles and harassment to control of the sea lanes, weapons to combat this menace are extremely necessary in the NATO arsenal.



With this Russian capability, what are the problems facing our torpedo designers? The advent of the nuclear powered ships together with improved hull design, make possible higher and higher ship speeds, thus the torpedo of the future must have much higher speed to be effective.

Since the stowage capacity of submarines is limited, torpedoes of the future must be made more reliable and their kill capability must be increased. The history of modern weapons has been one of increasing complexity and the torpedo is no exception. With this complexity has come higher cost.

To justify this expense, our weapons must be increasingly effective and the torpedo of tomorrow must be able to detect, seek, catch and destroy with high probability of success any enemy target, surface or submerged, which ventures into open water.

Westinghouse Ordnance Department which was active in mine development and production during World War II as well as development and production of underwater missiles is continuing to maintain its leadership in the field of underwater ordnance. The company maintains as part of the Westinghouse Baltimore Defense Divisions, complete facilities for the development and manufacture of underwater missiles. This group of development engineers brings the skill and experience of acoustic, electrical, mechanical, electronic and hydrodynamic engineers to bear on the problems involved in developing for the Navy the newest type of underwater missile systems.

Since World War II through Navy-and-Westinghouse-sponsored research and development this group has developed and proven many of the latest concepts in the undersea missile field involving improved performance, speeds, accuracy and deadlines to keep our submarine force equipped to perform their mission in control of the sea lanes and carrying the combat action to the aggressor's waters.★

Beneath the Waves

By Robert Taggart
Reed Research, Inc.

WITH THE ADVENT of the true submersible—atomic submarines that can cruise at high underwater speeds for weeks on end—and with the growing practical knowledge of guided missiles of all types, the oceans assume a new strategic significance. This is why missile-makers now take another, different look at the fish and at birds like the diving petrel and loon.

The basic prototype for an underwater missile is the torpedo which has a long history dating back more than two centuries.

Perhaps the greatest technological change since World War II which affects torpedo design requirements is the complete revision in the concept of submarine warfare. The submarine was primarily a surface vessel which could submerge, when necessary, to stalk a target or to evade avenging anti-submarine vessels. Today, with the advent of nuclear power and other closed-cycle propulsion plants, the submarine is a true submersible.

This imposes a third dimension on torpedo design requirements. With the target free to evade vertically as well as horizontally, the missile must be able to follow these evolutions and strike home with deadly accuracy.

Thus it can be seen that the requirements for the underwater missile of today and of the future are altered drastically from those of the torpedo of World War II. It must attain high speed with a minimum of perhaps 60 knots. It must be silent both to avoid detection and to prevent acoustic interference with its guidance system. It must be capable of operation in three dimensions and of submerging to the maximum operating depths of submarines. The greater its range the more effective it will be.

First consider the speed requirement. Although the speeds of airborne and underwater missiles differ radically there are some similarities. In airborne missiles the sound barrier had to be overcome and now the thermal barrier presents a formidable problem. In underwater missiles similar barriers exist. The first is the turbulence barrier which has long been understood from the standpoint of practical underwater vehicle design.

The principal form of resistance to the motion of underwater bodies is frictional resistance. The amount of this resistance is a function of the surface area of the body and its speed. It is usual to plot this resistance-speed relationship on a non-dimensional basis with the resistance coefficient as the ordinate and Reynolds Number as the abscissa as shown in Figure 1. The resistance coefficient is a function of the frictional resistance, the density of the medium, the surface area, and the speed. The Reynolds Number is a function of the speed, the length of the body, and the kinematic viscosity of the medium.

The curve in the lower left of Figure 1 is the laminar line representing the resistance due to laminar flow over the body. As speeds are increased a transition takes place until a turbulent flow exists along the length of the body. As can be seen the resistance in turbulent flow greatly exceeds that in laminar flow and it can be noted that the transition from laminar to turbulent flow takes place at relatively low speeds. Assuming smooth underwater body 20 feet in length with a surface area of 100 square feet the typical frictional thrust versus speed curves are plotted in Figure 3. It is also obvious that if the body could remain in laminar flow throughout its speed range the

Shipjack, the first operational submarine using revolutionary Albacore hull.

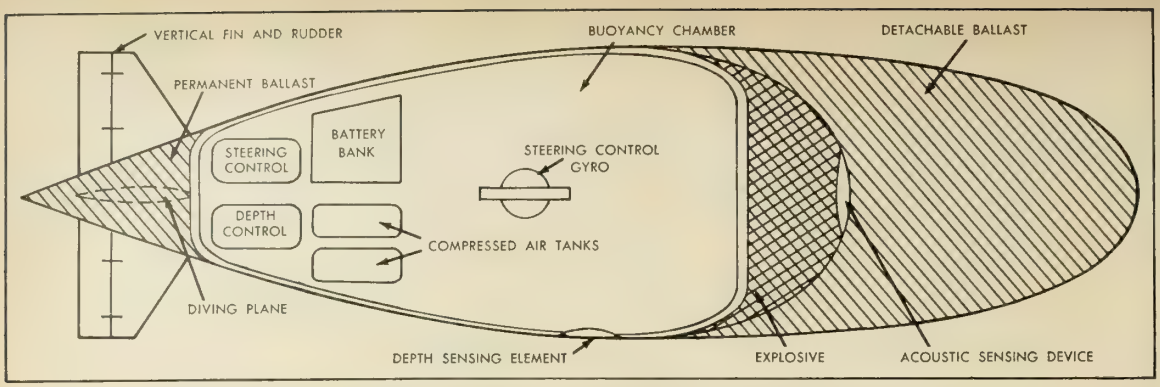


Figure 2. Drawing of possible propulsionless underwater Buoyant Ballistic Inertial Missile—BBIM.

thrust required for propulsion would be greatly lowered.

The cavitation phenomenon presents a more formidable barrier to high underwater missile speeds. As the velocity around a body or a propulsion system increases, the pressure drops. When this pressure becomes less than the vapor pressure of the water, air is pulled out of solution and bubbles are formed. These bubbles have many deleterious effects. They lower the density of the medium to such an extent that the propulsion device drastically loses efficiency thus limiting the top speed at which a missile can travel. The collapse of the bubbles as they enter higher pressure regions takes place with explosive force sufficient to erode away a propeller or control surface in a very short time. This bubble collapse is also a source of very high noise levels which render the missile easily detectable and interfere with its own acoustic guidance.

High underwater speed calls for a form design which varies somewhat from the conventional torpedo body. The total resistance of a submerged body consists of frictional resistance, roughness resistance, and form drag. The frictional resistance is a function of the wetted surface and the speed as shown in Figure 1. Roughness resistance is a function of the type of surface finish which is applied to the body. For a smooth, clean surface the roughness resistance is zero. For the average ship surface a constant addition of 0.0004 to the frictional resistance coefficient gives a resonably accurate estimate. For a well constructed and finished torpedo body an addition of 0.0002 is a fair average.

Form drag, for a well-designed underwater body, is a function of the wetted surface and the diameter-to-length ratio. As a general rule this resistance can be taken as one-half the product of the frictional resistance and the diameter-to-length ratio.

Because the wetted surface is such an important factor in high speed underwater form design it would appear desirable to contain the required volume within a form having a minimum wetted surface. The geometrical shape having the minimum wetted surface to volume ratio is a sphere. Yet if a sphere were used the separation of flow from the afterbody would be such as to make the form drag excessive.

For this reason it is necessary to use a more gradual curvature in the body profile but the symmetry around the axis is retained to form a body of revolution. The final form of a high speed underwater body usually has a blunt nose bordering on a hemisphere. The sections gradually increase in diameter to a point at about one-third the length from the nose and then taper gradually downward to a point, or small radius hemisphere, at the tail. Forms with diameter-to-length ratios on the order of 0.14 evidence the least total resistance for a body of practical dimensions.

There are methods by which the speed at which cavitation occurs can be increased. Since cavitation is a function of pressure, the deeper a missile operates, the less will be the possibility of its propeller cavitating. There are also some hydrodynamic tricks by which the pressure surrounding a propeller can be increased.

One of these tricks is to enforce a lower velocity upon the water as it passes through the propeller. Due to the theorem expressed by Bernoulli, as the velocity decreases, the pressure increases. This can be accomplished by the ducted propeller or pump jet.

Although this design serves to delay cavitation it also enforces an efficiency loss. The interior and exterior surfaces of the duct create an additional wetted surface which adds to the frictional resistance and to the pressure drag. Propulsive efficiency, which is in part a function of the diameter of the jet stream, is also reduced. The overall loss in propulsive efficiency due to these factors is often prohibitive. Various adaptations of this principle, such as the hydroturboprop and the hydroturbojet face the same limitations.

The next logical consideration might be rocket propulsion. Rocket systems have been outstandingly successful in airborne missiles, and hence they would appear to have possible application to the propulsion of underwater missiles. Liquid propellants can probably be ruled out because of the difficulties of handling fuel and oxygen aboard ship. Although storage and transfer systems for these lethal liquids have been worked out, they are extremely undesirable and would not be tolerated unless the justification for their use were overwhelming. Solid propellants do, however, present a distinct possibility for underwater use. In fact weapons already developed employ this means of propulsion in the water. Yet there are many shortcomings to underwater rocket propulsion which should not be overlooked.

Due to the reaction principle, rocket propulsion eliminates the cavitation problem insofar as propulsive efficiency of the missile is concerned. But due to the high velocity of the jet stream relative to the surrounding water, cavitation further aft in the stream is bound to occur which will be a source of excessive noise.

Rocket propulsion is also inefficient from both the propulsion and the resistance standpoint. The efficiency of a rocket propulsion system is a function of the relative velocity of the jet blast and the missile. Since the speed of the missile in water is low compared with its speed in air, the efficiency of the propulsion system is low. The propulsive efficiency is also a function of jet diameter but as the diameter of the afterbody of an underwater missile in-

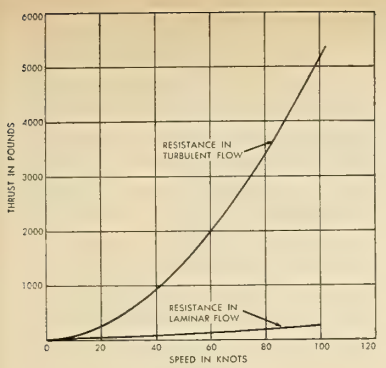

Figure. 3.

creases, so does its resistance.

Thus, although it appears that rocket propulsion with solid propellants may be a partial solution to the underwater missile problem, a number of difficulties remain to be overcome.

Smaller fish such as the swordfish are said to attain speeds in excess of thirty miles an hour. All slender game fish such as the marlin, wahoo, and dolphin are credited with high speed. The 1946-1947 British Scientific Expedition to the Antarctic Whaling Ground made what are considered to be reliable measurements on the speed of whales. Even a lumbering 120 ton, 90 foot monster can attain a speed of 20 knots for a short burst of about 20 minutes duration, and can maintain a speed of 14.5 knots for two hours or longer.

The great maneuverability of the fish appears to lie in his ability to contort his body at will in a manner best adapted to the desired maneuver. This ability is accentuated by the fact that his propulsion and maneuvering mechanisms are integrally related and his full thrust can be directed along the line of the maneuver to be effected. His maneuverability seems also to depend upon size, the whale being probably the least maneuverable of all fish. Yet even the whale can dive and turn with an ease yet unattained by man-made under-water craft.

In studying the propulsion of fish it appears that phenomenal results are achieved in translating muscular energy into propulsive force. One plausible explanation of this phenomenon is that fish actually operate in laminar flow in spite of operation at Reynolds Numbers at which turbulent flow would be expected. Studies on coatings and pliable materials are now being made in an attempt to duplicate this characteristic which has so great a potential value if it can be realized.

The propulsive machinery of fish, being primarily muscle, is silent. His propulsion device, the undulation of body and tail, also appears to be surprisingly noiseless. Studies conducted by the Woods Hole Oceanographic Institute have shown that high speed starts and stops and sharp maneuvering of porpoises produce no apparent cavitation. Indications are that large fish can move at top speed without producing any detectable cavitation or turbulence noises.

Another possible solution to the propulsion problems of high speed underwater missiles is the elimination of propulsion systems entirely. Two forces are available to an underwater missile which may be used to move it through the water—gravity and buoyancy.

One concept of a missile employing these forces is shown in Figure 5. A heavy, detachable ballast weight forms the nose cone. When this cone is in place the missile is excessively heavy in the water. Upon release from a surface ship, aircraft, or submarine, it would drop straight for the bottom reaching a terminal velocity which would be determined by its waterborne weight and its resistance. Control of the diving planes could convert this vertical motion into a glide path at an angle of perhaps as little as 30 degrees with the horizontal. At the greatest depth available the nose cone could be released at which point the missile would become buoyant. It would then rise reaching a terminal velocity determined by the buoyancy and the resistance of the new and smaller form. Again diving planes could be controlled to force the missile into a glide path leading it away from the launching vessel and toward the target.

A gyroscope is provided for directional control and a pressure sensing diaphragm is included to determine the release point of the weighted nose cone. In the nose of the buoyant body an acoustic sensing device is shown which could be used to control steering and diving planes to direct the missile to the target.

The potential of such a missile can best be shown by estimating the performance of a hypothetical design. Using the general configuration of the missile shown in Figure 5 with a length of 18 feet and a diameter of 4 feet, the displacement would be on the order of 9000 pounds. If the nose ballast were a solid steel casting its weight would be about 15,000 pounds. Assuming the weight of the structure and warhead to be 2000 pounds the excess weight would be 8000 pounds. In the dropping phase this missile would reach a terminal velocity on the order of 70 knots in a vertical direction. At a 30 degree glide angle this speed would drop to about 30 knots.

After release of the nose ballast the reserve buoyancy would be about 7000 pounds. During the rising phase of its trajectory the missile would achieve a terminal velocity of about 25 knots on a 30 degree glide angle increasing to 60 knots on a direct vertical rise. A typical trajectory is shown in Figure 4.

This type of missile would be relatively quiet and would be inexpensive. Cavitation would not be a problem. It would be limited in range and in maneuvering flexibility. Its greatest value would be realized in water of great depth which is the controlling factor on range.

Missiles with undulating bodies and underwater ballistic missiles offer interesting possibilities and some food for thought. They are probably not a complete solution for the ultimate in underwater missiles. In fact their deficiencies in this respect have been pointed out. It is quite possible, however, that the fundamental principles upon which they are based may serve in combination with other propulsion schemes to finally evolve a missile which satisfies all requirements. ★

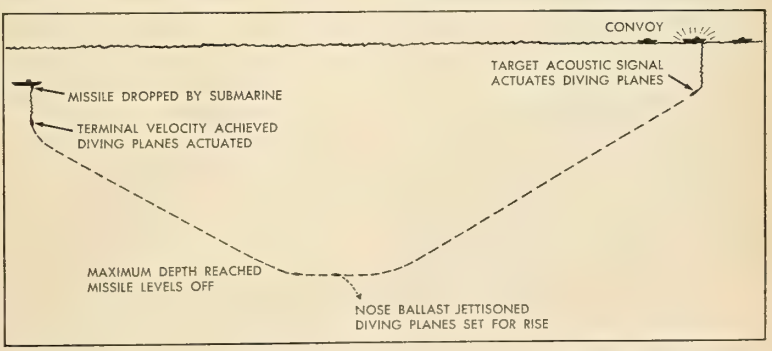

Figure 4. Diagram shows possible trajectory of proposed Buoyant Ballistic Inertial Missile—BBIM—a short-to-medium range missile traveling in absolute silence and not requiring any propulsion system whatsoever. This missile is not an active project but is described to illustrate some of the wholly new approaches possible in water. A variation on this concept using gas cylinders and buoyancy tanks might conceivably be used to transport an IRBM missile across the ocean for launching at the land mass of Europe. By alternately flooding and blasting out tanks it would travel sine wave course—up and down limited only by gas cylinder capacity.

TOMORROW'S TORPEDO

Future underwater torpedo development faces a long hassle with one of the most stubborn elements scientists could encounter—seawater.

This stubbornness is especially evident in guidance and propulsion.

Traditionally the torpedo is preguided. Before launching, its course has been established internally through gyroscopic stabilization and guidance mechanisms programmed for a given pattern.

But in this age of high speed and high maneuverability, the torpedo must now cope with rapidly changing conditions after it is fired.

This means the torpedo must carry its own capability.

Three possible means of detection are: acoustic, radio frequency and infra-red techniques.

Transmissibility of infra-red in seawater is practically nil. At this time there appears little chance for successful use of this part of the spectrum for torpedo guidance.

Underwater radio-ranging offers little hope for underwater detection at any of the frequencies that might be practical for torpedo use.

A good example is the very low frequency communication system used by the Navy for keeping in touch with its submarines around the world (even those that are submerged), which transmits on about 10,000-15,000 cycles. Its antennas cover an area measured in miles, and power output is in megawatts.

The acoustic method of detection seems to have won out for currently operational torpedos. A Westinghouse torpedo on display recently had a rubber diaphragm in its nose.

It is believed an acoustical system is carried by this new torpedo for detection of its target. Whether the device uses sound generated by the target or reflections of sound generated by the torpedo and reflected off the target is not known.

The World War II technique, turning off all noise generating equipment in order to escape detection, would do no good against a torpedo with noise generating equipment.

The need of torpedoes as three-dimensional weapons complicates acoustical sensing problems. Advent of the atomic submarine, and the concept of submarine-launched intermediate range ballistic missiles, means torpedoes must find and destroy the launching submarines.

For this reason depth must be added to operational capabilities.

This restricts the various detection methods to be considered.

Even now, with acoustical guidance, sea water does not present a medium of uniform transmissibility to sound.

Temperature changes rapidly from point to point, and so does the pressure. To these variations can be added other spurious signals reflected from objects other than the target, such as the ocean bottom or schools of fish.

One of the most urgent needs for future torpedoes is the ability to predict future position target.

This need is similar to problems encountered in firing non-detection types of rocket weapons against other aircraft. The speed of both the launching vehicle and the target vehicle must be known and the information used to calculate a collision course.

Submerged speed of the new atomic submarines has not been disclosed. However, they are believed to be of such a high velocity that new types of torpedo detection and prediction equipment must be developed to cope with the problem.

The first electrically driven torpedoes were used by the Germans during World War II. They had the prime advantage of leaving less of a tell-tale wake than bubble-producing steam motors.

Present day torpedoes are electrically powered by motors little larger than ordinary five horsepower motors. However, they deliver "many, many times five horsepower."

As the torpedoes are planned for use at lower and lower depths, the pressure problem mounts. Hull strength becomes a paramount concern of any new torpedo design.

From purely a propulsion point of view significant successes have been achieved in research and development work with more sophisticated types of propulsion. In many cases these parallel those used for airborne and space-bound missiles—ramjets and pure rockets. Speeds triple those of World War II torpedoes have been achieved in special full-scale test tanks.

The main draw-back has been and remains that these missiles are extremely noisy. Also, unlike the electric torpedo, many leave an all-too-obvious bubble wake. This gives the target two methods of detecting the attack missile—visual and acoustic.

In addition, there is still no known hydroform that can travel at 100-knot speeds without cavitating. This phenomenon is a major source of noise in itself. However, work now underway to develop methods for providing boundary layer control for subsurface vehicles, if successful, will revolutionize the basic concepts of undersea warfare.

One view of the torpedo of tomorrow might be as follows: Its body will be made of magnesium, plated to provide a smooth high gloss finish. Its detection and homing gear will be acoustic; will have a range of well over 100 miles if necessary; and will concentrate in the ultra-low frequency ranges. Its speed may be anywhere from 150 knots upwards. Its propulsion system will consist of a hydroduct (ramjet) whose "combustion" products are either heavier-than-water solids or solubles, thus leaving no visible wake. Hydrodynamically, it will be near-perfect, providing means of pressure equalization (boundary layer control), perhaps with ducts to feed in or draw off water as necessary. Its range may be anywhere from 10 to several hundred miles. Its warhead will be either nuclear or with conventional explosives.

Another factor in torpedo design is the need for operation more than once. A torpedo is fired only once "in anger" but might be fired a number of times for tests.

A one-shot electric motor might be designed for a very high efficiency if it were to be used just once. But the motors used in torpedos must be capable of both repeated use and high efficiency.

Thus far most torpedo research and development has been done by government laboratories. The product of this work was then handed to industry for integration in a weapon.

With the increased need for torpedoes for use against missile-launching-submarines and perhaps an anti-torpedo torpedo, the systems engineering approach becomes more necessary, as it has in atmospheric and space missile designs.

At least one company plans development of torpedoes on a systems engineering basis.

UNDERWATER PROPULSION

Engineering Horsepower to Velvet Hooves

IN WORLD WAR II, the submarine revealed its full potential for destruction, and among the steps taken to cope with the menace to our shipping was the application of the then newly developed techniques of sonar to electronically control the steering of a small electrically-propelled torpedo. This passive-acoustic homing torpedo was perhaps the first "guided missile" in the sense that we know it today.

But spectacular advances in underseas warfare capability have occurred with the advent of nuclear-propelled submarines, and the simple battery-propelled torpedo of the immediate post-war years is useless against such submarines, both from the speed and deep-diving standpoints. Modern weapons are needed for the anti-submarine defense of future years. Although some refinements are possible in both batteries and electric motors, it is obvious, from the energy requirements involved, that some kind of thermal propulsion will be needed in torpedoes capable of attacking, say, a submarine like the Nautilus.

The problems of thermally propelled, high-speed, deep-diving anti-submarine missiles are yet to be solved completely. The powerplant developments have much in common with airborne guided missile technology, but are distinctly different because of the fact that the torpedo is "flying" in a surrounding of water rather than air or space. Some of the special problems of anti-submarine torpedo power-plants are structural integrity, acoustic silence, the effects of deep operation on power-plant performance, and the utilization of "exotic" fuels.

For this comprehensive roundup on progress in modern underwater missile propulsion systems, m/r is indebted to the U.S. Navy Bureau of Ordnance which performed in accordance with the highest traditions of the Naval service. This article is a combination of two received—one by Jack W. Hoyt, Naval Ordnance Test Station, Pasadena; and one by G. G. Gould, J. F. Brady, S. Wolf and R. M. Dunlap, Naval Underwater Ordnance Station, Newport, R. I.

In general, all torpedo propulsion systems consist of an energy source, a feed system, a device for converting the stored energy into torque and a device for converting torque into thrust. For extremely high speed vehicles, the conversion of stored energy into thrust may be accomplished directly in a reaction chamber-nozzle assembly.

In 1903, the first turbine-driven torpedo was produced by the Bliss-Leavitt Company from 1905 through World War II, all U.S. thermal powered torpedoes have used turbines as prime movers.

Electric torpedoes started with the Foster torpedo in 1872. This torpedo, as well as the more successful Sims-Edison in 1877, was controlled and powered from a shore station by means of a trailing wire. For want of a satisfactory battery, development of electric torpedoes was abandoned in this country. The Germans however, placed them in service in both World Wars.

The characteristics of torpedo energy sources are the same as those for guided missiles with one major exception. For reasons of stealth, the torpedo should have no wake. Its exhaust, if any, should have a predominance of condensable and soluble products.

For certain applications the range and speed requirements of the torpedo are such that a relatively low energy storage capacity is required, which favors battery-motor propulsion. These also have the advantages of no wake and performance independent of depth.

The World War II electric torpedo used a conventional lead-acid battery. Now, Silver cell batteries (Zn-alkali-Ag202) are up to six times lighter and five times smaller than lead-acid batteries for the same output. Primary batteries such as the magnesium sea-water-silver chloride are even lighter and smaller.

For the higher speed, longer range torpedoes, total energy requirements are such that thermal power plants must be used. A wide variation in performance is achievable, depending upon the propellant combination. Because of their relatively high performance

New Bedford shoemaker Wm. Cunningham's rocket powered torpedo was way ahead of its time when, in 1894, he touched it off in the road before his house. The only casualty was a fire in the local butcher's icebox. Unfortunately, it never found its way into the Navy's Arsenal.

and their potentially wakeless exhaust products, hydrogen peroxide-hydrocarbon systems have been widely used.

Use of either carried fresh water diluent or free sea water diluent is necessary in turbine propulsion systems in order to decrease the operating temperatures. The use of sea water, although significantly increasing the performance per unit of carried expendables, poses the serious salt problems.

For reciprocating engine power plants, no diluent is necessary. Copious quantities of sea water are required, however, to cool critical engine parts.

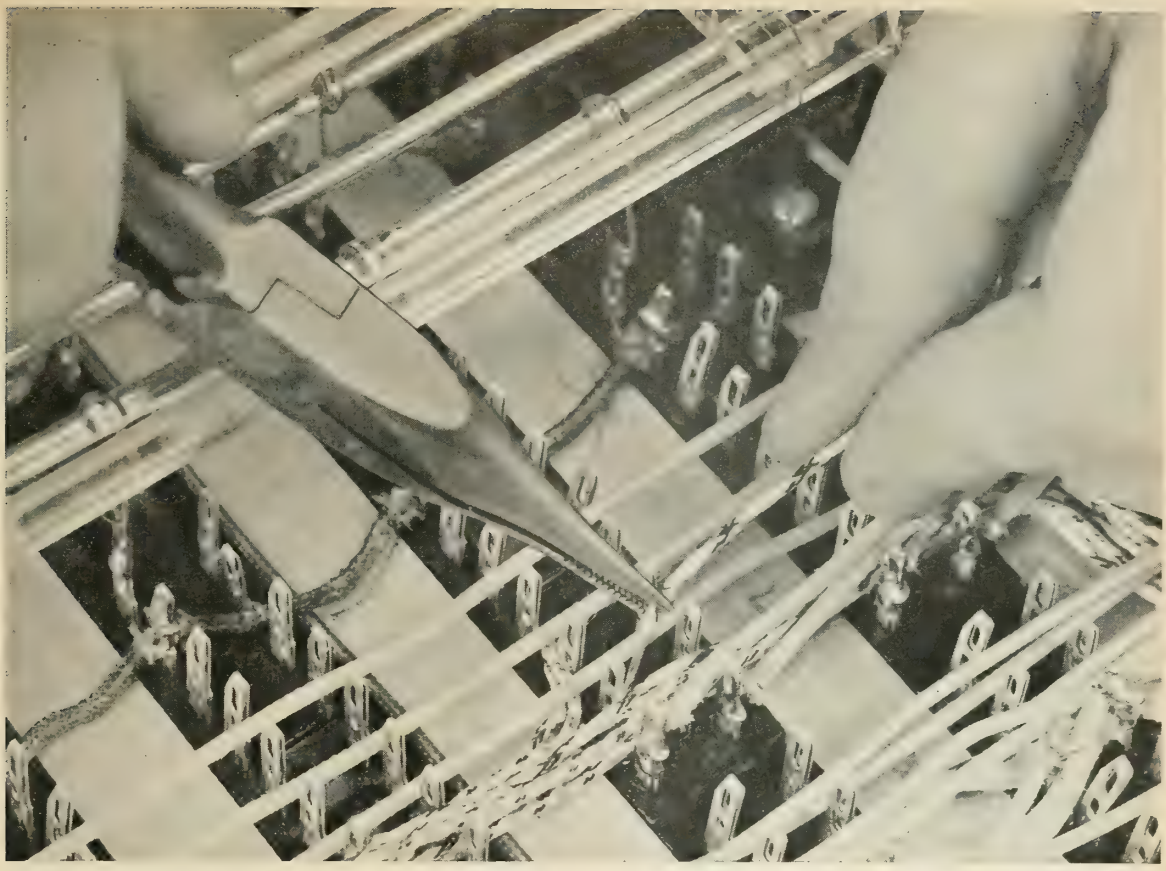
Monopropellants, although attractive from a simplicity point of view, are relatively low in performance and, in general, have a high percentage of non-soluble gases in their exhaust.

For torpedo application, solid propellant systems are attractive because of their simple mechanical construction, minimum number of parts, simplified handling and lack of feed system requirements. As a result of the system simplicity, its reliability should be high. The disadvantages of solid propellants as torpedo energy sources are the large quantity of non-solubles in their exhaust (wake) and their inflexibility in packaging to obtain a desired gas generation rate.

As undersea warfare is largely a matter of listening, it is paramount that a weapon be quiet.

Another requirement for the torpedo propulsion plant is small size and weight, particularly for the aircraft launched torpedoes. Overall weapon system weights are often lower than 400 lbs.

It is the deep-diving requirement that makes the ASW torpedo powerplant problem really unusual.



The high back pressure encountered at deep submergence strongly influences the choice of thermal powerplant employed in the missile—should it be a reciprocating engine, or should a turbine drive be used? Actually there appears to be, as in aircraft propulsion, definite regimes in which one or the other method has a weight-volume advantage.

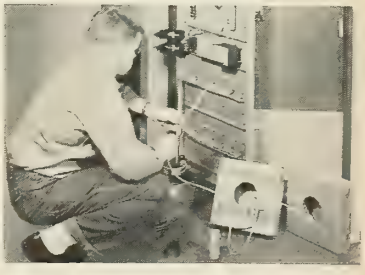
Generally speaking, American practice indicates that in the lower power levels, say under 100 or so horsepower, the engine drive is a more economical thermal system, but above this level, turbine drives are better. Torpedo reciprocating engines operate on essentially a "steam-engine" cycle, which is less affected by back pressure than the simple turbine cycle; this advantage is outweighed by greater powerplant bulk as the power level increases. Torpedo turbines are usually of the partial-admission axial-flow type; the high back pressure penalizes the small power level turbine due to high windage losses. As the power level is increased, this penalty diminishes.

Partial admission means that gases are admitted to only a portion of the periphery of the turbine—while the remaining blading churns relatively stagnant gas. As the back pressure on the

Striking demonstration of the similarity between aerodynamics and hydrodynamics, this model of a Chance Vought F4U was put in water tunnel to study turbulence in high subsonic range.

Memo to control systems manufacturers:

If you've got a really tough cable problem, Rome's cable specialists can solve it



One sure way to solve your really tough cable problems is to call in a cable specialist. At Rome Cable you'll find a complete group of specialists—men experienced in the design and manufacture of conventional *and* special wires and cables.

Femco Inc.—a communications and control systems manufacturer—recently turned to Rome's engineers for the communications cable in one of their unique control systems. Special heat- and moisture-resistant, rubber-insulated cable—consisting of twisted pairs with one pair shielded—was designed. Rome Cable built 50,000 feet of it to interconnect Femco's Pagephone stations. A standard heat-resistant thermoplastic machine tool wire was used for the pit cover control.

Cable that best meets your need

As Femco Inc.—and many others—have learned from experience: you get exactly what's required to do the job from Rome Cable. If *standard* wire and cable are adequate for the job, Rome's engineers will recommend that you use them. If, on the other hand, you need a *special* cable, they'll design and build whatever your equipment requires. Our years of experience in handling difficult cable-building assignments can be of real value when your cable problem is really a tough one. Why don't you let us give you a hand?

Contact your nearest Rome Cable representative for more information—or write to Department 400, Rome Cable Corporation, Rome, New York.

SPECIAL CABLE FOR FEMCO. Rome's engineers designed a special cable to interconnect Femco's Pagephone stations. 50,000 feet of custom heat- and moisture-resistant Pagephone cable were supplied by Rome Cable for this unique application.

turbine is increased to, say, the 500 ft. submergence level, the power absorbed in this churning (the so-called "windage loss") becomes appreciable.

The high windage losses of axial-flow torpedo turbines has led to the consideration of tangential-flow machines of the type manufactured by the Terry Steam Turbine Co. These turbines appear to have a windage loss similar to a smooth disk, and although their aerodynamic performance is perhaps less than that achieved by axial-flow units, their shaft output is relatively constant over a considerable range of depths.

Because of their simplicity, reliability, wakelessness, and insensitiveness to depth, electric propulsion systems have always been attractive. Unfortunately, the power-to-weight ratio of such systems has always been low. Design effort, therefore, has been expanded to development of high power-low weight electric motors. An obvious method for improving the power to-weight ratio is to increase motor speed. This necessitates either high speed propellers or a gear reduction.

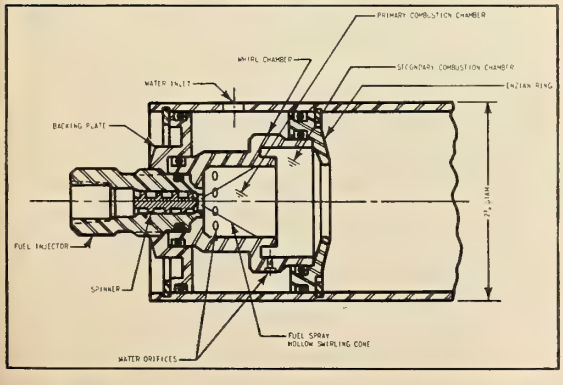
Unfortunately, experience has shown that either alternative results in higher radiated noise. Counter-rotating electric motors serve to increase power-to-weight ratio without requiring gear reducers. Considerable improvement, noisewise, is obtained thus.

Except for electric drives, the turbine has been the traditional power plant for U.S. torpedoes. Overall prime mover efficiencies of the pure impulse turbine (including gear train losses) of approximately 48% are being obtained, compared with the turbines of jet aircraft and of stationary power plants which obtain 85-92% efficiency. A perhaps more important criterion is the working fluid through-put required per unit of power. Representative values for various types of turbine systems are as follows:

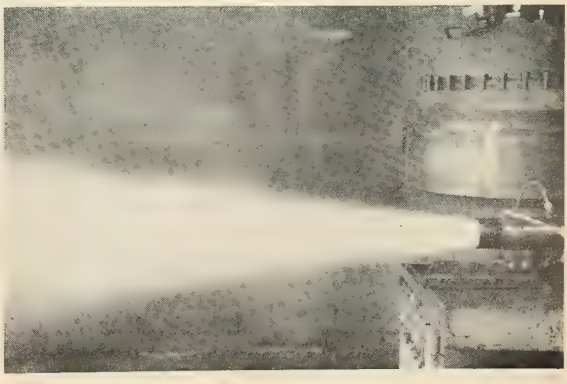
Steam power plant .	7.46 lbs/HP hr
Aircraft turbo prop engines	15.4 lbs/HP hr
Torpedo turbine ...	12.0 lbs/HP hr

Considering the torpedo turbine's compactness, it compares quite favorably.

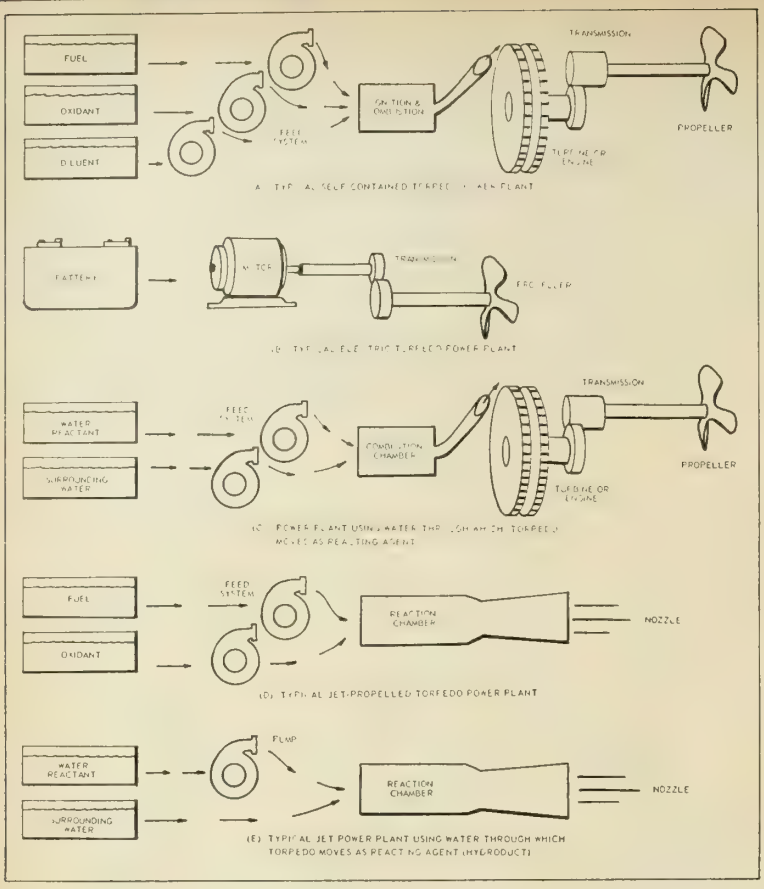
In brief, the trend in torpedo turbine design is toward higher rotative speeds, more arc of admission, higher inlet temperatures, and improved gas passage design to reduce shock wave problems. Consideration is also being given to multi-stage units to more efficiently handle the high pressure ratios.



Recent advances in metallurgy, however, allow us to increase speeds to more favorable values. For example, at 1200°F Inconel "X" has a working strength of 74,000 p.s.i. compared to 11,000 p.s.i. for 8630 steel. Thus, at 1200°F Inconel "X" wheels may be run at speeds 2.5 times as fast as wheels made from 8630 steel.

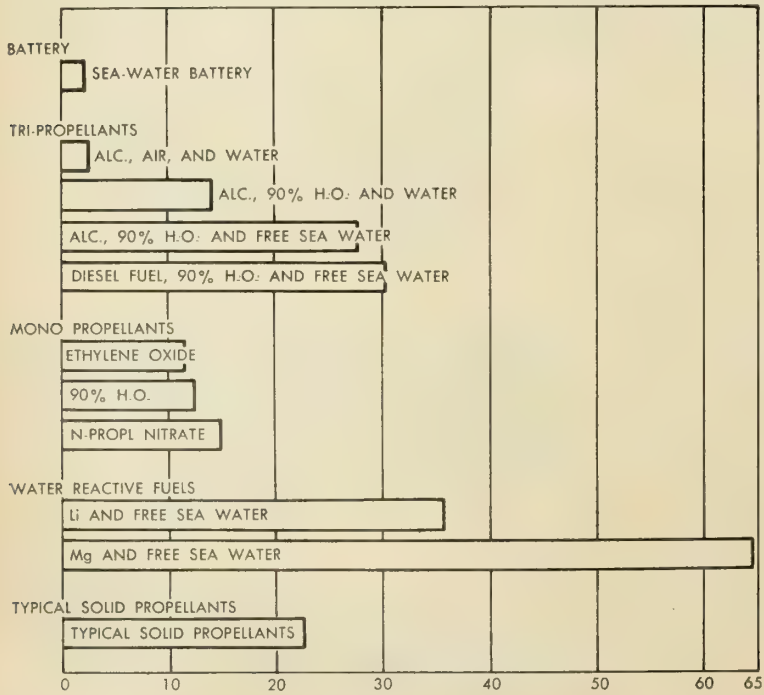


Arc of Admission: To date, torpedo turbines have utilized less than 25 per cent of the available arc of admission. If the entire arc were used, four-to-five times more power would be obtained than is required. To utilize the full arc of admission, without producing tremendous quantities of power, requires reduction in the size of the machine. To maintain a good ratio of wheel to jet speed, the rpm of the machine must be increased. Advances in bearing design now permit running at speeds above 50,000 rpm whereas a few years ago 10,000 rpm was considered high.



Because of their high efficiency in the lower power output range, their ability to operate without a diluent, and their lack of windage problems, reciprocating engines are competitive with turbines for certain applications.

Early torpedo reciprocating en-



Combustor for torpedo turbine drive resembles rocket motor. To the left is a schematic drawing and to the right the combustor is shown on a static test stand, looking much like a rocket.

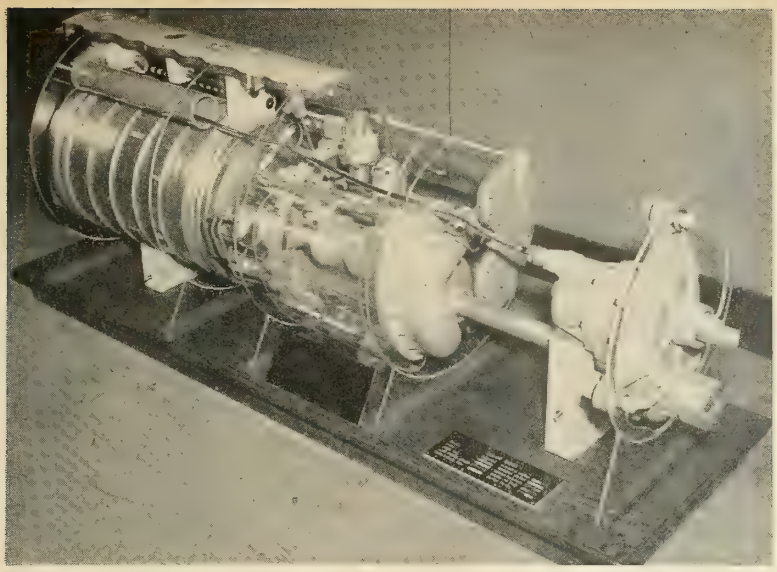
Above are the basic layouts of five possible torpedo propulsion systems reading down in the order of their sophistication. Below, their theoretical comparative performances are charted.

gines were similar in most respects to conventional steam engines, running first on compressed air and later with hot gases burned in an external combustion chamber. Air was first used as the oxidant, and more recently, hydrogen peroxide. One version of the engine uses peroxide decomposition products as the oxidant while other experimental engines utilize direct injection of liquid peroxide into the cylinders.

Most torpedo reciprocating engines operate on a two-stroke, modified Brayton cycle. A four-stroke cycle torpedo engine was developed by the Germans during World War II, but not placed into service.

Numerous mechanical engine designs have been made. Three and four cylinder radial, four and eight cylinder "V," horizontal opposed piston, and various barrel-type configurations have been tried.

The major problems still to be solved include valving, cooling, and reliability. Reciprocating engine design still remains more of an art than a science. The solution to most problems must be obtained by "cut and dry" methods as opposed to the refined theoretical work that may be accomplished on other types of prime movers.



Devices analogous to the aeropulse, the turbojet, and the ramjet are practicable for underwater propulsion. These devices are the hydropulse, the hydroturbojet, and the hydroduct respectively. Use of underwater rockets, although technically feasible, is impractical except for extremely short ranges because of the unfavorable ratio of torpedo-to-jet speed.

Although all the above jet devices are promising for torpedo propulsion, their use will depend upon the requirements of the future.

The power plants described above require extensive testing to ensure that they function reliably under all conditions of operation.

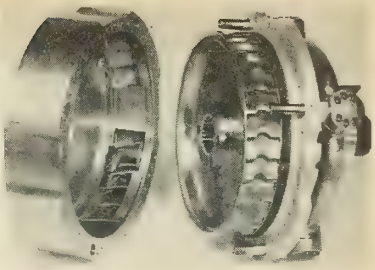
Many of the questions concerning the components respond to conventional test techniques. Some do not. Take for example, simulation of the operation of a gas turbine and combustion system driving a torpedo in 1000 feet of sea water, corresponding to a back pressure of 444 p.s.i. with combustion chamber pressures of perhaps 1800 p.s.i. Containing and controlling these pressures, absorbing the power and extracting the performance data becomes a formidable problem. So does measurement of differential pressures across flow control orifices.

Noise output of torpedoes is measured while the torpedo is running, both captive and free. At the Underwater Ordnance Station in Newport, R. I. is

A modern torpedo reciprocating engine including fuel tank, oxidizer tank, accessories, controls.

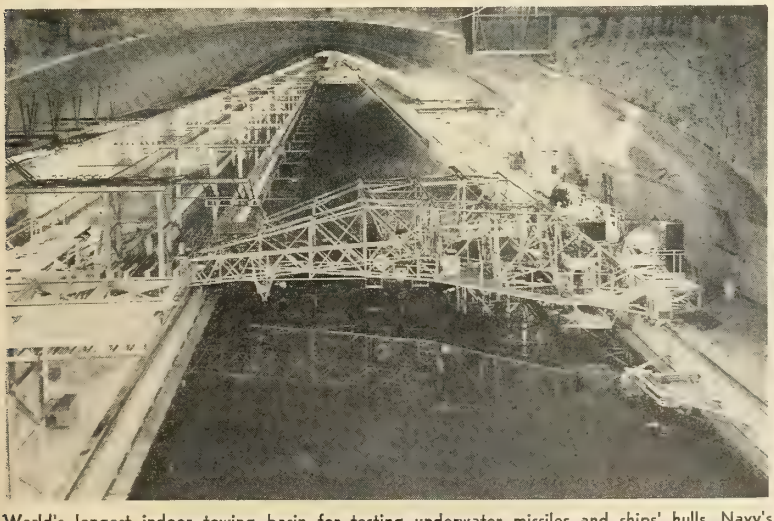
what is believed to be the world's largest tank for the measurement of the underwater sound output of a captive torpedo running under full power.

At the Aerojet-General Corp. in California is another unique facility. Here a tank of water in the shape of a ring is equipped with a rotating arm which can carry a full size torpedo at speeds double those of most torpedoes. In this tank the thrusts of novel propulsion systems, employing high velocity jets, can be measured. When the engineer reports that the torpedo is still putting power into the rotating boom at over one hundred knots, history is being made. This tank is equipped with special wave dampeners to effectively still the water for the torpedo as it hurtles through the ring channel time after time.



To measure speeds and accelerations of free running torpedoes, the Navy has installed in the bottom of Narragansett Bay, R. I., a grid of hydrophones connected by over one hundred miles of underwater cables. These hydrophones, listening to noise made by the running torpedo, feed banks of recorders and computers to provide reliable witness to the performance of the tin fish as it speeds up the range.

The underwater range can plot, second by second, the position of the torpedo to within a few feet during its run. Sound measurements, well into the ultrasonic range, are recorded to be compared with those made in the anechoic tank.



Practical limits are imposed in the design of torpedoes by other considerations than the power plant alone. For example, a running range of 50 miles, with the necessary fuel to go that far, although technically feasible, is operationally unsound. But even assuming a 100 mph torpedo, the time of flight to the target would permit a half hour of evasion on the part of the target ship. Even at shorter ranges, while a 50 mile-per-hour torpedo takes two minutes to go 3000 yards, a 15 knot target can travel 880 yards.

Thus the need points to shorter flight times. This can be achieved in many ways. One obvious means is by increasing the speed, although this has certain limitations. A most significant problem is the horsepower required since this goes up as the cube of the speed. Ultimately, the torpedo could be designed to operate in two mediums —be fired from underwater, emerge and fly most of the way through the air and then return to the water for its final phase of attack.

With atomic submarines a reality, future targets will be capable of much higher sustained speeds. The torpedo of tomorrow is aimed toward defeating the high performance submarine of the future. ★

Tangential-flow turbine is only slightly affected by windage losses at high back pressures. This is type of turbine used with combustor.

World's longest indoor towing basin for testing underwater missiles and ships' hulls, Navy's David Taylor Model Basin has an uninterrupted run of over 3,000 feet and towing speeds up to 60 knots (69.1 mph). So close is test control, two car rails are adjusted to earth's curvature.

High performance (work output per unit weight and unit volume of reactants).

Minimum insoluble products of combustion to cut wake.

Low freezing point, for a wide range of operating conditions.

Low vapor pressure, to simplify storage, transport, pumping.

Low toxicity, for ease and safety in handling.

Ready availability and ease of preparation.

Non-corrosive materials and products of combustion.

Shock insensitive under external shock, high temperatures.

Simple and positive ignition with short ignition delay time.

Primary requirements to be considered in the selection of propellants for modern torpedoes.

Underwater Missile Auxiliary Power Units

By William L. Burriss
and Matthew J. Pastell
AiResearch Manufacturing Company

Woosh! Out of the deep blue sea . . . Amazing German submarine rocket experiment was in the mill at end of World War II, but German admiralty refused to develop the system since it was conceived and demonstrated by the Army...

THE GUIDANCE and control of missiles can only be effected through the use of internal power, usually electrical and hydraulic. In most instances this power is not available from the main propulsion engine. It is necessary, therefore, that an auxiliary or secondary power source be provided within the missile.

The use of static power supplies, batteries and precharged hydraulic-pneumatic accumulators has been effective in early operational missiles because such power packages are particularly advantageous for small loads of short duration. However, similar components for increased loads and longer duty cycles of missiles in development and still "on the board," in general, would be excessively large and heavy. Under these conditions, the utilization of "dynamic" energy sources, i.e., a propellant gas-operated prime mover driving a hydraulic pump and electric generator, could effect large savings in space and weight.

Considerable experience has been gained by the missile industry in the use of propellant gas turbines for auxiliary power. Although analysis indicates other prime movers such as displacement type machines to be feasible (perhaps even advantageous), there is little experience in their application.

The most common requirement for an auxiliary power unit (APU) is to provide a-c electrical power. When direct current is required, in almost every case rectification of high frequency a-c power will show a considerable advantage over the use of d-c generators.

The total power level does little to affect the complexity of the unit, but the quality and variations in electrical output are primary considerations in establishing the complexity and reliability of the complete system. Close frequency control over a considerable load range requires a complex speed control system, and close voltage control requires the addition of voltage regulators.

At present, frequency control can be maintained within ± 3 per cent over a 0 to 100 per cent load range, ± 2 per cent over 75 to 100 per cent load range, ± 2 per cent over 50 per cent to 100 per cent load range, and ± 1 per cent at constant load with a fairly simple and reliable speed control. With a more complex system, frequency regulation to within ± 0.20 per cent can be maintained over any desired load range.

Over small electrical load ranges, permanent magnet alternators offer advantages in simplicity and light weight and have sufficient inherent voltage regulation for many applications. Since the output voltage of the conventional permanent magnet machine is not controlled, it will vary in direct proportion to the alternator speed; therefore, the over-all variation in output voltage is the sum of the frequency variation plus the alternator voltage "droop" over the desired load range.

In addition, these are sensitive to power factor so that variation in power factor also increases the over-all voltage range. When the electrical load variation exceeds 70 to 100 per cent, additional alternator mass is required to provide sufficient inherent regulation for proper over-all voltage control (± 5 per cent) or else some type of regulator must be employed.

Present trends in missile accessory power units indicate that voltage regulation is generally more critical than frequency regulation and that when electrohydraulic output is required, very large changes in load can be expected. These trends favor the use of alternators with a controllable electromagnetic field which can be adjusted automatically to eliminate the effect of frequency on output voltage and compensate for the normal voltage "droop" when changes in electrical load occur.

A flux-switch alternator with a combination permanent magnet and electromagnetic excitation with the latter supplied by load-current sensing transformers provides good voltage regulation.

Duty cycle and alternator frequency are primary considerations in sizing an alternator for power supply use. High frequency (800 to 10,000 cps) allows high rotational speed with attendant reductions in size and weight. The duty cycle will determine the thermal capacity required of the alternator to avoid overheating, and as a consequence, the weight of materials in the alternator.

External cooling with fuel or by other means can either considerably increase the operating duty cycle or generally reduce the alternator weight for a given duty cycle. An example of how high frequency and short duty cycle (uncooled) can reduce alternator size is a 3-kw, 4800-cps, 48,000-rpm alternator weighing 3 pounds.

On units requiring hydraulic power, the hydraulic system demand is usually such as to require steady-state power at a low level and transient power at a considerably higher level. In selecting the hydraulic components which will best meet the requirements, various hydraulic pump and accumulator combinations must be reviewed to see which combination results in minimum system volume and weight.

The first step in the review is to translate the hydraulic requirements to total volume of hydraulic fluid required as a function of flight time. By comparing the requirements with various hydraulic pump capacities, it is possible to determine the accumulator volume required for any given pump capacity.

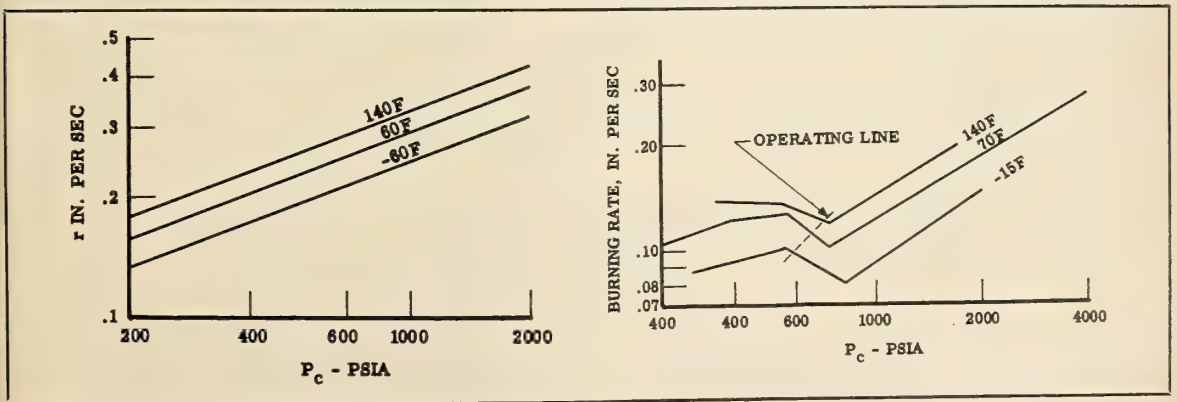
The accumulator volume is then plotted as a function of pump capacity. Since the pump capacity determines, to a large extent, the power level of the system, it is also possible to establish propellant volume as a function of pump capacity. By combining accumulator, reservoir, propellant and pump volumes, it is possible to prepare an optimization curve of total hydraulic system volume as a function of pump capacity.

Using this optimization curve and considering secondary effects such as pump heat rejection, control system complexity, and packaging restrictions, a pump-accumulator combination is selected to provide the smallest practicable hydraulic system.

Speed control can in general be achieved by two methods: (1) by the application of external parasitic loads; and (2) by controlling the flow of the turbine working fluid, either as raw fuel or as hot exhaust gases.

Each of the general methods can be applied in either of two ways:

1. Discontinuous—When speed control is being maintained in this fashion, the parasitic load is applied or the working fluid shut off only when the upper speed limit is approached. When the unit has decelerated to the lower permissible speed, the load is removed or flow of the working fluid is initiated. The step-load change characteristic of this method has sometimes led to its being called a "bang-bang" control scheme. Present ethylene oxide auxiliary power units provide speed regulation to about ±2.5 per cent using a "bang-bang" fuel flow control, and solid propellant units have been built to about ±1 per cent.



2. Proportional—When speed is controlled in this way, the parasitic load is applied in proportion to speed or the working fluid flow is varied in inverse proportion to speed. Using proportional fuel flow regulation and sophisticated electronic controls, steady-state accuracy to ±0.2 per cent can be attained.

The applicability of a control scheme is dependent upon the type of load changes imposed upon the over-all power unit. Step-load changes, like those encountered when a hydraulic power unit incorporates a hydraulic pump unloading valve, makes close-speed control more difficult and usually requires increasing the complexity of the system.

The ideal isentropic power derived from any turbine can be expressed as $HP_i = W\triangle H$

Where HP_i = ideal power input
W = weight flow of working fluid through the turbine
$\triangle H$ = enthalpy drop per pound of working fluid

Of course, the ideal power is not realized as the result of leakage losses, aerodynamic nozzle and blocking losses, and shaft losses. The shaft losses for a full-admission turbine include bearing losses and disk friction and windage losses. The disc windage losses as shown by References (a) and (b) may be expressed by the following approximate relationship:

Mesa type discontinuity exhibited by doublebase propellants tends to minimize dependence of burning rate on pressure.

$$HP_{df} = K_1 p D^2 V^3$$

where HPdf = disc friction power loss
K_1 = proportionality constant determined by turbine rotor design and clearances
p = fluid mass density
D = rotor diameter
V = rotor peripheral velocity

Since the propellant gas turbines designed for missile auxiliary power unit applications are characterized by relatively low power output (1 to 70 shp), they are usually partial admission machines. Of the major losses that occur, the leakage losses are approximately proportional to the degree of admission, while the windage losses are relatively independent of the degree of admission. For this reason, in order to evaluate turbine performance in an application wherein significant windage losses are expected (as result from the exhaust back pressure in an underwater missile), it is appropriate to define the turbine over-all efficiency as follows:

$$\eta_o = \eta_{ad} \frac{HP_s}{HP_s + HP_{df}}$$

where η_o = over-all turbine efficiency
η_{ad} = turbine adiabatic efficiency
HP_s = shaft power output
HP_{df} = disc friction power loss

Further, it can be seen that the turbine adiabatic efficiency can be expressed as a function of the turbine velocity ratio, U/C (ratio of the effective rotor tip speed to the spouting velocity), shown by Reference (c) to be as follows:

$$\eta_{ad} = K_2 \frac{U}{C} (\text{Cos} \propto - U/C)$$

where K_2 = constant of proportionality determined by turbine design
U = effective rotor tip speed
C = spouting velocity of the working fluid
$\propto$ = absolute gas inlet (to turbine) angle

It can be seen, therefore, that the over-all turbine efficiency may be expressed

$$\eta_o = K_2 \frac{U}{2C} (\text{Cos} \propto - U/C) \frac{HP_s}{HP_s + K_1 P D^2 U^3}$$

This indicates that, while the adiabatic efficiency increases linearly with the turbine tip speed, the windage losses increase as the cube. It further indicates that some sacrifice in the adiabatic efficiency is necessary for optimum over-all performance. For example, a 4.0-inch diameter turbine rotor rotating at 50,000 rpm will have disc friction losses of approximately 1 horsepower at sea level (14.7 psia turbine discharge pressure).

In an underwater missile application at 1000 feet depth with a turbine exhaust pressure of approximately 500 psia, the disc friction losses for the same turbine would be about 30 horsepower.

When compared to the APU output of a nominal 10 hp this leads to an over-all efficiency of one-fourth the adiabatic efficiency. It is clear then that reasonable efficiencies will be difficult to achieve on small output units with a conventional turbine.

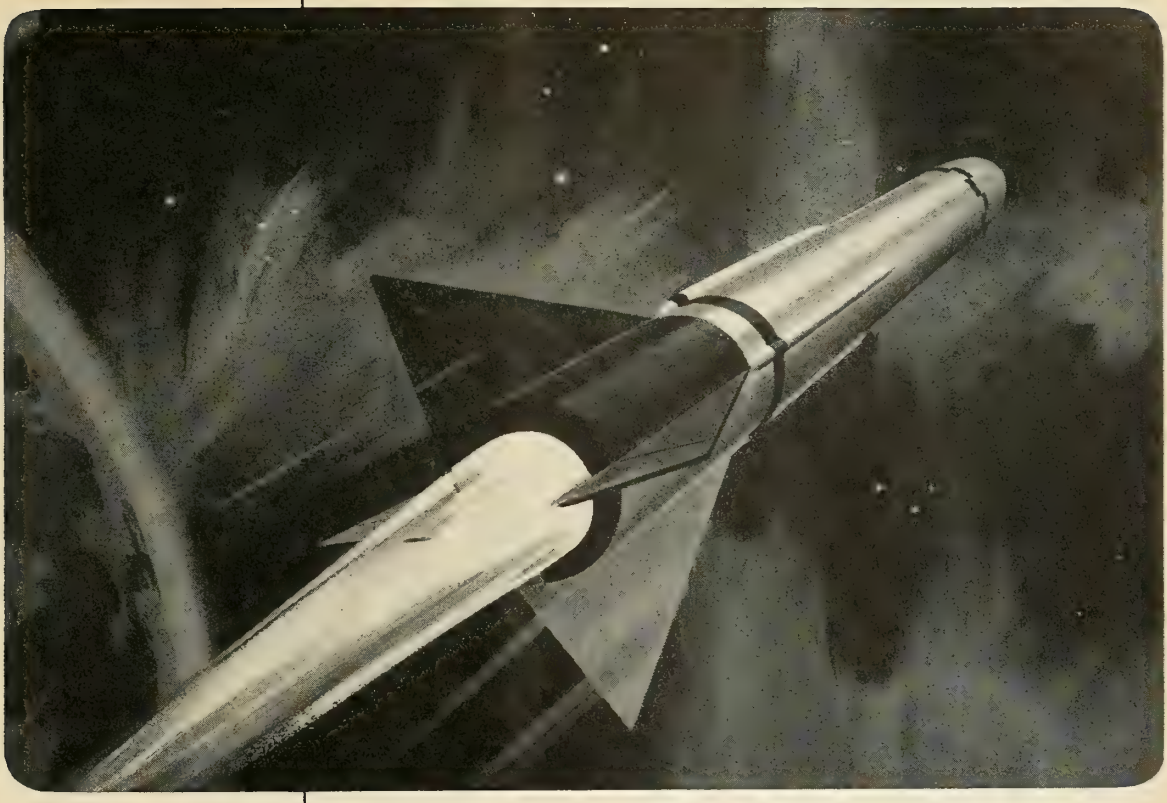
Use of a drag turbine or a displacement type machine is indicated for low output (under 50 hp) applications. A drag turbine offers an advantage in such applications since reasonable efficiencies are obtained at very low velocity ratios. This permits use of low shaft and tip speeds where disc friction losses will be low and also offers the possibility of providing direct drive of a generator and hydraulic pump without the conventional gearbox. Analysis also indicates that relatively high efficiencies, in the range of twenty-five to forty per cent, can be obtained from displacement machines operated off propellant gases. However, the displacement machines will find restricted applications until more experience is gained in their use.

The turbine working fluid of an auxiliary power unit is usually the hot decomposition or combustion products of a propellant. Some very small, short duration power units have used high-pressure stored gas, but because of the very low energy content of cold as compared to hot gas, it is seldom employed and is not discussed here.

Solid Propellant and Liquid Monopropellant

The solid propellants offer two great advantages, simplicity and compactness. However, because of the relatively high burning rates of existing solid propellants, and the fact that the entire fuel tank must be stressed for high temperature—high-pressure operation, their use has been limited to units of relatively short duration. Also, once combustion of a solid propellant is initiated, it cannot be readily controlled by external means, so it cannot be started, completely stopped, and restarted as is required by some irregular duty cycles. Solid propellants are essentially constant energy devices which cannot be metered for operation at part load.

The liquid monopropellants allow considerable flexibility in packaging since the required fuel volume conceivably can be contained in a tank of practically any shape. They also have the advantage of being able to be started and stopped as required by controlling fuel flow to the gas generator. The primary disadvantages of the liquid monopropellant system are its relatively high dead weight (for short duration units) and its complexity.



The effects on selection of a propellant for an underwater missile application are threefold: (1) the generator pressures are much higher, (2) hygroscopic propellants are undesirable, and (3) the ambient temperatures are less severe.

Higher pressures require heavier gas generators to maintain safe stress levels. While liquid monopropellant performance is relatively unaffected, the solid propellants are greatly affected. Both composite and double-base solid propellants increase burning rates as the generator pressure increases.

This phenomenon necessitates the use of longer grains than would be required in an air missile for the same duty cycle. Of course, the "mesa" type discontinuity exhibited by double-base propellants tends to minimize this dependence of burning rate on pressure as indicated by Figures 1 and 2.

The hygroscopic properties of certain propellants would be disadvantageous in underwater missile use. The effects are more severe with solid propellants than with liquid monopropellants. Absorption of water by a solid propellant results in erratic ignition and combustion, and ash in the propellant gases.

The effect of ambient temperature, as with hygroscopicity, is more severe on solid propellants than on the monopropellants. Except for such items as the boiling point and the freezing point, liquid monopropellant performance is relatively unaffected. Of course, additional energy is required to initiate decomposition, but the energy difference is not too significant.

Weapons Systems Responsibility

The Jet Propulsion Laboratory is a stable research and development center located north of Pasadena in the foothills of the San Gabriel mountains. Covering an 80 acre area and employing 1700 people, it is close to attractive residential areas.

The Laboratory is staffed by the California Institute of Technology and develops its many projects in basic research under contract with the U.S. Government.

Opportunities open to qualified engineers of U.S. citizenship. Inquiries now invited.

In the development of guided missile systems, the Jet Propulsion Laboratory maintains a complete and broad responsibility. From the earliest conception to production engineering—from research and development in electronics, guidance, aerodynamics, structures and propulsion, through field testing problems and actual troop use, full technical responsibility rests with JPL engineers and scientists.

The Laboratory is not only responsible for the missile system itself, including guidance, propulsion and airframe, but for all ground handling equipment necessary to insure a complete tactical weapons system.

One outstanding product of this type of systems responsibility is the "Corporal," a highly accurate surface-to-surface ballistic missile. This weapon, developed by JPL, and now in production elsewhere, can be found "on active service" wherever needed in the American defense pattern.

A prime attraction for scientists and engineers at JPL is the exceptional opportunity provided for original research afforded by close integration with vital and forward-looking programs. The Laboratory now has important positions open for qualified applicants for such interesting and challenging activities.

DC REFERENCE VOLTAGE THAT'S

CONSTANT!

- ► from −55° to +100°C
- ► thru 10 G's vibration
- ► over 1000 hours continuous operation

Z-Volt Standard*

TUBELESS CONSTANT VOLTAGE SOURCE

- **Replaces VR tubes and chemical cells**
- **For airborne, mobile and laboratory instrumentation**

Designed to provide dependable DC reference voltage wherever specifications demand long-term stability in the presence of environmental extremes. Uses no tubes or moving parts . . . conforms to shock, vibration and acceleration requirements of MIL-E-5272A. Negligible temperature coefficient, plus freedom from hysteresis and switching effects, make it readily applicable to the most critical measurement and control circuits. Weighs less than 3 ounces; requires less than 1.8 watts. Other features:

- **Small size:** 1 1/16" x 1 3/16" dia.
- **Life expectancy:** more than 10,000 hours
- **Base:** miniature 7-pin
- **Case:** hermetically sealed
- **Random drift:** less than 0.1% over 1000 hrs.

Models to meet wide range of application requirements: Inputs from 26.5V DC or 115V AC, 60 or 400 cycles. DC output 6.2V at 1 ma or 10 ma, 1V at 1 ma. Modified types can be developed to meet your particular needs. For complete specifications and performance data, write for Bulletin (MR-5), Avien, Inc., 58-15 Northern Blvd., Woodside 77, N. Y.

Propulsion Notes

By Alfred J. Zaehringer

Big push is now for expansion in LOX generating and transportation equipment to power our new line of ballistic missiles (all using LOX). Office of Defense Mobilization and the Business & Defense Services Administration now offer fast tax write-offs if producers can turn out LOX and nitrogen of at least 99.5% purity. Other conditions: LOX-nitrogen production ratio must be 4—1 and delivery to military customers must be assured. Latest new LOX plant will be a $9 million unit at Acton, Mass. for Air Reduction. Overall, the firm is expanding oxygen facilities by at least $20 million. Linde is to expand its oxygen facility at Ashtabula, Ohio by $12 million with similar boosts at East Chicago and Kittaning, Pa.

Improvement of the standard dewar flask—used for storing LOX and other liquefied gases—has been reported at Bureau of Standards, Cryogenic Engineering Laboratory, at Boulder, Colo. Evacuated powders such as diatomaceous earth, perlite, and silica aerogel have been used.

First tank-car shipments of Westvaco Dimazine were recently made by Food Machinery from its S. Charleston, W. Va. plant. The fuel, dimethylhydrazine, now goes into the *Nike* and other new missiles.

Improved physicals in hypergolic white fuming nitric acid systems is claimed in a new patent granted the California Research Corp. The firm found that addition of 4% sodium nitrite to a 96% WFNA-4% water solution lowered the freezing point to —97°F. In addition, a similar mixture could be stored at 122°F for 48 hours without gas evolution. It is claimed that the mixture does not greatly increase the ignition delay in most hypergolic systems.

Relation of chemical structure and "hypergolicity" of amine fuels has been suggested by RMI. For best hypergolic operation, the rules are: have one C-H bond at the alpha-C in an aliphatic primary amine; use a methyl group in place of a secondary H atom; don't use a methyl group for a secondary H further away from the N than the alpha-C; use amine, hydroxyl, or phenyl groups on the beta-C; alkyl in primary saturated aliphatic amine should be myl; in secondaries it is outyl; in tertiaries it is propyl. With the same number of carbons, tertiary amines are best, next come secondary and are followed by the primaries.

New partnership on the horizon: Gulf Oil Co. and Mine Safety Appliances Co. (a subsidiary of Callery Chemical) will cooperate on joint efforts in the field of high energy fuels and boron chemistry.

Standard Oil Co. (Ind.) has a new hypergolic fuel for use with nitric acid. The liquid is made by pyrolysis of hydrocarbons from butane, butylene, ethane, gas oils, naphtha, propane, and propylene. For hypergolic operation, the acid content has to be at least 95%.

In experiments with a hydrogen-fluorine torch, Temple University researchers have hit a maximum flame temperature of about 4300 K. Composition was 54% hydrogen and 46% fluorine.

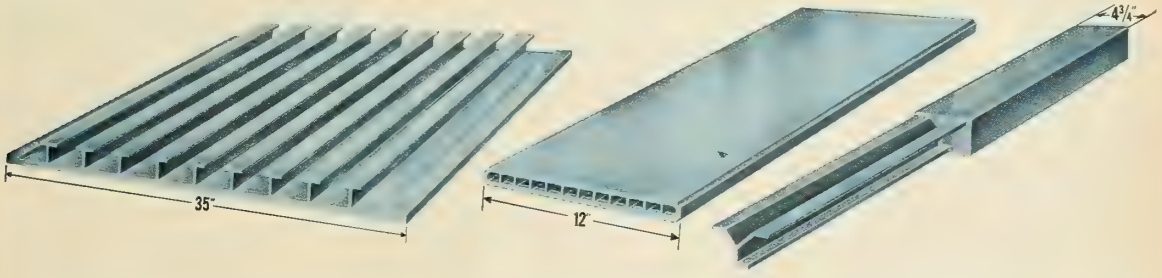
French experimenters are using a turbo-reactor to study the combustion of hydrocarbons with an eye to understanding the combustion of kerosene. Work sponsored by the Ministry of Air under Rappeneau and Roy is turning up laminar and turbulent flame speeds, flame temperatures, and vaporization data. Another work by the same agency has concluded that in the combustion of substituted pyridines, this compound has a high anti-detonating power which is probably a result of its strong anti-peroxide formation reactions.

New stabilizer for nitrocellulose propellants has been disclosed by Hercules Powder. Some 0.2—2% of the substituted diphenylamines, urea, or dicyandiamide and 0.02—1% of citric, phosphoric, or stearic acid is blended with a nitrated cellulose to form a product of 13.1—13.2% nitrogen.

New Design Trends for

Harvey Aluminum Extrusions

To any experienced engineer or designer, aluminum extrusions are a common commodity. You don't have to tell him that extrusions offer such advantages as ease of fabrication, design flexibility, etc. He knows that. What he wants to know now are the newest advances made possible by the extrusion process.



Potential for new configurations and applications

Typical new applications for Harvey Aluminum Extrusions are illustrated below. The design possibilities for aluminum extrusions are now practically limitless. Large heavy press sections; unusually complex shapes; wide, integrally stiffened skin panels; solid, hollow, and stepped extrusions; and extra long thin sections can be obtained from Harvey in all aluminum alloys. Heat-treated shapes can be produced in lengths up to 80 feet, weighing as much as 2,500 pounds. The maximum circumscribing circle diameter practical is 25½ inches. For functional, structural, or decorative applications demanding custom design plus light weight, corrosion resistance, high strength, and a naturally attractive finish, Harvey Aluminum Extrusions are first choice. And remember, Harvey is traditional for high quality and service.

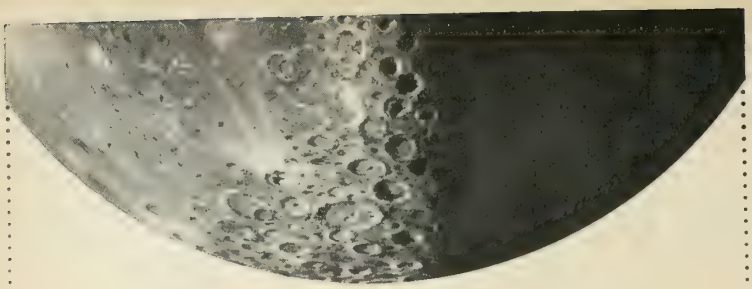
Harvey Aluminum leads in extrusions

Harvey's completely integrated facilities include a large complement of extrusion presses ranging in size from 1400 tons to 12,000 tons, stretch-straighteners up to 3,000,000 pounds capacity for lengths up to 105 feet, and the newest supporting and finishing equipment.

If you have a problem with extrusions, thoroughly qualified Harvey specialists are always ready to help you improve your product. Write to Harvey Aluminum Sales, Inc., Torrance, California, or contact the nearest sales office listed under "Aluminum" in your classified telephone directory.

INTEGRALLY STIFFENED SKIN PANEL is produced in extra wide widths on heavy presses. Combination of skin and stiffeners in large panels minimizes machining, simplifies assembly, improves performance of aircraft, missiles, and military vehicles.

DECK COOLING PANEL for aircraft carrier is extruded on heavy presses. Light-weight, water-tight aluminum panels circulate water to offset intense heat generated against deck in jet aircraft operations.



STEPPED EXTRUSION for aircraft structural member eliminates machining and reduces assembly time. Aluminum part is lighter and stronger than outmoded built-up section formerly used.

Making the most of aluminum . . . for everyone

HARVEY ALUMINUM SALES INC., TORRANCE, CALIFORNIA

HARVEY Aluminum

Harvey is a leading independent producer of quality aluminum products in all alloys and sizes: Rod and bar, pipe, tube, hollow sections, press forgings, forging stock, impact extrusions, structurals, special shapes, extrusions, screw machine products and other aluminum products. Harvey is also producing similar items in titanium and steel.

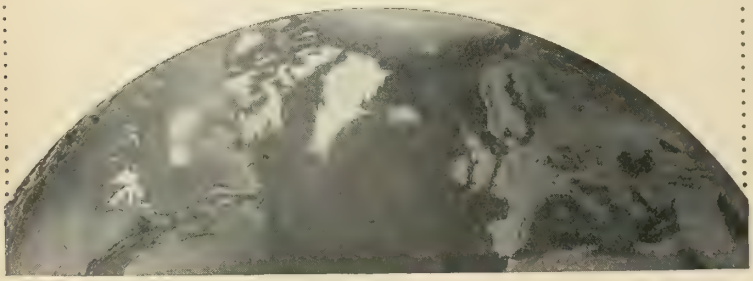
Men who know

TURBINES, PUMPS, COMPRESSORS

Get in on the development of the most advanced high-speed rotary equipment ever built

Here's your opportunity to step up to a new, higher level of turbo-machinery technology—the Large Rocket Engine.

Whatever type of rotating machinery you know best, your experience could be extremely valuable in the important developments now going on at Rocketdyne. The seasoned and ambitious man who has cut his teeth on jet engines, steam or gas turbines, or other elements of rotating machinery, is urgently needed to apply mechanical principles to meet the increasing demands of power plant performance.



The combination of high speed, light weight, heavy loadings and exceptional pressures required in rocket engine work is leading to an entirely new breed of high-performance rotating machinery... and a new breed of engineer. You can be one of this advance guard of the turbo-machinery field—if you have the desire to build your professional status by accepting new challenges.

Rocketdyne is building high-thrust rocket engines for the nation's major missiles. You'll work with the leading producer in the nation's fastest growing industry. You and your work will be recognized as a vital part of the overall achievements. Testing facilities are among the world's finest. The power produced is beyond anything ever before thought possible. If you would like to tackle new assignments working alongside some of the finest minds in turbo-engineering, write and tell us about your background: A. W. Jamieson, Rocketdyne Engineering Personnel Dept. MAR-51, 6633 Canoga Avenue, Canoga Park, California.

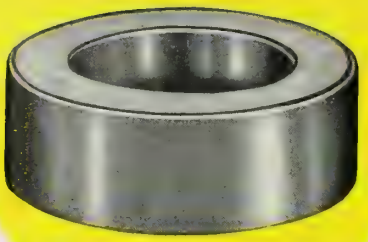
Loewy Contract For *Polaris*

The Loewy-Hydropress Division of the Baldwin-Lima-Hamilton Corp., New York City, has been awarded a contract by the Navy for design and construction of a full-scale ship-motion simulator for testing the Fleet Ballistic

POLARIS ship motion simulator.

Missile, *Polaris*. The device will be installed at Patrick Air Force Base in Florida.



Ship motions will be reproduced from magnetic tape recordings taken at sea. The unit will be capable of conducting actual test firings.

Magnesium Extruder For Missile Output

The Dow Chemical Co. announces completion of a 13,200-ton extrusion press, the largest in the world for extruding magnesium, the second largest for non-ferrous metals. It is expected to be especially useful in the production of round hollow tubing for missile bodies. It is able to produce integrally stiffened sections from nine to 20 inches wide; I beams from 11 to 28

Reaching for a Star...
Photon powered interplanetary craft
Speed: 186,000 Miles Per Second
Travel Time to Nearest Star: 3.6 years
Man's most elaborate thoughts on interplanetary travel now involve a photon powered craft whose speed would be that of light, 186,000 miles per second. This would make travel time to the nearest star, Alpha Centauri, about three and one half years.
When a light propelled craft comes into being, we believe that Western Gear will be actively and intimately involved, just as it is today, participating in major projects, designing and building automatic or semi-automatic aircraft gear drives, control systems and rotary electrical equipment.
While our eyes are on the future progress of aviation, our engineering and manufacturing talents are occupied today in solving the myriad control problems of the industry. For thorough reliability and the RIGHT design, why not call a Western Gear Application Engineer now? Write, wire or telephone Western Gear Corporation, General Offices, P. O. Box 182, Lynwood, Calif.

inches high; round tubing from a 10-inch to 24-inch outside diameter. It boasts a 3000-ton piercer for optimum simplicity in producing hollow extrusions.

Diversey Builds New Missile Plant

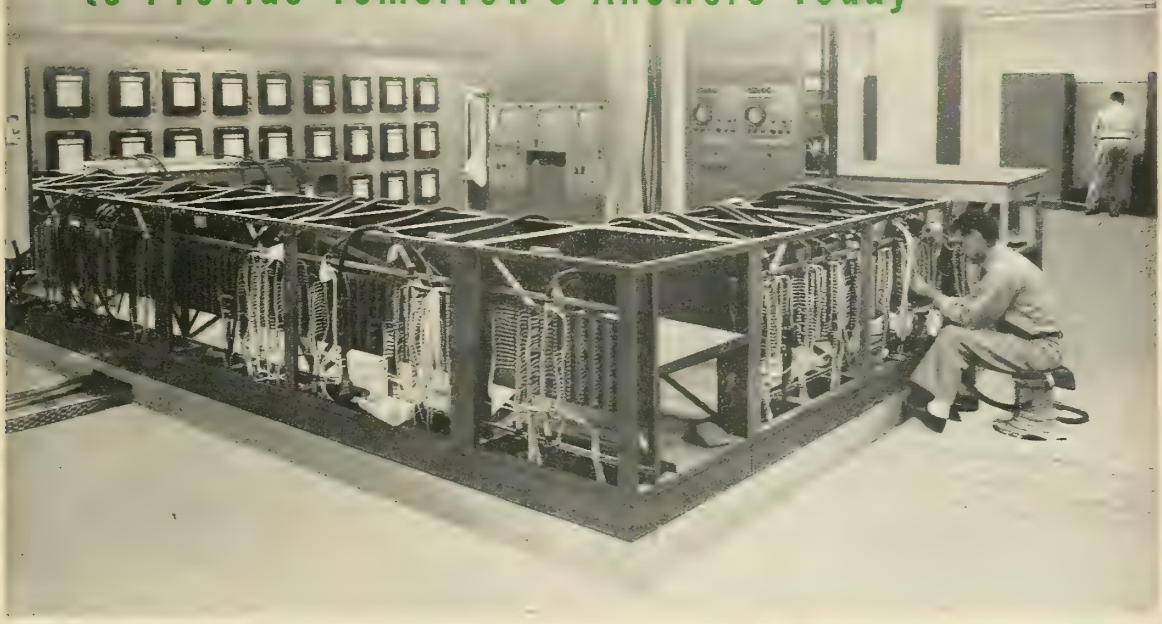
Diversey Engineering Co. president J. H. Kauffmann has announced construction of a new $250,000, 31,000 square feet plant at Franklin Park, Ill. Planned especially for missile work, it will have the most modern contour milling equipment, largest Monarch Air Gage tracer lathes and will be equipped to work on titanium, inconel, A-286, Haynes stellite and zirconium.

Colloidal Graphite Used In Satellite Construction

Colloidal graphite suspensions, supplied by the Acheson Colloids Co., Port Huron, Mich., are used as a lubricant and parting agent during the deep-drawing and spinning of the satellite's magnesium sphere. After the naptha carrier has evaporated and left a tough thin graphite film on the magnesium, the sheet is preheated to 600-650°F. The prelubricated hot sheet is then deep-drawn into a hemispheric shape by a 750-ton hydraulic press.

Brooks Perkins, Inc., manufacturer of the spheres, says "ten to fifteen or more" are to be built for testing and actual firing.

Cambridge Reveals New LOX Facility



Cambridge Corp., Lowell, Mass., has revealed details of its new liquid oxygen loop project R-1, the first commercially available facility of its kind in the U.S. The liquid oxygen cold flow test facility is available to private industry for testing performance and reliability of rocket and missile equipment in the cryogenic field.

Army Engineers' A-Plant Is Air Transportable

Last month the public was given its first look at the Army's prototype package power reactor, designed to be air transportable to advanced bases, such as, for example, missile launching bases. Designed by the Atomic Energy Commission and built by Alco Products Inc., Schenectady, N. Y., the first APPR (Army Package Power Reactor) will be used primarily for test and development. Its rated output is 1855 kilowatts.

Submariner "Swede" Momsen

On undersea warfare, 60-knot submarines, high-speed underwater guided missiles and hydrodynamic boundry layer control

Naval Academy graduate Vice Admiral Charles B. Momsen, USN (Ret.), is Mr. Submarine. Developer of the famous Momsen escape lung, he has pioneered undersea warfare since just after World War I. Now retired, he is anything but inactive but, as a fast traveling consultant to industry, leads the nation's thinking on the eve of the submarine's greatest era of development—peaceful and military.

Q. *Admiral Momsen, will you tell us how the strategic role of the submarine compares past, present, and future?*

A. In referring to the past, I'll take World War II. Then the submarine was handicapped. It was slow and was restricted in its ability to stay submerged. It was referred to as a weapon of opportunity because it had to be pretty much in the path of the target it was seeking to attack.

Q. *What were the underwater speeds?*

A. In the beginning of World War II, the maximum submerged speed was nine knots, and if the submarine ran at nine knots it would only run for about one hour before it ran its batteries down. Its top surface speed was 18 knots. German submarines started out with about the same speed characteristics, but they improved their underwater propulsion system by using thin plate batteries with greater capacity. Toward the end of the war they had one submarine which we believed could make 26 knots.

Q. *Was that with the hydrogen peroxide motor?*

A. Yes. That was the Walther cycle, and hydrogen peroxide with diesel engines. That submarine didn't actually get into the war but it was the forerunner for some work that we've done. They built one working prototype. It was undergoing tests when the War ended.

Q. *Wouldn't the Russians know that design?*

A. Oh, yes.

Q. *The Russian submarines are supposed to be based on the German Type XXI long range design, aren't they?*

A. Yes.

Q. *What can you say about the type XXI's range?*

A. Well, when we refer to long range submarines we refer to those capable of operating 5,000 miles away from the bases. A great many of the Russian submarines listed now as you know are quite old, but on the other hand they are building new ones and unfortunately we don't know too much about their characteristics.

Well, we're still talking about the strategic role of the submarine which at present is undergoing an evolution. We're getting now to higher speeds and greater submerged endurance, but no one has a complete fleet of that type of submarine as yet. We can't say that the present is changed much from World War II, but the future holds a great deal of change. I think the future submarine will have mechanical endurance that's practically unlimited. It will have speed capabilities as high as 60 knots underwater. You can never make it on the surface. A submarine inherently will be able to make more speed submerged than on the surface. The reason for that is that a submarine completely submerged and two or three diameters below the surface is freed of wave making losses.

Q. *Can you speculate on future under-sea warfare?*

A. Yes. With the high speeds which will be available to submarines, they will pass from the category of the weapon of opportunity to a weapon which creates its own opportunity, and of course the strategic role will be very much improved because they can get to more places on more assignments and possess a much greater technical capability when they get there. An animal confined to the surface of the water is limited in its tactics to two dimensions of travel. The birds and fish who operate in three dimensions have an inherent tactical advantage. Therefore, I believe that when the submarine is fully developed, or as

Future submarines . . . will do 60 knots.

In three dimensions . . . an advantage.

Fish have nerve ends in their skin.

fully developed as the aircraft, surface ships will not be able to protect themselves. It follows that in the not too distant future control of the sea may well be by submarines and aircraft. I feel that this is coming.

I think you will remember that toward the end of World War II, the Germans had prepared a V-2 or V-3, I think perhaps a V-3 missile, in a container which was to be towed behind the submarine to our coast off New York City.

It all points to the fact that the submarine had that capability. At the present time, as you see, we're bringing our submarines up to the surface and launching from the deck, but I feel that eventually we'll be able to launch missiles through tubes and they will be either torpedoes which operate entirely in the water, or will come to the surface and become airborne for various purposes, intercepting surface ships or aircraft through the use of radar.

Q. *Will 60 knots for the submarine be faster than, say World War II torpedoes?*

A. Much faster. The fastest torpedoes that we knew of were around 45 knots, but that was fast enough for the target which they were seeking in World War II. I believe that no matter how high the submarine speed will get we'll always be able to make a torpedo go faster, simply because the torpedo doesn't have personnel in it.

Q. *What was the outside range of the torpedo that we used during World War II?*

A. Approximately 10,000 yards.

Q. *Does this apply to the straight run torpedo or sonar guided for both?*

A. That was a straight run and fairly slow speed, about 30 knots. Our torpedoes had two speeds, high speed for short range and low speed for longer range.

Q. *Am I correct in assuming that the reason for emphasizing the quietness in torpedo propulsion is that you don't jam your own homing devices that way?*

A. For a homing weapon there is always a battle between the self noise and the noise of the target, and the weapon has to be quieter than the target by quite a margin because it's listening to a target at some distance away. But, submarines versus submarines is much like Indian warfare. One has the advantage of not being committed to move. He can lay quietly in one place. The other one has an objective to go through, and to accomplish this he must move. This makes a certain amount of noise.

Q. *Sonar has been the primary basis for torpedo guidance. Are there any other methods that might be used?*

A. Well, in general electro-magnetic waves do not penetrate the sea and therefore, one way or another we have to rely on sound for the exchange of intelligence whether it's a torpedo or a communications system.

Q. *Isn't there a sound refraction problem in the ocean that can get quite severe?*

A. It is a very difficult problem. What actually refracts sound is the change in density. The speed of sound is a function of the density, and the greater the density the higher the speed of sound.

Q. *What effect does this have on homing torpedoes?*

A. An acoustic torpedo is always aiming at the noise source. It may be a long way around but eventually it arrives at its target.

Q. *We understand that the fish are not concerned with such things as cavitation, that flight, often at high speeds, is remarkably silent. Do you feel that performance of man-made water vehicles might be improved through careful study and emulation of fish design?*

A. I would think so. We have no known hydrophone that can record the noise of a fish traveling through the water.

Some fish hit speeds of around 50 knots, and they're highly maneuverable. The porpoise is fairly fast; the barracuda is very fast. But I don't think we really know how fast they can go because very fast fish rarely have the urge to go at their top speed.

Q. *They never cavitate?*

A. Never, unless they are very close to the surface. Cavitation is a function of pressure, and if they get very close to the surface, well, then they get less water pressure around them and are apt to cavitate. But I have seen barracuda come right up to the window of a diving bell at very high speeds, stop suddenly with not the slightest sign of cavitation, no noise and look at you for a few seconds and then like a flash he's gone again and still no sign of cavitation. I've done some work with the Coleman Engineering Co., in Los Angeles on the matter of hull cavitation and the reduction in drag. Dr. Max Kramer, a German scientist working with them, has been studying this subject for quite a while, and we believe that he has solved the riddle as to what causes cavitation and how to prevent it and promises a very substantial reduction in drag.

That work is a private venture and is not being supported by any of the military. Very often we get very fine things from private projects.

Q. *Can you say anything concerning when the prototype with a 60 knot sub might be launched?*

A. I haven't the slightest idea. I notice that about two weeks ago in the *New York Times* there was a very small article that said the British were developing a very high-speed submarine. It's feasible, it's coming. There's no question about it's coming. The question is whether the effort will be put into it.

Q. *Effort means dollars?*

A. Well, that's right, hard rocks. Dollars, and there

If flow is laminar . . . noise is reduced.

Torpedoes . . . will become airborne.

The sea is still a place to hide.

are some technical developments, too, that we think are feasible. There aren't any problems that can't be solved.

Q. *Does anyone know why fish don't cavitate?*

A. Well, cavitation is caused by unequal pressures along the side of the surface, as it moves through the water.

Q. *Is cavitation equivalent to going from laminar to turbulent flow in the boundary layer?*

A. Exactly the point. The difference between turbulence and laminar flow is the unequal pressures along the surfaces. It's my feeling that the fish has nerve ends in its skin and that unequal pressures are uncomfortable. Through muscular effort he makes minor changes in his shape and keeps the pressures equal and therefore, the flow laminar. And if the flow is always kept laminar you will not have turbulence, and your water noise will be reduced.

Q. *Might you not then, where you tend to cavitate, blow in or suck off water to maintain laminar flow?*

A. That's right. It's the same approach, but in aircraft turbulence results in increased temperatures plus increased drag whereas in the submarine, it's increased drag and increased noise. And, if submarine turbulence can be controlled through the control of the boundary layer it will be applicable to propellers as well.

Q. *Do you personally feel it would be practical to develop a medium range ballistic missile capable of fitting and being fired from the torpedo tubes of submarines now in service?*

A. Not necessarily from current torpedo tubes. We have been locked to a 21-inch tube for many years. The Japanese increased theirs to 24 inches. There's no reason why we shouldn't use 24 inches or even 48 if we had a purpose for it.

Q. *Just to get complex for a moment, do you see any future need for a transitional missile that starts out traveling underwater; then rises to the surface and becomes ballistic; then reenters the water to act like a torpedo again?*

A. That sort of thing might be needed for a restricted submarine, but not the submarine of the future.

Q. *Well, suppose we had an underwater distant early warning system—a network of sonar buoys spotted around our coasts. We wouldn't need as many anti-sub submarines on patrol. A submarine off New York equipped with such a missile could attack an enemy submarine off Cape Cod.*

A. Then it wouldn't have to travel underwater first, except to float to a safe vertical firing position. Only two stages would be required. That is something that is under consideration. There's no need for three stages. I'd like to suggest also that such a sonar buoy network would be readily subject to destruction by the enemy.

Q. *Would this be true of passive devices?*

A. In the defense against future submarines, if they're going to be as quiet as I think they will, there will have to be more than just passive sonar. An active system could be traced by its own signals.

Q. *What was the range of passive sonar in 1945?*

A. By World War II the Germans could hear a large surface ship perhaps 75 or 80 miles away. They could hear convoys with ease at 30 or 40 miles.

Q. *Can we assume this has been improved?*

A. Yes. We can hear depth charges, for instance, tremendous distances, several hundred miles.

Q. *Can you get direction and estimate range?*

A. You can get a pretty good direction fix but no range. Underwater sound is a very interesting subject because we have in the past been thinking only in terms of the spectrum of sound that the human ear can hear. We haven't investigated the very low frequencies or the high frequencies beyond the oral range. There is a principle that we'll have to keep in mind that the higher the frequency, the greater the attenuation of the sound in water. In other words, very high frequency can be heard at only very limited ranges, where very low frequencies travel perhaps thousands of miles. That is the nature of sound in water.

Q. *What are the limitations of underwater warfare?*

A. Well, there are three areas of limitation. One is communication; the second is navigation; and the third is human endurance. Now we've talked quite a lot about underwater communications and so far as we know at the present time sound is the only means of communicating completely underwater. Low frequency radio penetrates the water a little bit, a matter of a few feet. From a navigation standpoint, I think a great deal can be done. Nowhere in the ocean is land more than five miles away vertically. We can put navigational fixes on the bottom just the same as we do navigational beacons for aircraft on land. From the standpoint of human endurance, that is a problem everywhere and in every endeavor of life we have to provide fresh water and air to breathe.

However, if we look again at nature we find fish are able to get oxygen which is in solution in the sea water and have their CO_2 carried off in the sea. This is the same process of the human lungs, except that we expose air to a membrane. Now in the ocean there's much less oxygen in a cubic foot of sea water than there is in a cubic foot of air. Therefore, great quantities must flow over the membrane. If we can ever become as smart as nature why we'll have all three problems solved. It's quite interesting that fish maneuver so well together. You see a school of fish make a radical change of course simultaneously without collision. Fish will spawn in a river and go to sea and disappear hundreds of miles away, maybe thousands, and yet the following year they come back to that same river.

Q. *I would like to ask you whether you think the submarine is the best weapon against another submarine?*

A. I believe that it is. I have been advocating that for some time. I believe that the submarine has inherent advantages over another submarine that nothing else has. Some people in the Navy now say that we shouldn't have submarines that are specifically designed for anti-submarine roles, that all submarines should have those roles. I have never believed in that because I think that if you have a very important mission for any ship or plane, that it ought to be built for that mission.

Q. *What do you see as the peaceful future of underwater development?*

A. That is another area in which I am doing work now, and it's quite interesting. The U.S. Rubber Co. is working on underwater fuel and cargo transport by means of rubber barges. We can make these rubber containers of considerable size. They can be towed by a submarine and I believe that it will be financially or economically feasible to transport fuel, grain and other bulk cargo, cargoes that can withstand the sea pressure. You've got two advantages there. One, less drag under water than on the surface. Two, the bulk of your investment, the tow boat, doesn't have to sit in port for three weeks while they load and unload it. Also, it is free from wave motion and wind and storms. For the return trip this container can be rolled up and carried on the deck of the ship and you don't have to tow an empty ship in ballast on the return trip. You don't need a long tow line because you don't have the motion of the sea to work against and because of the nature of the material, rubber being flexible, you can violate all the laws on length-to-beam ratios that are required on ships. You could make one of these containers 20 ft. in diameter and a mile long if you want to.

Q. *Of course, for military purposes again it would be invaluable.*

A. Yes, safety concealment from attack. The sea is still a place to hide. ★

Rocket Propellants for Underwater Missiles

By Alfred J. Zaehringer

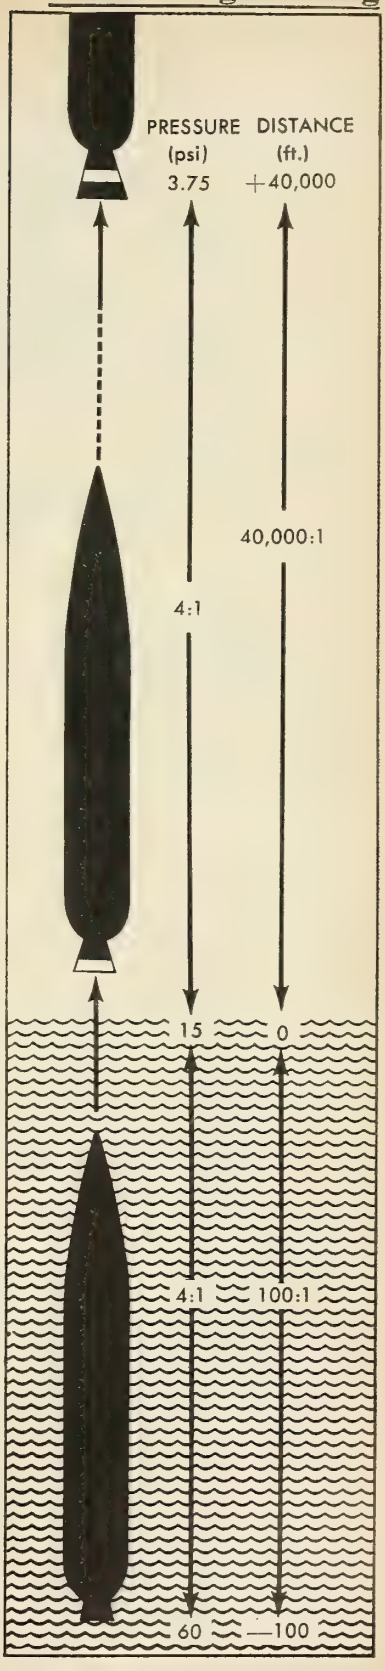
THE ROCKET POWERPLANT now allows the underwater missile spectrum to be expanded to include other subs, ships attempting evasive action, anti-sub patrols, and even distant land targets.

The advent of rocket and nuclear power has given the submarine a new lease on life. Atomic power gives the sub an almost unlimited striking range while rocket power can replace the conventional torpedo or deck gun. The main purpose of the modern sub will thus be to carry out atomic strikes on distant land targets—while remaining conveniently submerged.

Environment (Care)

To the landlubber rocket engineer, two environmental conditions are encountered—pressure and temperature.

The underwater pressure is a product of depth and density. With seawater (density about 64 pounds per cubic foot) about 33 feet of depth raises the pressure one atmosphere. Thus, at a depth of 60 feet, the pressure is about 60 psia.



For optimum expansion the nozzle should expand the combustion gases to ambient pressure. Thus, as the missile rises vertically, the pressure decreases, and the nozzle has to get bigger. Therefore, some optimum expansion point has to be selected.

It is perhaps fortunate that a vertically ascending missile will be under greater than atmospheric pressure for only a short time. However, the difference in thrust (and overall pressure system) must be taken in account.

It is interesting to note that at a depth of only a few feet, water pressure can be helpful, in effect increasing the nozzle length without adding missile weight; this effect, useful in rocket torpedo work, acts to increase the thrust coefficient. Since subs can operate at 200-300 feet, operating normal liquid rocket engines poses some problems:

How do you operate at a chamber pressure of 300 psia when the outside pressure is greater (pressure at 300 feet is about 320 psia)? What is the optimum expansion ratio for rapidly changing pressure? What about variable combustion pressure? Not only are propulsion problems difficult but structures must be beefed up to take the higher external pressures.

How far down would you want to fire an IRBM? For a missile nearly 100 feet long, the depth would have to be 100 feet so that the missile is still submerged. It appears the depth would be 200-300 feet for maximum hiding.

Pressure difference (4:1) to depth of 100 feet is about same as from sea level to 40,000 feet. This calls for increasing nozzle exit area for optimum expansion.

Table 1

PROPULSION SYSTEM PARAMETERS

Type	System	Performance	Hazard	Cost	Storage
Liquid	LOX-Fuel	H	V-L	Low	NP; OB

Possibly one item of consolation—sea temperature could be quite useful. For one thing, the surface temperatures have a narrower fluctuation than on land. The upper limit is 80-85°F in the tropics and seawater freezes at 28-29°F. Thus, the temperature range is only 50-55°F. Within a given season, the variation is less than 10°F and about 1°F between day and night.

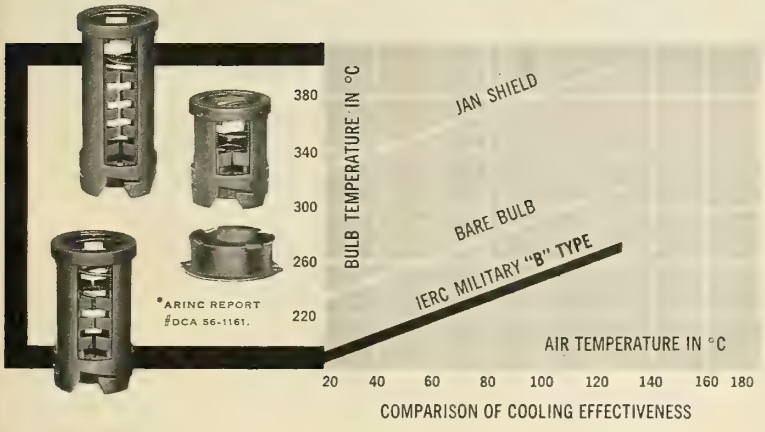
As you go down, the temperature the world over tends to become lower and constant—the average is about 34°F. Thus, we have a gigantic constant temperature bath and an exposed underwater missile will not operate under such wide temperature extremes as experienced by land or air missiles (viz., —80° to 180°F). It is conceivable that if needed heat could be fed to the missile to maintain higher operating temperatures.

In a vertically ascending missile, the effects of waves would have to be considered. When breaking the surface, the missile would not yet be moving fast and would be vulnerable to waves and then the winds.

Since timing might be critical against a land (or air) target, a calm sea can't always be counted upon. A breaking wave on a solid object, for example, can generate pressures of 2,000-14,000 pounds per square foot over a time span of 0.05-0.005 sec.

The variation of wave height with wind speed will certainly be instrumental in determining when to fire—particularly a large ballistic missile.

Other factors, too, are important. For long-range missiles designed to operate entirely underwater (such as anti-ship or sub), guidance and control systems will have to take care of varying currents or shifts in currents. Action of seawater on structures, especially where missiles are immersed for prolonged periods, is also important.



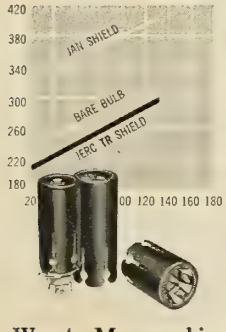
Not only is it a matter of preventing corrosion and barnacle growth but you also have to worry about keeping out water. This is quite different from land or air missiles.

Propulsion (Feeding)

The selection of a propulsion system for an underwater rocket is governed by such factors as performance, storage, hazard, etc. Such parameters are presented in Table 1. Of the liquid propellants, LOX systems are not attractive for ready-to-go storage in missiles for extended periods of time.

However, all liquids offer one large headache for naval service: leakage. In addition, a very high degree of reliability is required and, at the present time, this reliability could best be offered by solid systems. Solids can now give ready-to-go systems which

NOW—increase electron tube life *12 TIMES!



COMPARISON OF COOLING EFFECTIVENESS

Exclusive IERC Tube Cooling Effectiveness Provides Greatly Extended Tube Life And Reliability!

Though electronic engineers know that even the *slightest* tube temperature reduction improves tube life, the greatest success enjoyed in obtaining *extended* tube life has been when IERC Heat-dissipating Tube Shields have been specified and used. Results show that extensive gains in tube life and reliability are easily achieved—that tube operating temperatures are reduced as much as 150°C—that IERC's Military Type "B" shield is the *only effective answer* to obtain these benefits in *your* new equipment. Positive shock and vibration protection plus electrostatic shielding is provided. Graphs show temperature reductions when IERC "B" and "TR" shields are used with 6005 tube operating at full plate dissipation. Meets or exceeds Mil—S—9372B (USAF).

PATENTED OR PATS PEND. CROSS-LICENSED WITH NORTH AMERICAN AVIATION, INC.

Retrofit For Maximum Tube Life

No modification is required with IERC "TR" Type Heat-dissipating tube shields! TR's fit easily to existing JAN sockets—greatly extend tube life through excellent cooling and retention against shock and vibration.

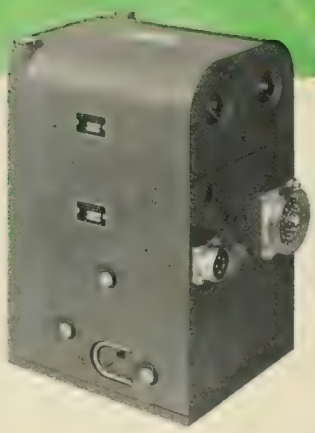
can be stored for over a year with zero maintenance.

Maintenance, however, may not be a strong objection if the sub's prime mission is to launch an IRBM. Of all the liquid systems, the nitric acid propellants can come close to meeting all requirements.

Because of relative insensitivity to low temperature operation, and ability to operate at high pressures (1000-2000 psi), the composite solids would be ideal for underwater use. Other advantages are: grain designs can allow for a programmed thrust (and pressure).

In addition, there are the mesa composites where burning rate is independent of pressure in the 1000-2000 psi range. This is advantageous since the effects of back pressure can be absorbed and the grain geometry can allow for the best mass flow (including a variable mass flow) during a rapidly decreasing sea pressure.

Internal storage systems could be used for smaller missiles (rocket torpedo or flak) of both the liquid and solid variety. Deck pods could be used for large missiles where the sub's crew could be used for servicing the missile.



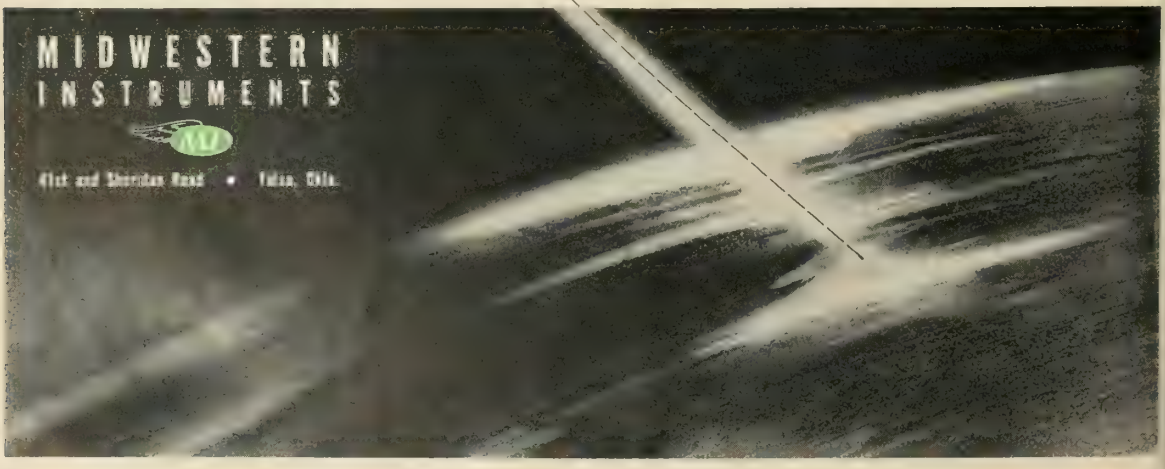
Towed pods would be attractive for very large systems or for the high hazard liquids. Another advantage of a towed pod is that it could be jettisoned on completion of the mission or could be dumped if necessary to save a sub.

It is thus seen that missiles will breathe new life into the submarine. The impact on naval strategic and tactical warfare will be as great as nuclear power. With such subs, the age of the present highly vulnerable aircraft carrier is rapidly coming to an end. The salient features of the missile-sub weapons system are: unlimited range and striking power, relative independence of a vulnerable base, and the very great element of surprise.

Since 1955 the Russians have been completely independent of German brain power, although most of the current missiles reflect the German thinking that conceived them in their early stages of development. There is some evidence that the Russians are still using Peenemünde missile base in East Germany for underwater missile research projects.

All evidence indicates that Russia is now on its own in the missile field and is doing well. Missile enthusiasm abounds among the entire Russian executive class. The apparent attitude of Russia's leaders is to have large quantities of undersea missiles available as quickly as possible. As is the case with most Soviet weapons, the emphasis is on simplicity and reliability.★

engineered to ride a rocket



THE MIDWESTERN 561 RECORDING OSCILLOGRAPH

561 SPECIFICATIONS

Weight	15½ lbs
Dimensions	6-11/32" x 5-3/16" x 9-3/16"
No. of Channels	14
Magazine Capacity	95' DuPont Lino Writ #4
Recording Speed Range	0.5" to 80" per sec.
Trace Identification	Beam Interrupter Type
Constant Acceleration	Above 25 Gravities
Shock Accelerations	Above 1500 Gravities for 20 Milliseconds
Temperature	—65°F to +165°F
Altitude	Up to 100,000' above sea level
Power Requirements	28 volts DC, 12 Amperes Maximum
Connectors:	
Power	WK-5-32S
Galvanometer	FK-C32-32S

This new recording oscillograph now makes it possible to eliminate costly telemetering equipment in missile, torpedo or similar testing. Its miniature size, extreme ruggedness and high recording speeds allow it to be installed directly in the test vehicle, where it will record all data and will withstand the high shocks and accelerations associated with the test.

Rigidity! At equal weight, magnesium is 18 times stiffer than steel

Magnesium's unique combination of strength and light weight gives it some outstanding abilities as a structural metal. Take rigidity, for example. A magnesium bar has 22% the stiffness of a steel bar of the same dimensions.

But stiffness increases as the cube of section thickness. So, if thickness of the magnesium is increased to twice that of the steel, the magnesium bar will be over 70% more rigid—yet weigh only half as much. And if thickness is further increased until the bars are of equal weight, the magnesium bar will be 1878%—or over 18 times—more rigid!

Similarly, a magnesium bar of equal rigidity to an aluminum bar will weigh only 75% as much as the aluminum bar. At equal weight, the magnesium bar will be over twice as stiff.

From these facts it's easy to see that magnesium can do a structural job equal to or better than steel and aluminum—and with appreciable savings in weight—whenever it's practical to increase section thickness. Aerophysics

By Seabrook Hull

Being within a lifetime of extensive space travel, as we are now, certain basic concepts deserve more thoughtful consideration. Not the least of these are some of the fundamental hypotheses of relativity, at which point this column ventures into a phase of astrophysics.

An interesting and disturbing element of Einsteinian thinking is the "apparent fact" that the speed of light is constant to any observer, regardless of the relative motions of different observers observing the same light source. This, of course, is an awkward assumption. Yet wherever capable of being tested and checked, either astronomically or within the confines of some of man's more exotic research equipment, relativistic mathematics is meticulously born out.

If light velocity is constant for any observer, and we measure astronomical distances in terms of light-hours and light-years, then these distances (absolute spacial displacement) must vary for different observers. This concept does not appear to be at variance with relativity. Physical time also is dependent upon the relative motion of observer and observed. And, distance appears to be a function of velocity and time in any coordinate system.

Thus man, in his proximate ventures into outer-space, would seem to be limited in velocity only in terms of earth-bound observation. Relative to the coordinate system of the space vehicle itself, the velocity of light will remain constant, notwithstanding the velocity of that vehicle. This is one of the disturbing but essential assumptions of the General Theory of Relativity. Thus, the velocity of a free vehicle in space seems to be theoretically without limit. Again, relative to an observer on earth, this vehicle's observed velocity would be limited to a fraction of the earth-measured velocity of light.

However, in terms of the "absolute" coordinate system of the space-traveling vehicle itself, there would be no such restriction . . . for the only relativistic limitation on the vehicle's velocity is that it cannot exceed that of observed light. Yet this is constant for any observer, and regardless of the relative motion of that observer, the velocity of light is the same—186,000 miles-per-second. Thus a vehicle covering light-year distances (as observed on earth) in hours would still be traveling at less than the speed of light (as measured by the vehicle).

Pursuing this line of reasoning a few steps further becomes very disconcerting. For example, distance must thus be a function (or friction) of the observer and inconstant by any comparison: Spacial displacement becomes a chance (or optional) variant.

These lines of reasoning, dwelling on so-called Eigen conditions, may well be open to considerable argument, but this column hopes they serve at least to emphasize the real, practical need for: (a) Relating basic thinking theory to upcoming operational problems and (b) reexamining and justifying Relativity in terms of the many more recent (and startling) subnuclear observations. It would also seem to necessitate a new and more careful look at the concept of "free space" itself—the raising of the possibility anew that there is in fact a universal medium (once called the ether), a current source of confusion which, once comprehended, would become absolvent of some of the more fundamental anomalies. In any case, it should be obvious that Einstein's was an approach, not an end to understanding, that already more *thinking* is needed.

O.K. Mr. Satin?

Astrionics

By Henry P. Steier

When will the first *Vanguard*-with-satellite be fired? Seems like a good clue to the answer could be the status of the camera tracking station installations. Latest report from IGY scientists is that cameras will be installed at the rate of one per month starting this summer.

Since a dozen camera stations are planned, it looks as if the schedule for first attempt to place a satellite will be around July 1958. IGY starts July 1957 and runs to December 1958.

Big unknown about the earth and its continents is the distance between various points on earth's surface. Some guesses are that we are miles off in distance information between continental European and North American points.

Any planning for ICBM use would need most accurate distance information possible. Planned IGY camera tracking should add whole new orders of distance information accuracy to our fund of information. Data from cameras is expected to bring accuracy to within a few feet. Such information will be an important factor in data fed to big computers for calculating ICBM trajectories.

•

Recently a physicist came up with another idea on distance measurements. He said atomic powered submarines might be used to measure point-to-point distances between coastal areas. He suggested that the constant speed capability of these subs while submerged would make them useful for deriving distance from point-to-point times obtained.

First need for accurate distance information will probably be during ICBM test flights off the coast of Florida. These will be in the same general direction as the satellite launching. Recently reported was a plan to set up Air Force electronic missile tracking gear on the island of St. Helena off the African coast. Distance to that point, for example, would be most useful in evaluating ICBM tests.

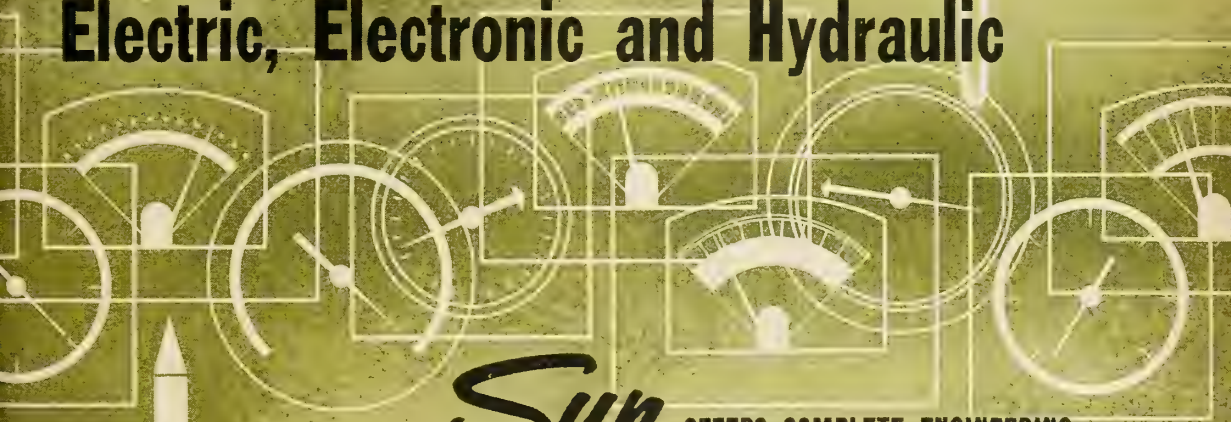
•

Phase angle tracking systems similar to the Minitrack stations to be used for tracking the satellites' positions is "old hat" to the Cubic Corp. Similar systems built by Cubic have been in use at Patrick AFB for some time. Called DME-COTAR, phase angle measurements are used in this system for determining test missile trajectories, distance and position data. Operating at between 200—450 megacycles, tracking accuracy is said to be much better than with radar. Accuracies of two feet in distance at 200 miles and 0.03 mils in direction are claimed. Cubic expected it would get the Minitrack contract for the satellite program but lost out when the Navy developed its own system.

•

In the midst of speculation about whether the press will be permitted to view the first *Vanguard* launching is hope for on the spot viewing by the general public if the military will permit it. Rumor is that International Business Machines Corp. is negotiating to sponsor a big TV broadcast of the event.

•



Note to lady rocketeers: A Latin American gentleman has a suggestion on how to shorten the time to moon travel. Dr. John P. Hagen, Project *Vanguard* Director was asked at a recent press conference, "When will the first moon trip be made?" The inquiry came from Maximilian Garavito, Editor and Publisher, "Revista Aerea Latinamerico." Hagen said he preferred to answer in terms of money and engineering needed rather than time. Senor Garavito then said he saw no reason why, since Columbus discovered America using money from jewels pawned by Queen Isabella, the women of America could not give their "jewels and stocks" for the first moon ship.

To Power control and test equipment: Electric, Electronic and Hydraulic

Sun OFFERS COMPLETE ENGINEERING, DESIGN AND CONSTRUCTION FACILITIES OF THE HIGHEST STANDARD OF RELIABILITY

SUN Equipment is known for its Reliability. Whether it be a simple d'Arson galvanometer meter, an oscilloscope specially circuited for specific instantaneous readings, or a large and complex hydraulic power supply and remote control testing unit for missiles or rockets—the reliability of SUN Equipment can be depended on with the utmost of assurance.

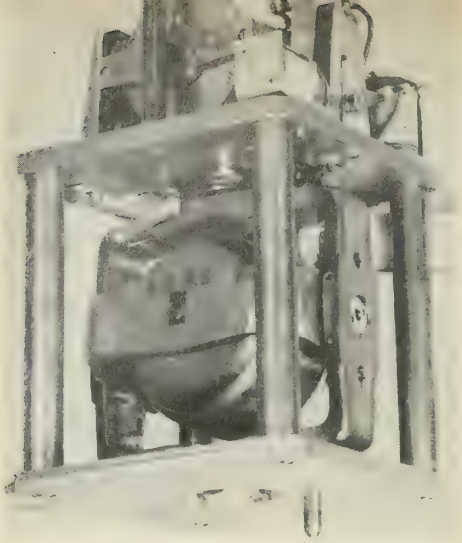
SUN Equipment has proved itself reliable for 30 years in industries whose requirements are as exacting as those of the aeronautical and astronautical fields.

Whether your problems and needs are concerned with:

Ground support test equipment for missile systems.

Quality control test equipment for missile component functions.

Firing stand test equipment or



In-factory functional test equipment.

our engineering and manufacturing facilities are available to you. And we are sure you will find them the finest extant in our fields. We welcome your inquiry.

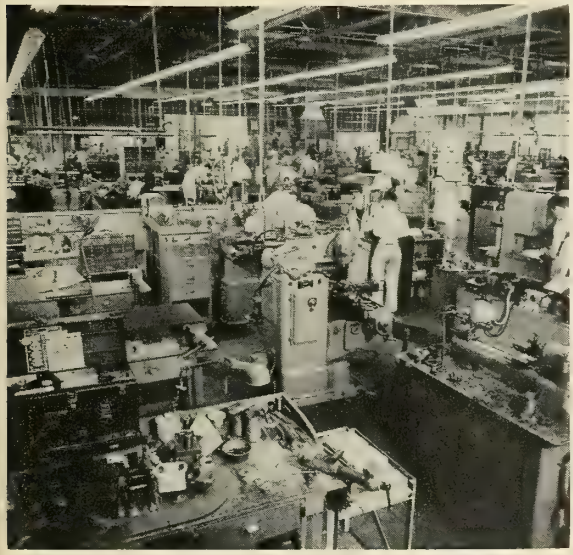
Birth of a Torpedo Gyro System

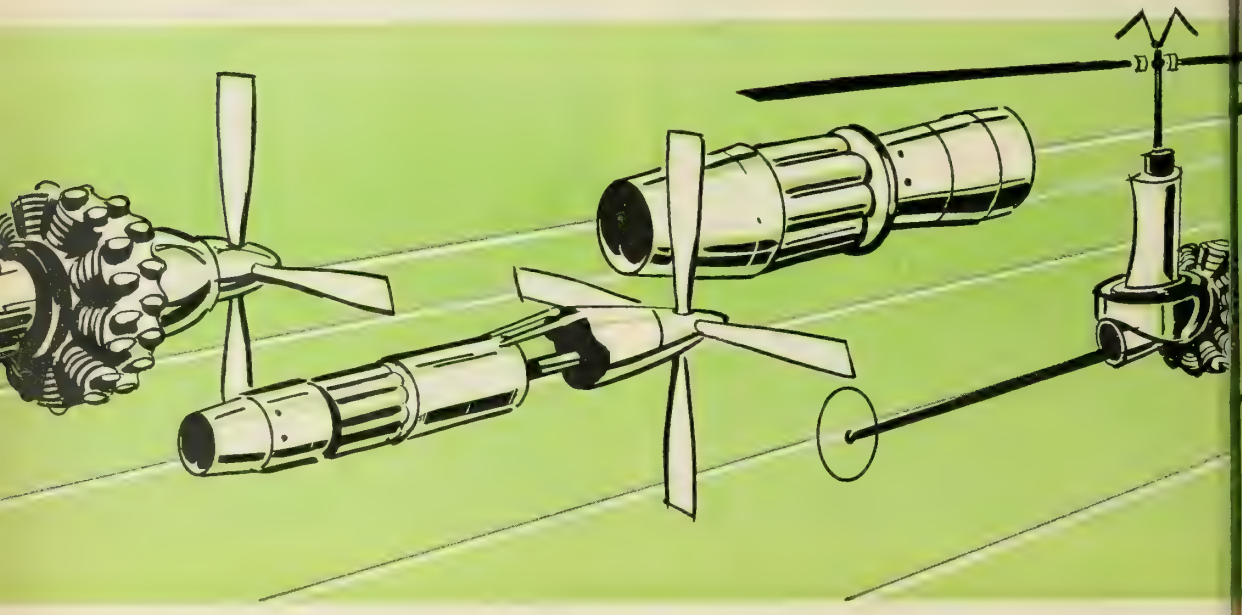


The torpedo gyro essentially serves a course control function and provides a safety measure against anti-circling to return. On the drawing table at Whittaker Gyro an experimental model is designed. From these specifications the prototype department builds component parts and tests them. When all components seem acceptable, a complete instrument is assembled and subjected to a thorough checkout. The new torpedo gyro now goes to the drafting table. The designers convert computations into a working design from which a prototype model will be built.

Following assembly the gyro is then sent to the test department. Specialized test equipment is needed to meet requirements and quality control measures. These include full function and environmental testing. Here, a test engineer subjects the course control gyro to high frequency vibration and acceleration tests.

To supplement the standard parts which are ordered from outside sources, the machine shop, shown here; turns out the precision components which are peculiar to this type of torpedo gyro.

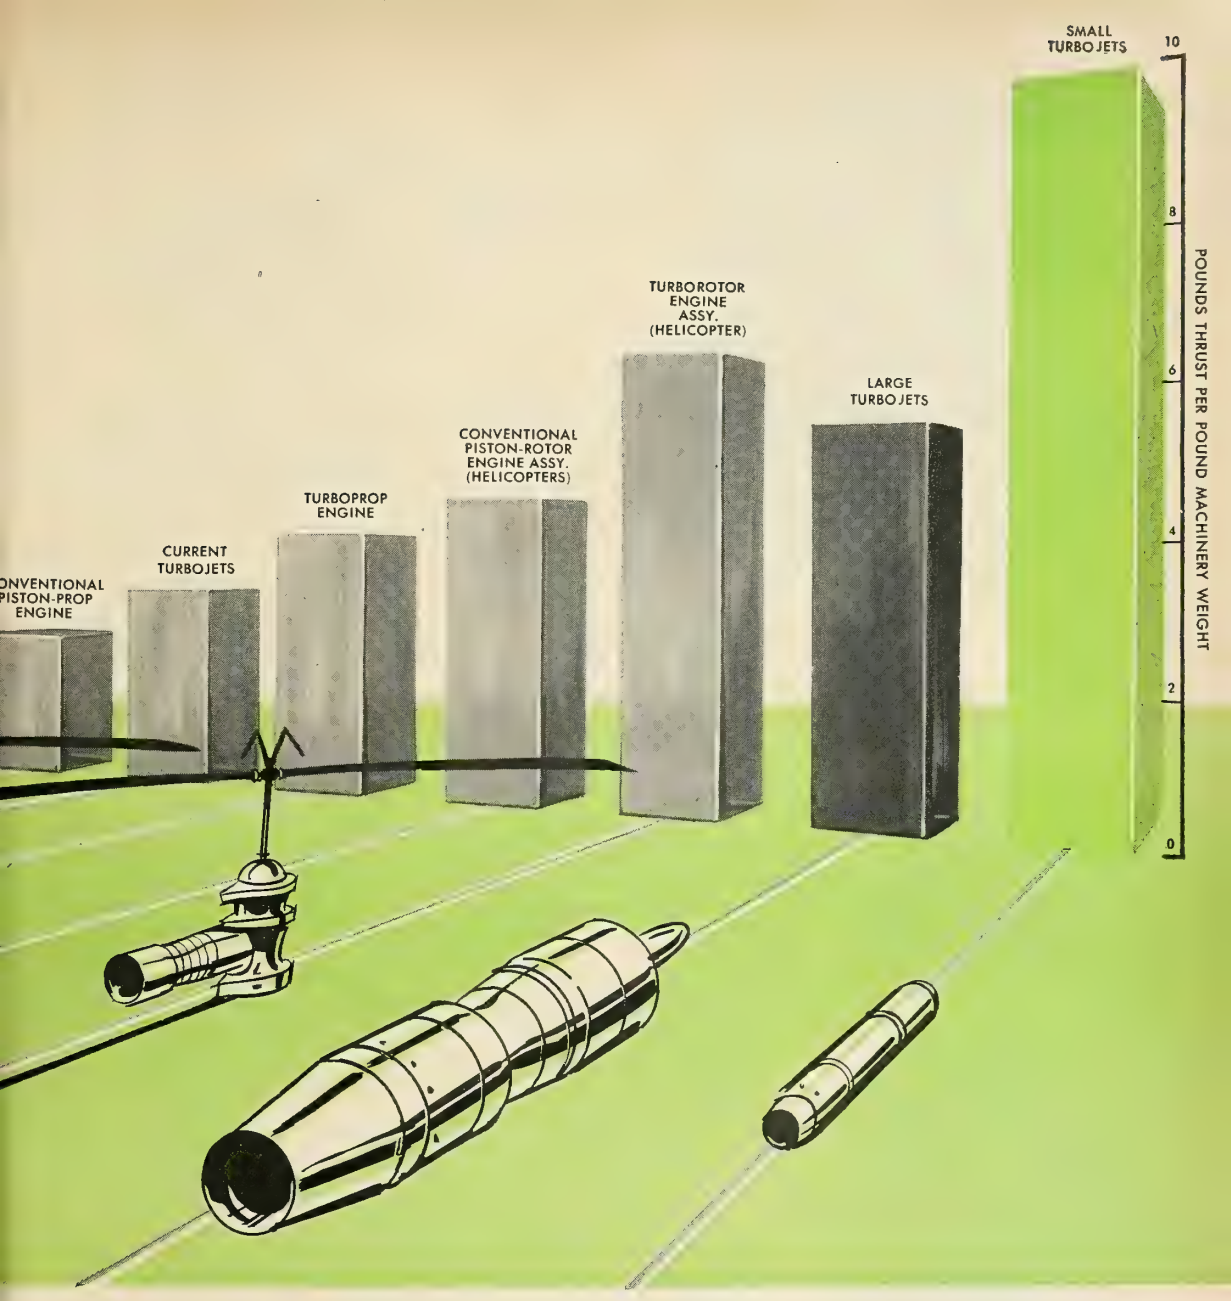
The course control torpedo gyro is assembled in rigidly controlled atmosphere where temperature and humidity are constantly regulated. Any one entering the room must put on a nylon smock.



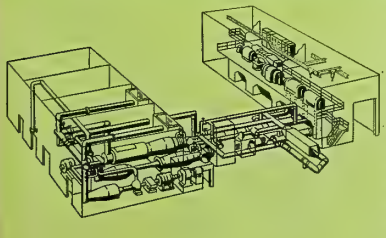
The gyro is packed and inspected, boxed and re-inspected before it goes into delivery channels. The magnitude of importance which this gyro will play in the guidance system of the modern day torpedo will justify the intricate preparation and care which follows each of these instruments to its destination.

SMALL JET ENGINES . . . CHAMPION WEIGHT LIFTERS

An entirely new family of aircraft will evolve from a new family of small lightweight jet engines now under development at the Fairchild Engine Division. These new powerplants will feature incredibly high thrusts and great lifting power...yet will be so light they can easily be carried by two men.



Highly compact, with low frontal areas, the small jet engines will deliver thrust/weight ratios starting at 8 to 1 with a long range potential of more than 10 to 1. They will be used in the high performance, lightweight trainers, interceptors, target drones, pilotless aircraft including missiles and intermediate class passenger and cargo jets of the nineteen sixties. They will also be used to power fighters and utility cargo craft, executive aircraft . . . and will make jet Short Take Off and Landing (STOL) and Vertical Take Off and Landing (VTOL) aircraft practical.



The small jet engine may be used singly, in pairs and in clusters. It provides multi-engine reliability in aircraft of a size now wholly dependent on a single engine. The small jet engine will produce greater versatility and utility in airplanes of tomorrow.

COMPARISON OF LIFTING CAPACITY OF POWER SYSTEMS

How the new family of Fairchild Small Jet Engines compare with other mechanical lifting systems.

The extensive research facilities at Fairchild Engine Division have been designed solely to test performance of the small jet engine. They range from full scale, high altitude test chambers to supersonic research for component design. Fairchild Engine Division has spent a decade in the design, development and production of small, powerful jet engines.

GYROS...
To Prevent Torpedo Vertigo

By Donald J. Rammage
Whittaker-Gyro

ONE OF THE MOST important advances in our country's weapon arsenal has been the development of the sonic homing torpedo. Although, the gyroscopic principle was involved in earlier torpedo experiments, it became increasingly important in sonic homing torpedo development where its role in the guidance system effected great changes.

Before the advent of the sonic homing torpedo which had its beginnings in World War I, the gyroscope was used to keep the torpedo on a straight course to the target. But it was costly to produce.

In spite of all efforts to increase the accuracy of the gyroscope and consequently the torpedo itself, the percentage of target hits was low. This was not due entirely to unreliability. The vessel under attack might spot the torpedo and take evasive action or it might be steering a zig zag course and change course after the torpedo had been fired. This demonstrated the need for a device to automatically cause the torpedo to home on the target.

Modern gyro for the sonic-homing torpedo. Small yet extremely reliable, Model 501705 is light and low in cost.

With the development of such a device, the gyroscope's role in the torpedo was immediately changed. It was no longer necessary to build extreme accuracy into the course control gyroscope. Most inaccuracies could now be overcome and corrected by the electronic sonic homing device.

While this would appear to give the gyroscope a back seat in torpedo guidance, it was found that it was still required. It was necessary to have a stable directional reference that would work in conjunction with the sonic homing device.

Before World War II the design, development and production of standard torpedoes was done largely by the Navy in its Ordnance plants. The all important directional gyro was also manufactured in the Ordnance plants. At the beginning of World War II, these plants were under terrific pressure to produce torpedoes in quantity under trying conditions.

Such programs were of high priority and there appeared little, if any, incentive for the development of the sonic homing torpedo. Up to this time, almost sole concern had been for torpedo accuracy as aimed and launched from a surface vessel or submarine. Our staggering losses during the war pointed up the need for a torpedo which could seek out submarines.

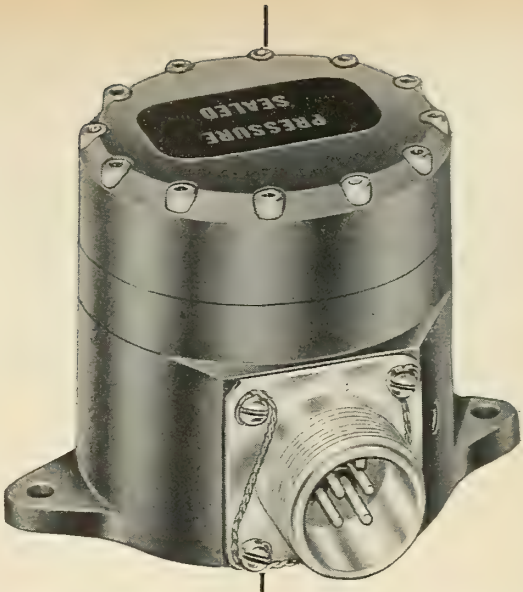
The experts at this point reached the conclusion that the homing torpedo had a multi-delivery capability—the same type torpedo could be launched from a ship, aircraft, blimp or a submerged submarine, seek out and kill with equal results.

It was decided early in the development that an electric drive would be required as well as non-cavitating propellers so that no tell-tale trail of bubbles would reveal position. To obtain counter propellant rotation (to keep the torpedo on a straight course) it was necessary that one set be driven with the shaft of the starter motor and the other set with the frame. This necessitated mounting the drive motor (automobile starter) with a set of bearings on the housing and bringing power to it through slip rugs. The need for electric power to drive the torpedo and operate its electronic equipment dictated the gyro's operation from an electric power source. Previously the gyros had to be air driven as this was the only power available in the torpedo.

At the stage of the hot-water-tank-and-breadboard-equipment no depth control mechanism was available although the feasibility of the sonic homing torpedo had been established. The development of this one remaining piece of equipment stood in the way of the entire program. Depth controllers were used on the standard torpedo but they were allowed high priority.

At this point fate intervened. One of the principal design engineers had undertaken some do-it-yourself hot water heating system repairs in his home. He was directly concerned with the controlled-submersion problem and this caused him to consider the principles of the pressure regulating mechanism. Here he found the device that was needed: essentially bellows and two electric mercury switches. He dismantled it from the heating system and a quick test in the following days proved its capability for the job.

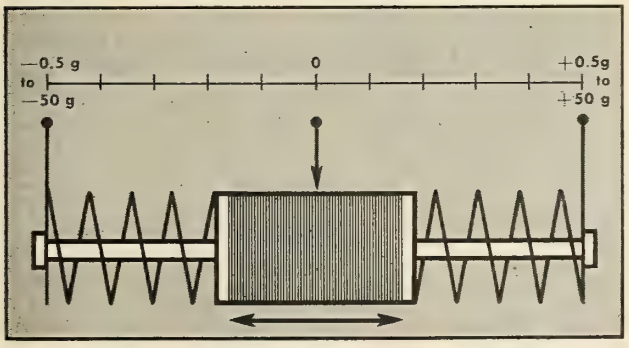
While the development of the sonic homing torpedo proceeded, John James came to the Underwater Sound Laboratory at San Diego to assist in the development of a decoy-type torpedo. This device was to be launched from a ship being attacked by sonic homing torpedoes and by virtue of the quantity launched, undertake to decoy the sonic torpedo away from the ship.



During the latter part of World War II, several other firms were working on development and improvement of the sonic homing torpedo. Among these were the Bell Telephone Laboratories with Western Electric Company as the production group.

Each group was working on a different torpedo for particular tac-

LINEAR ACCELEROMETERS



for Aircraft and Missiles

ZERO CROSS-COUPLING NON-PENDULOUS TYPE

Shown Actual Size

Honeywell Linear Accelerometers sense positive or negative accelerations or both in either the vertical or horizontal plane. Designed for use in aircraft and missiles, they are available in a variation of ranges from ± 0.5 g to more than ± 50 g's depending upon requirements. These units consist of a centrally located mass restrained by coil springs and supported on a linear-type ball-bearing. Any movement of the mass on either side of the null displacement position is measured by a potentiometer pick-off, providing a high level output signal. Viscous damping is incorporated for improved dynamic response. Zero cross-coupling is inherent with this true linear non-pendulous design. (Cross-coupling is defined as a change in output signal caused by an acceleration applied from any direction in a plane normal to the sensing axis) Excitation may be as high as 100 volts (A-C or D-C) depending on the potentiometer resistance. *Write for Bulletin LA . . .* Minneapolis-Honeywell, Boston Division, Dept. 45, 1400 Soldiers Field Road, Boston 35, Mass.

Mark 27 torpedo gyro. Accurate, predetermined course can be established by presetting the course-sensing element.

tical missions but all were using the sonic homing principle.

Whittaker Gyro with its work in the direct-current-powered gyro field was able to use basically similar gyro wheel and gimbal configurations and supply different sensing elements, caging mechanisms, case configurations.

The gyroscopes for the Mine Mark 30, the Mark 27 and the Mark 32 torpedoes contained gyroscopic elements modified from the roll control free and rate gyro and Air Force Type B-10 used in the *Azon* and *Razon* radio-controlled air-to-ground bombs.

The first sonic homing torpedos operated so that they homed on the noise generated by a ship's propellers and were primarily designed for use by submarines against surface ships.

The gyroscope for the Mark 27 was designed so that it could be given an initially determined course by presetting the sensing element before launching. The gyroscope was therefore designed so that the gyro's course-sensing element could be remotely set by means of a selsyn system operated from the fire control center.

The complete gyroscope package was mounted to the internal surface of the hull. By removal of a plate in the hull the gyro could be caged and an initial course set by hand into the gyro sensing element.

Once this was done the torpedo would then proceed along this predetermined course for a certain distance where the gyroscope would be electrically disconnected from the system and the sonic homing device would take over. It would become the controlling element for course control to the target or surface vessels.

At this point, it became apparent that the sonic homing torpedo required sound on which to home. It was obvious that the defense against such a weapon would be to stop the ship and shut down all power, cutting off all noise.

Another approach was to have the torpedo send out a sound wave and pick up the sound reflection from an object in the water. Thus a sound from the target would not be required. This approach was used in the Mark 32 which was produced by Philco.

This type of torpedo has a wider variety of applications than the basic sonic homing torpedo. It can be launched from ships, airplanes, surface vessels, blimps and helicopters. It does not need to be initially aimed. Once in the water it can look for a target.

For one such torpedo model a rate gyro was used for the course control. The rate of turning for the torpedo either to port or starboard had to be established. To accomplish this Whittaker designed a rate gyro with a sensing element consisting of switch contacts which would establish a turning rate.

The rate gyro portion of this instrument was given a new frame and sensing elements. With this type of gyro control, a search program can be established and the torpedo can continuously circle or proceed in any desired direction by means of a series of turns, first to port and then to starboard.

Another type of gyro, used to establish a search program, is a free gyro whose course-sensing device can be rotated by an electric motor which can be programmed. The programming can then cause the torpedo to circle in the direction desired or to proceed on a straight course until the torpedo hears the target. The sonic homing device overrides the gyro and directs the torpedo to the target. This gyro is used in the Mark 43 torpedo.

After World War II most development work on weapons was slowed down, the Korean War spirited production of the sonic homing torpedo. Whittaker Gyro found itself in the position of being unable to supply all the demands for gyroscopic instruments.

It was necessary as a compromise to furnish major gyro components to the government and prime contractors. They in turn completed the gyroscopes for use in the sonic torpedos.

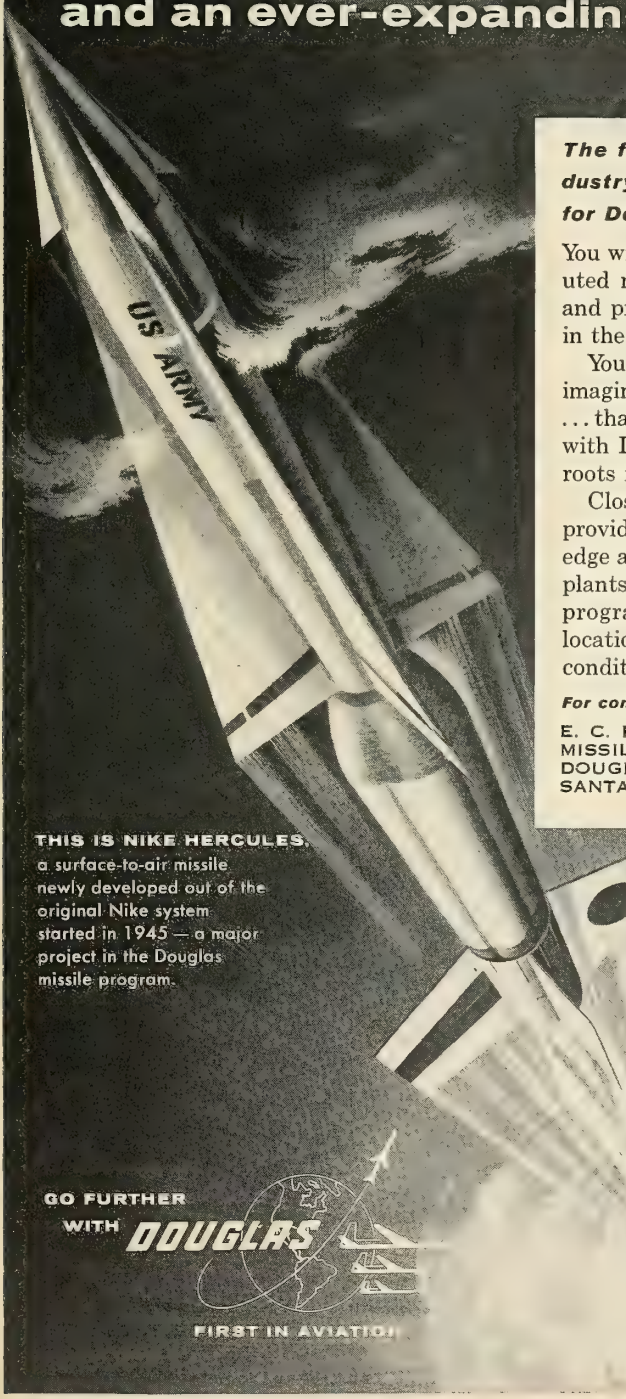
In the years between World War II and the Korean conflict, major developments had been made in the manufacture of gyroscopic instruments and as soon as it was possible, Whittaker Gyro undertook the development of a gyroscope especially designed for use in sonic homing torpedos. Up to this time the gyros this company turned out for the various torpedo programs had been modified types originally developed 10 years earlier.

It was thought by many of the torpedo manufacturers that because of the decreased accuracy requirements of the gyro for sonic homing torpedoes they could be made at extremely low costs. However, this was not the case.

It was found that many of the torpedoes were used in applications where the torpedo and gyroscope were subjected to high shocks, high sustained accelerations, high vibration, wide trying tension temperature variations and other extreme environmental conditions. Further, small size and light weight were more in demand.

The design of the gyroscope for the modern sonic homing torpedo must take into consideration many factors in addition to basic sensing accuracy. These include the tactical mission of the torpedo, the environment conditions to which the gyro will be subjected both during its final mission and en route to its final mission. It must have exceptional reliability and lastly be of small size, light weight and low cost.

To design a gyro, taking these factors into consideration and weighing each one in relation to cost, has required extensive research including the evaluation of many design approaches and countless tests.



The culmination of the research and development has resulted in the production of the Whittaker Model No. 501705 gyro. This instrument incorporates many innovations such as monel gimbals which derive their strength from the use of spherical and cylindrical shapes. This has allowed the use of thin sections which reduce the weight of the components to little more than if made from aluminum.

The use of monel has eliminated the need for corrosion protection on the major parts. The use of monel has also eliminated one of the major problems created by wide changes in operating temperatures.

The coefficient of expansion of motor shafts, gimbals, and frames are now made of materials which essentially have the same coefficient of expansion thus maintaining dimensional tolerances between major components. This prevents creation of damaging forces on the bearings or the creation of too great clearance between parts which could cause unbalance. Major components have been designed for fabrication by punch press and screw machining.★

WHY DOUGLAS ENGINEERS AND SCIENTISTS GO FURTHER . . .

At DOUGLAS, your career in missiles is backed by sixteen years of experience and an ever-expanding future

THIS IS NIKE HERCULES, a surface-to-air missile newly developed out of the original Nike system started in 1945 — a major project in the Douglas missile program.

The finest talents and facilities in the industry have earned an outstanding position for Douglas in the national missile program.

You will become part of a team that has contributed more to the research, design, development and production of missiles than any other group in the nation.

You will work on projects that challenge the imagination . . . that stretch out far into the future . . . that let you plan a secure and rewarding career with Douglas. Many of these projects have their roots in the mid-forties and are still growing.

Close coordination of missile and aircraft work provides an interchange of experience and knowledge among Douglas engineers and scientists. All plants are engaged in some phase of this missile program . . . making possible a broad choice of locations where you can work and establish living conditions suited to your taste.

Cavitation—an equivalent of aerodynamic turbulent flow—troubles both ends of a torpedo. Fig. 1 shows propeller turbulence; Fig. 2, cavitation at the nose cone.

HYDRODYNAMICS
The Art of Silence

by Prof. George F. Wislicenus
State University of Pennsylvania

THE TORPEDO is a submerged body kept suspended in its medium primarily by its buoyancy, and is therefore hydrodynamically a first cousin to the rigid air ship or "dirigible" rather than to airplanes.

Considering the well advertised advances in the torpedo's most important target, the submarine, it can be taken for granted that demands for increased speeds will be ever-present. Considering that the density of water is about 900 times that of air at moderate altitudes, this isn't going to be easy.

From the point of view of drag the classical torpedo speed of 45 knots may be regarded as equivalent to airplane speeds in the neighborhood of 950 knots.

Since the velocity of sound in water is of the order of 4000 feet per sec. It is immediately evident that the "Mach numbers" of the bodies travelling at foreseeable speeds under water are very low compared with all airplane speeds now in use.

There exists however, in hydrodynamics a phenomenon quite analogous to the compressibility or Mach-number effects in gases which becomes effective, and is indeed of decisive importance, within the speed ranges of torpedoes as well as submarines.

The hydrodynamic phenomenon that plays the same speed-limiting role in connection with liquids as "Mach-number effects" in the field of gas dynamics, is known as cavitation. Cavitation is defined as the local vaporization of a liquid in motion, caused by local pressure reductions resulting from the dynamic actions of the liquid.

These local cavitation voids have a detrimental effect on the overall efficiency of the device. Cavitation also causes mechanical damage, but most importantly, it is noisy. The very onset or "inception" of cavitation, barely visible to the eye under favorable test conditions, has been found to be acoustically as harmful as more extensive cavitation. This interferes with sonar-directed torpedoes.

The parts of torpedoes most susceptible to cavitation are the propeller blades since, by virtue of their helical (screw-like) motion, these blades cut through the water at a higher speed than the torpedo itself. Aeronautical airfoil data apply directly to these most critical parts of a torpedo.

The local pressure reduction is usually expressed as a certain fraction of the "stagnation pressure" $PV^2/_2$. This fraction (Cp) is called the "minimum pressure coefficient." It can be derived directly from airfoil data pertaining to "critical" flow conditions with respect to locally sonic flow. The range of favorable i.e. low values of Cp is smaller the thinner the airfoil.

On the other hand thin airfoils are necessary if low values of Cp are required. This simply means that the more refined the design to meet increased demands of good cavitation performance, the greater will be its sensitivity to departures from design operating conditions.

The practical significance of the pressure coefficients, given for example in Fig. 3, is illustrated in Fig. 4 by applying these data to the blades of a torpedo propeller. It was assumed that the peripheral velocity of the propeller is twice as great as the forward velocity of the torpedo so that the velocity of flow relative to the blades is $\sqrt{5}$ times the forward velocity (v) of the torpedo and its propeller. (This assumption corresponds to an "advanced ratio" $J=V/n \circ$ of 1.57) Fig. 4 gives the velocity of advance as a function of the depth of submergence for two different blade pressure coefficients (cp) as may be derived from Fig. 3. It is seen, for example, that a speed of 40 knots would demand for cavitation-free operation a submergence of over 50 ft. provided the thinnest blade section listed in Fig. 3 (6% thick) is used having a pressure coefficient of about 0.25. It should be noted that such a thin blade section will have such a low pressure coefficient only if the flow meets the blade within slightly less than ± ½ degree of the design angle of attack. This illustrates the precision with which design conditions must be met to avoid cavitation under actual operation.

It is also evident from Fig. 4 that with a higher blade pressure coefficient,

say 0.50, as may be expected with blades of about 12% thickness, cavitation-free performance can be expected only at moderate speeds or very great depths of submergence. This explains why hydrodynamic propellers have usually rather thin blade profiles.

The sensitivity of a high-quality propeller, explained in the preceding section, makes it clear that cavitation-free operation may be difficult if not impossible to achieve on the basis of theoretical design procedures only.

Prior to field testing it is desirable to determine the hydrodynamic performance characteristics of a new torpedo under the controlled conditions of the laboratory. The "Towing Tank" has been successfully applied to the development of torpedoes.

For more detailed observation, particularly regarding the location of incipient cavitation, the Navy's Bureau of Ordnance has built a large Water Tunnel at the Pennsylvania State University.

The most important test variable with respect to cavitation is, of course, the pressure which can be changed over a wide range without affecting other test conditions.

It should be recognized that the simple description of the cavitation phenomenon given above is far from complete. It is not at all evident why cavitation should take place exactly at the vapor pressure of the liquid as measured under certain standardized and steady laboratory conditions.

Considering, for example, that cavitation might be expected to start with microsopically small bubbles, it is somewhat surprising to find that the surface tension of these bubbles apparently does not play a clearly definable role in cavitation inception.

Another problem is the possibility of scale effects in testing, whereas, pressure coefficient is a ratio of two pressures and as such is independent of absolute dimensions or of velocities, the question must be answered whether there are perhaps significant "scale effects" present when applying the test results obtained at one scale and velocity to another scale and velocity.

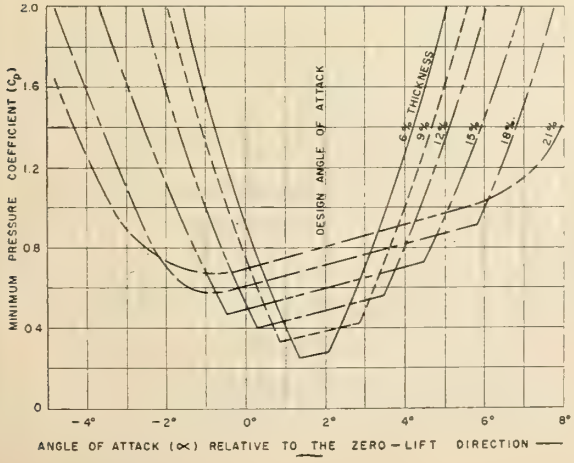
There are several other problems in the field of cavitation that are urgently in need of rational answers. For example, the effects of accidental departures of blade or body contours from their ideal design forms, such as surface roughnesses, certainly deserve careful attention, as such departures are in practice not to be avoided.

Another problem that still awaits a practical solution is that of the interaction between stationary control surfaces and rotating propeller blades.

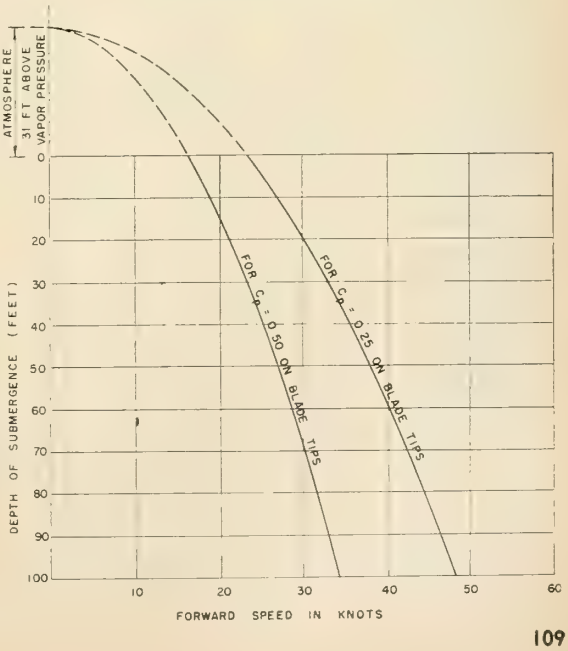
Cavitation is by no means the only hydrodynamic problem. Hydrodynamic stability and control of the submerged body is of decisive importance, the more so since target seeking torpedoes must meet higher demands with respect to maneuverability than the old, straight-running weapons.

The towing tank as well as the water tunnel are available to test torpedo bodies under various inclinations against the direction of the flow and with various deflections of its control surfaces. Means for measuring the forces acting on the body under these operating conditions are available or under development.

It may be surprising that the problem of hydrodynamic efficiency has hardly been mentioned in this article. Today well designed torpedoes are hydrodynamically so efficient that no advancements in this respect are to be expected without correspondingly major developments in the control of the flow processes that are responsible for the hydrodynamic behavior and resistance of submerged bodies.



The question has frequently been raised whether certain kinds of nature's best swimmers, such as the porpoise or the barracuda, suffer none of the torpedo's limitations.

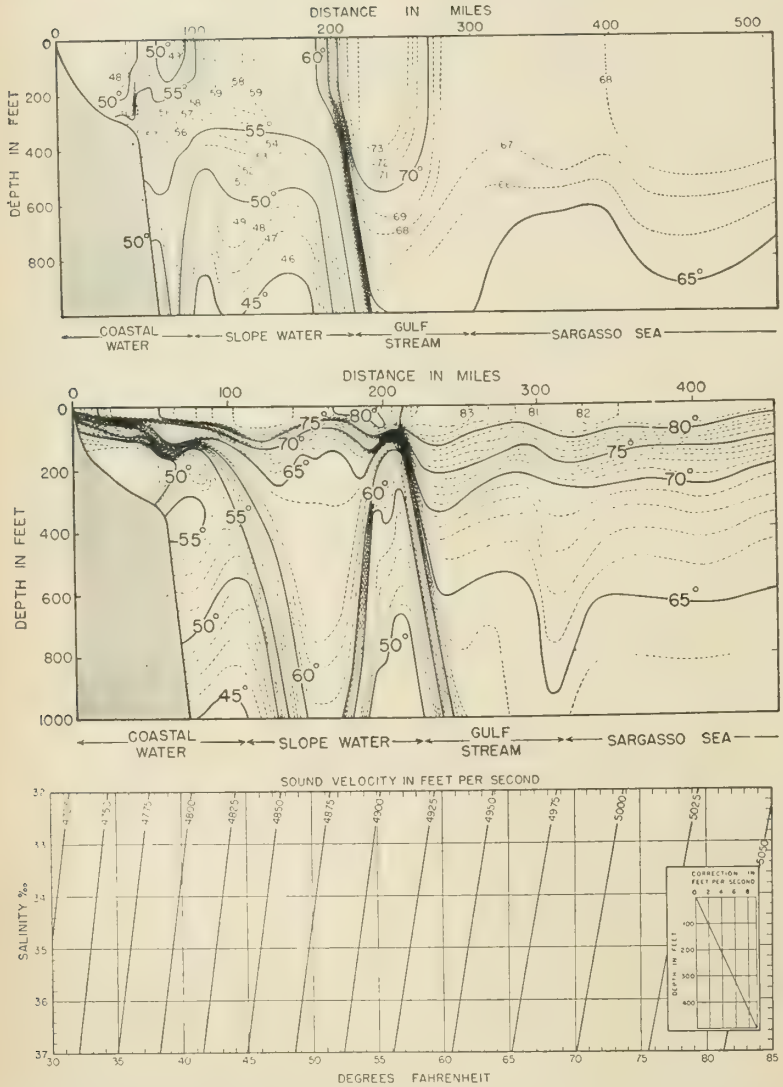


The only clearly foreseeable reason why such fish may have an appreciably higher hydrodynamic efficiency than torpedoes is the possibility of maintaining "laminar" flow over the entire body, which is certainly not true for torpedoes. The problem of maintaining laminar flow in the bounder layer of torpedoes has been much studied.

Laminar flow airfoils have been tested and found to perform in accordance with the theoretical predictions provided one is able to maintain an extraordinarily high quality of surface finish. Particles as small as small flies sticking to the surface of the wing were found to bring on turbulent flow.

Therefore the practicability of achieving such advances under actual operating conditions is as yet highly questionable. It is thus evident that far-reaching advances in the hydrodynamic efficiency of torpedoes will demand more than modern fluid mechanics can readily offer at the present time. In this respect the torpedo engineer is fighting on the very forefront of this broad field of applied science.★

Immediately below (in Fig. 3) is a plotting of the minimum pressure coefficients for a typical series of modern NACA airfoils (NACA Rpt. 824). These data are almost directly applicable to hydrodynamic phenomena. To the right (in Fig. 4) it is applied to torpedo propeller blades for which the peripheral velocity of the propeller is twice as great as the forward velocity of the torpedo so that the flow relative to the blades is $\sqrt{5}$ times the forward velocity of the torpedo.



A Realm that Needs Only More Understanding

the OCEAN

By Seabrook Hull

Top diagram shows a temperature profile southeast from Montauk Point in midwinter. Below is a salinity profile taken simultaneously. Bottom chart shows how sound velocity varies with temperature and salinity, including depth correction. Changes take place daily and seasonally.

PURE WATER is a wonderful thing. In the metric system, at least, many of its constants are unity—one calorie of heat raises one gram (or one cubic centimeter) of water one degree centigrade. As a medium it's constant and reliable, and all of its properties are well known. To the laboratory chemist, it's tool, reference and standard medium.

But take 1,370,323,000 cubic meters of the stuff and dump it on an oblate sphere some 8000 miles in diameter so that it fills the valleys, ravines and low-lying plains until it covers nearly three quarters of the surface of that sphere to a mean depth of 3795 meters. Set the sphere spinning on a cocked axis at a rate of 15° of arc per hour, and orbit it in an ellipse around an immense white-hot sphere. Now load this nice simple chemical, water, with a heavy concentration of a miscellaneous mixture of salts. Envelop it in a thick layer of gas. Endow it with the greatest known concentration and variety of biological life. The one-time chemist's friend gains a new name—the ocean—and becomes the missile-man's nightmare.

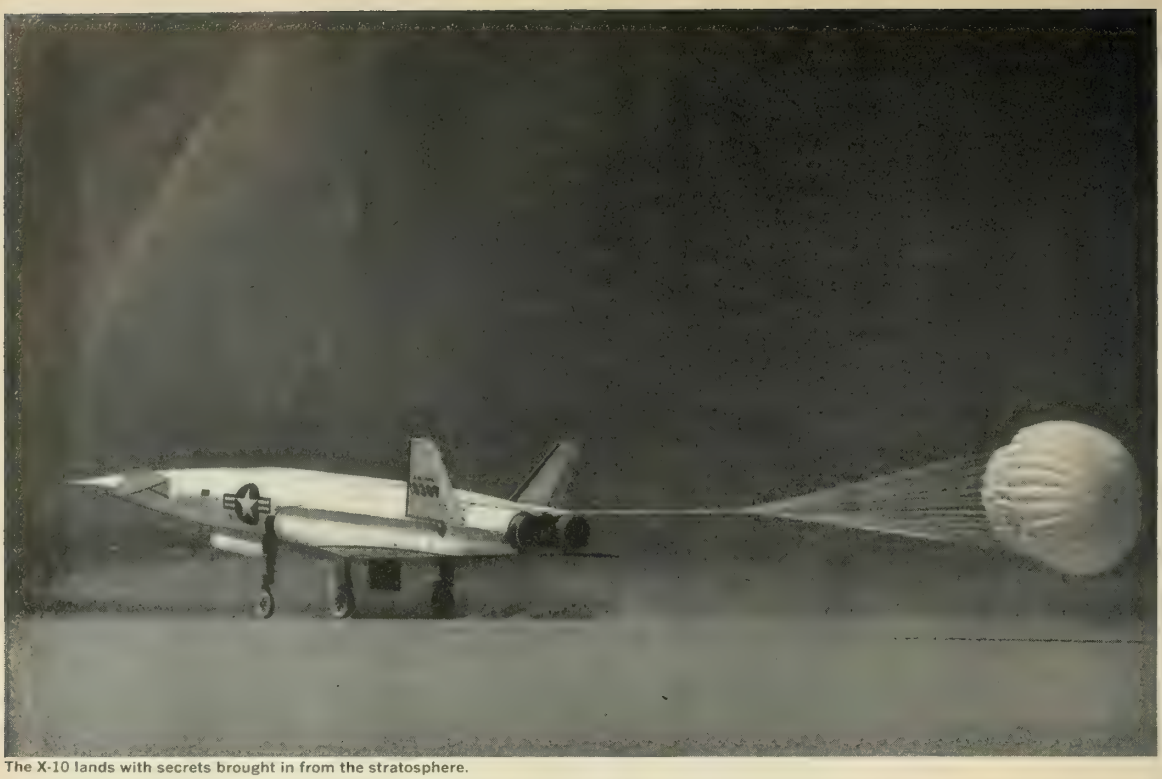
As an environment for manned and unmanned vehicles the ocean has both desirable and hair-raising characteristics. But like space, it's a coming medium for man's endeavors, both military and peaceful. This article aims at providing missilemen of all types with a primer on its nature and properties. To cover it well took H. U. Sverdrup, M. W. Johnson and R. H. Fleming over 1000 pages in their book, "The Oceans." And even they will admit that the sea volumes of the world constitute one of the greatest unknowns known to men.

The major difference between the air and the oceans is biological life. Floating plants and small floating animals in the upper couple of hundred

Fabulous past... Exciting future!

8000 ACRES OF ISOLATION

Fifteen miles from Redlands, California, in 8000 mountainous acres once charted as part of a vast Spanish land grant, Grand Central Rocket Co. has set up a new rocket test facility.



This section of California has a colorful and romantic past. Nearby are graceful missions built by the Spanish padres nearly two hundred years ago. Among the mountains are deserted mines and "ghost towns" recalling the era of the gold rush. The test site itself has yielded the remains of an Indian settlement. This is the land that knew such men as Kit Carson and John C. Frémont.

Great men of the past depended on vision, daring, and leadership to accomplish their goals. Grand Central is using these same principles in the greatest adventure of our time — the conquest of outer space.

Minutes away, fertile valleys with prospering towns and cities beckon to the science adventurer of today. To investigate your *career potential in healthful and friendly inland Southern California, contact the Personnel Manager.*

X-10 missile test vehicle returns with good news for electrical engineers

New scientific data allows the Navaho Missile to leapfrog many R & D steps — go direct into advanced stages. Unprecedented success of the supersonic X-10 spells out this significant fact: The Navaho—an intercontinental strategic missile completely automated and constantly guided throughout its supersonic flight by self-contained control systems—is one of America's *most advanced* missile systems.

This news is important to you—whether you are a 10-year veteran or a recent BSEE. Why? Because now you can start at the very top of missile technology—and reap the rewards of being with a years-ahead company.

40 immediate career opportunities in electronic systems analysis

In Missile Engineering you'll investigate applications of automation that are literally strides ahead of the field. You'll pursue them in pre-flight, preparation, checkout, fueling, countdown and firing. You'll work on "in-flight" control and guidance systems so precise that even the environment within the missile must be rigidly controlled.

One of our immediate needs is for electrical engineers—especially those qualified in systems analysis, systems evaluation, component design and ground checkout. No matter what your experience has been it can be useful to us.

For complete details on these—and other engineering openings—please write: Mr. R. L. Cunningham, Engineering Personnel Manager, Dept 495MAR5 Missile Development Division, 12214 Lakewood Blvd., Downey, California.

MISSILE DEVELOPMENT DIVISION

NORTH AMERICAN AVIATION, INC.

Torpedo fired to simulate aerial launch at Naval Ordnance Test Station, Inyokern, Calif., cavitates and porpoises clear of the water and almost 90° off course. This sort of thing is one of the biggest problems in underwater missile design; is a big reason why more study of the ocean and fish is needed.

meters are so dense sometimes that they record on depth meters with the strength of a solid floor. Bigger swimmers—blue whales get over 100 feet in length; weigh up to 150 tons—live both both near the surface and at great depths. Those animals that spend all of their time in the dense black world several thousand feet below the ocean's surface are all mouth and stomach.

The deepest man has ever been in the ocean is 14,000 feet in a free, self-propelling device similar to a small submarine and known as a bathescape. Probably no submarines have ever been below 1000 feet and survived—their normal maximum operating depth being on the order of 500 feet.

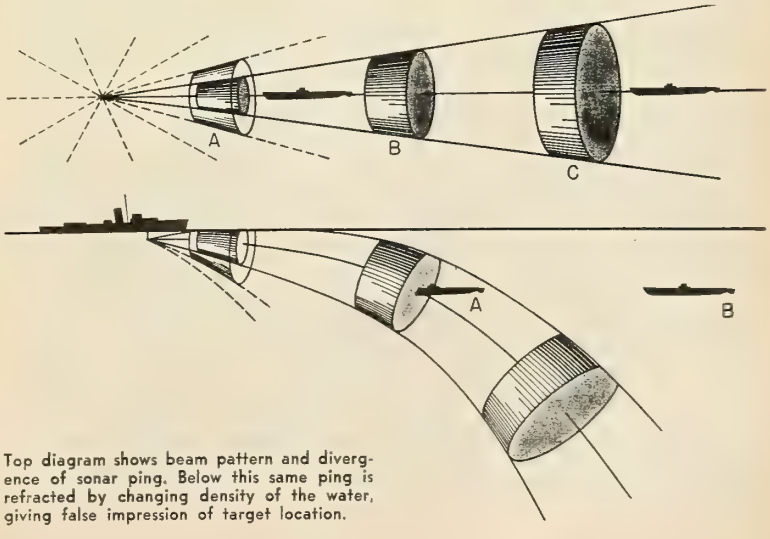
The ocean covers 71 per cent of the earth's surface. It is a three dimensional medium, with mean depths in the Atlantic Ocean of 3926 meters; in the Pacific, 4282 meters; and in the Indian, 3963 meters. The Mindenao trench in the Western Pacific is 10,500 meters with an ambient pressure of 16,000 pounds per square inch. It's the deepest known.

The ocean is similar to the atmosphere in that: it is continually in motion (the jet stream is analogous to the Gulf stream); it has permanent current features; there are oceanic fronts, sharp thermal gradients over short distances; whereas in the atmosphere there are altitude layers known as the troposphere, tropopause and stratosphere, in the ocean (going down) there are the troposphere, thermocline and stratosphere; the two mediums have similar and common boundaries—the earth's surface and each other. Phenomena, in general however, are slower in the ocean than in the air.

The differences in the earth's two major fluid environments are mainly dependent on the fact that one is a gas and one a liquid. Ocean has many properties similar to water, but it is the presence of salt that makes the ocean what it is. Its major properties are a function of: temperatures ranging from —2° to 30° pressure, from zero to 10,000 db (a decibar equals 1.5 psi, one tenth atmosphere, and is the pressure increase per meter of depth); and salinity, 33 to 40 per cent.

Some physical properties of water are unique and apply generally to the ocean. Heat capacity, latent heat of fusion, latent heat of evaporation, surface tension, dielectric constant and heat conductivity of pure water are the highest for any fluid. However, the dielectric constant of sea water, because of dissolved salts, is obviously relatively low. Water also has good transparency and good dissolving power.

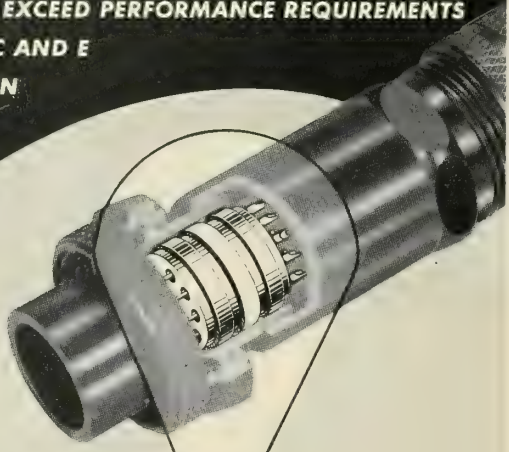
Circulation affects a number of the ocean's properties to a considerable degree, such as the distribution and concentration of suspended matter, chemical contents, organisms, transparency, eddy diffusivity, conductivity, etc. Independent of motion are: specific heat, osmotic pressure and density.



Electromagetic energy, generally speaking, finds the ocean is not its medium, though the strength of the earth's magnetic field remains unaltered. Infrared rays are 99 per cent in less than a meter. Of all electromagnetic energy most is reflected; the rest is quickly absorbed, with blues and yellows penetrating the deepest. These have been detected down to about 1000 feet.

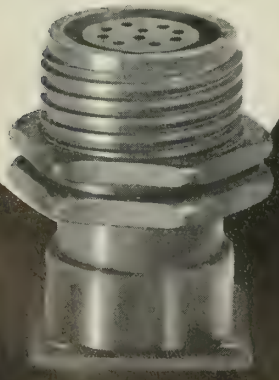
The acoustic properties of the ocean are relatively good, being a function of temperature, pressure and salinity. Thermal radiation is poor due to high heat capacity and low thermal conductivity.

In terms of weapons systems, efficiency of radar is poor (to a point of complete uselessness); propulsion is relatively poor; acoustic devices work well; blast transmissibility is excellent; so is concealment, if silence is maintained.



Elsewhere in this issue, hydrodynamics is called the art of silence. The first effort of every submarine and underwater missile designer is to get greater performance with no noise. The characteristics of water that result in noise generally also retard speed, increase drag. The biggest of these is cavitation—a pecularity of a fluid.

A break-away of the medium from the surface of a body passing through the medium occurs when the pressure drops below the vapor pressure of the medium. In simple terms bubbles appear on the skin. Not only do they



Top diagram shows beam pattern and divergence of sonar ping. Below this same ping is refracted by changing density of the water, giving false impression of target location.

Chart of basic thermal structure of the ocean (typical midwinter conditions in mid-latitudes) shows sharply changing temperature.

reduce the efficiency of a propeller, for example, but when they collapse they do so explosively and make a racket. This phenomenon is basically similar to going from laminar to turbulent boundary layers in aeronautics. Perhaps the biggest underwater design objective is the development of high-speed, cavitation-free underwater flight.

But man isn't the only one to make noise underwater. Fish and their other underwater cousins are quite a vocal lot, and the noise they make doesn't help man's effort to detect, guide and communicate acoustically.

The speed at which sound travels underwater depends mainly on the water's density. This varies primarily with temperature and salinity. The variations are many, local and changing. Sound refracts in changing density. Thus, a target may appear to be in one direction but may actually be in another. These are just a few of the problems facing underwater missile designers.

Yet nature appears to have few of these problems. Fish swim at high speeds and don't cavitate. They travel great distances without any navigation problems. They maneuver rapidly and intricately en masse in complete unison, obviously having a highly efficient communications system all their own. The south Atlantic's diving petrel literally flies into the water and continues to fly underwater with his wings with complete ease—transitional missilemen take note!

So, that these things are possible is, in a way, proven. It only remains for man to discover the way.★

Model PZ-14

Model PZ-6

Kistler SLM Transducers measure combustion, detonation, hydraulic and pneumatic pressures precisely

Featuring extreme ruggedness, high sensitivity and fast response, the precision, Swiss-made SLM Pressure Transducers permit direct measurements of *pressure* and *rate* of pressure changes.

Providing continuous operation at steady temperatures up to 600° F, with intermittent gas temperatures on the diaphragm to above 3000° F, they give faithful response to fast or slow pressure variations in shock tubes, gun tubes, rocket motors, rocket sleds, aerodynamic models, gas turbines, diesel and gasoline engines, compressors, fuel pumps, hydraulic and pneumatic control systems.

Calibration is constant and practically independent of temperature. This is the only commercially available crystal type instrument that can be calibrated by conventional static methods.

Pressure changes generating an electrical charge in the pickup are measured by an electrostatic type Kistler amplifier and displayed on an oscilloscope. Voltage signals are about 1000 times higher than from a typical strain gage or inductive type instrument. The standard Model PZ-14 Transducer covers all pressure ranges from 0.1 psi to 3000 psi and measures full vacuum. A Kistler pickup adaptor extends this range to 30,000 psi. Response time is 15 microseconds, resolution .01 psi with linearity and repeatability better than 1% of the pressure being measured. Designed for relatively "hard-to-get-at" locations, the Sub-Miniature Model PZ-6 Transducer achieves response times to one microsecond. A new electrostatic feedback amplifier is available for use with this type pickup.

The SLM Pressure Pickup, combined with special low-noise cables and a Kistler Piezo-Calibrator-Amplifier (required to couple pickups to oscilloscopes or recorders) constitutes the Kistler SLM Pressure Indicator. For complete information, request Bulletins PI-114, PZ-14 and PZ-6.

Space Medicine

by Hubertus Strughold, M. D.

For the first time, *space medicine* appears as a topic in the columns of m/r. *Space medicine* is a branch or an extension of *aviation medicine* which started some forty years ago. *Aviation medicine,* now an officially recognized specialty of medicine—studies the human factors involved in atmospheric flight. In contrast, *space medicine* studies the human factors in flights outside the atmosphere or in space flight.

From a medical point of view, outside the atmosphere is considered beyond the functional borders of the atmosphere which are found in the upper atmosphere and some even within the stratosphere. The cessation of the various atmospheric functions indicate that the larger portion of the atmosphere is partially or totally *space equivalent.*

The concepts of the atmosphere's functional borders and space equivalence within the atmosphere, both developed in *space medicine,* have removed the fictional connotation from space flight and have brought it to a down-to-earth reality. Therefore, *space medicine* studies not only the human factors involved in satellite flight, lunar operations, and interplanetary space travel, it concentrates its special attention upon *space equivalent* flight operations. The record flight of Capt. Iven C. Kincheloe in October 1956 was a space equivalent flight—to a very high degree.

Scope of *space medicine* also includes the study of ecological conditions on other planets, particularly atmospheric conditions. This field is called planetary ecology or more generally, *astrobiology.*

In 1949 Maj. Gen. Harry G. Armstrong created the Department of Space Medicine at the School of Aviation Medicine USAF, Randolph Air Force Base, Tex., to study the human factors involved in space flight.

At about the same time the Aeromedical Laboratory at Wright-Patterson AFB, Ohio, began preparations for animal studies in rockets. Since 1952 the Air Force has had a Space Biological Branch at the Aeromedical Field Laboratory at Holloman Air Force Base.

A decisive start into future human space flight was made in 1951 at the Symposium on the Physics and Medicine of the Upper Atmosphere, in San Antonio, Tex. The symposium was organized by Maj. Gen. Otis O. Benson, Commandant of the U.S.A.F's School of Aviation Medicine at Randolph Air Force Base, Tex. and Clayton S. White, M. D., Research Director of the Lovelace Foundation, Albuquerque, N. M.

At the 1951 annual meeting of the Aeromedical Association, a space medicine branch was founded. Each year it offers a special session at these meetings. Many space medicine meetings have been held since.

By action of the Board of Directors of the American Rocket Society, at its 1957 Spring Meeting, a new technical division was created, known as the Human Factors Division. Included in its purlieu are *space medicine* and *human engineering.*

It is apparent the field of *space medicine* is off to a solid start and an unlimited future.

Next meeting is the Symposium on the "The Age of Space," sponsored by the Southern Research Institute, Birmingham, Ala. It will feature a visit on May 16-17 to the Redstone Arsenal at Huntsville, Alabama. *Space medicine* will be the subject of the paper by the Surgeon General of the United States Air Force, Maj. Gen. Dan C. Ogle.

This and other *space medicine* conferences will receive thorough coverage by m/r in general and in this column in particular.

international briefs

Russians Set Up Czech Missile Bases

The Soviet Union has established eight missile launching bases in Czechoslovakia according to the London Daily Telegraph.

One base is near Olomouc, Moravia. North of the Olsany Highway, an area of 500 acres has been enclosed since October. There are other sites about 10 miles west and slightly south of Zwittau, at Valasske Klobouky in Western Slovakia, near Tabor, and southwest of Strakonice. These have been completed.

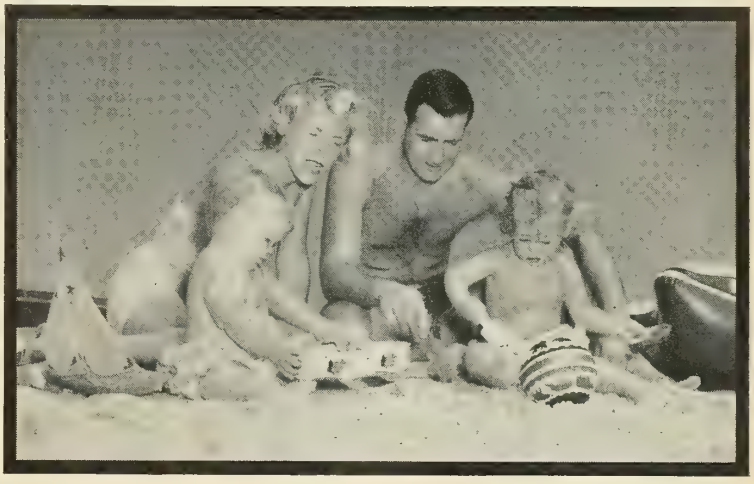
Three other bases are understood to be under construction. One is 10 miles east of Pilsen, another 30 miles almost directly south of it, and a third slightly west of Litomerice.

The Litomerice site is reported to have been planned for eight rocket launchers. It is the largest.

The others appear to be about half the size. All the sites have their own anti-aircraft defense, radar installations and flight strips in the vicinity.

In none has rocket launching equipment yet been installed. But more than a dozen mobile air defense rocket launchers have already been shipped from Russia into Czchoslovakia.

It is believed that the rockets, or other missiles, for which the sites are designed will have ranges of 120, 360 and 480 miles and will be able to reach into West Germany, Austria and Italy.



It is reliably reported that in Smichov, southwest of Prague, a Russian training school for rocket technique has been established. It is said to be headed by Lt.-Gen. Pomarev, a Russian technical expert.

Swedes Get *Jindivik* Missile

First deliveries of a batch of Australian-built *Jindivik* pilotless target airplanes have been made to the Royal Swedish Air Force. The *Jindivik* will be used in Sweden for missile firing tests. It is considered by Swedish experts as the best design now available for this purpose. Sweden is understood to have bought ten *Jindiviks* at a cost of $1,200,000 as an initial order. Meanwhile, at the end of last month the Swedish Navy announced that it has fired the first Swedish naval missile—from the destroyer *Halland*. It will be used for naval artillery purposes.

Engineers:

Stimulating work . . . Stimulating play just minutes apart

This is Honeywell in Minneapolis . . . an ideal atmosphere for the engineering mind. At work; outstanding technical facilities plus the opportunity to work on today's most advanced electronic projects, a chance to work in a small group, guide your own project, get the recognition you deserve.

And in Minneapolis, just minutes from your work, 22 lakes and 151 natural parks. Swimming, fishing, boating . . . year-round outdoor play for you and your family, good schools, theatres and shopping, too!

At Honeywell you move ahead quickly. This fast growing company, already world leader in automatic controls, has more than doubled sales in the last five years, increased its engineering force over 100%. In such a company, promotions open quickly. At Honeywell, they come *from within*. You start at a first-rate salary and it's *just the start*.

ENGINEERS, SCIENTISTS:

What did they say the last time you had an

IDEA?

At Decision, we talk to hundreds of engineers, and many report how frustrating it is when they make a good constructive suggestion and are gently reminded that "ideas" are the responsibility of others. (Strangely enough, these same companies often talk about "creative engineering" in their recruiting ads.) Fortunately this attitude is not typical of most progressive companies today.

We know many companies who encourage and appreciate creative thinking . . . who know that youth, inspiration and progress all go together.

Whether you're thinking seriously about changing jobs or not, Decision can improve your job perspective *confidentially* and at no cost to you. We will send reproductions of your resume (without your name) to the hundreds of top ranking firms—our clients—who pay us to find good men. And, we will enter your name and resume in our unique Decision/Register, which we search daily to find engineers for specific job openings.

World Astronautics

By Frederick C. Durant III

In Germany the world's first rocket society came into being thirty years ago. In less than fifteen years rocket technology evolved from an art to a practical science. The A-4 (or V-2) still stands as a monument to ingenuity and determination.

In early post war years strong anti-militaristic feeling dominated all activities of the reborn society, Gesellschaft für Weltraumforschung. However, the society kept abreast technically with rocket developments abroad and extrapolated data for ambitious space flight programs.

Recently, the society has been renamed: Deutsche Gesellschaft für Raketentechnik und Raumfahrt to indicate increased interest in rocket technology. In addition to their journal, WELTRAUMFAHRT, members will receive a new technical journal to be published entitled: RAKETENTECHNIK UND RAUMFAHRTFORSCHUNG. For those rocket engineers and laymen who read German, membership is a bargain; about $6.25.

In Bremen, the Arbeitsgemeinschaft für Raketentechnik is designing, in addition to the "oil-spray" rockets (m/r April '57, pg. 88), a static test stand, a liquid propellant motor, a hybrid (solid-liquid) motor and an inexpensive multi-staged sounding rocket.

In Stuttgart, Dr. Ing. Eugen Sänger and his mathematician wife, Dr. Irène Sänger-Bredt, head a small study group at the Forschungsinstitut für Physik der Strahlantriebe e.V. Stuttgart which has developed a hot-water RATO unit. But the major production of the FPS has been outstanding papers in ramjet combustion equilibria calculations and ultra-advanced treatises on atomic and photonic rockets. The Sängers, it will be remembered, authored the famous hypersonic rocket-powered globe-circling "skip-bomber" study in 1944.

At a number of universities excellent graduate and post graduate research is being carried out in a number of related fields. Some of this work is under USAF contract.

In the background, reported only through rumor, are indications of interest by the Army and industry. There is natural hesitation but short range anti-tank and anti-aircraft missiles are considered a safe bet to be under development.

•

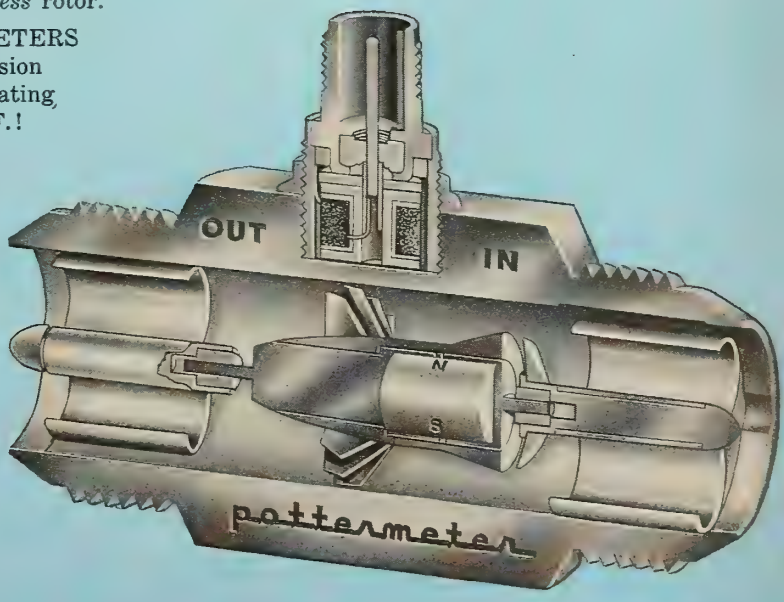
Twelve official station sites have been picked by the Smithsonian Astrophysical Observatory for optical tracking of the earth satellites. Only two of the sites are on U.S. soil (White Sands Proving Ground and West Palm Beach). Surprisingly, just one of these stations is to be shared jointly with the official NRL Minitrack program; this site is in Australia.

The first station to be ready will be at White Sands this August. The next will be the important one in South Africa which will first see the satellite appearing out of the northeast from Florida about 30 minutes after launching. The rest of the stations will be activated every 2—4 weeks as the specially designed super-Schmidt cameras and crystal clocks are delivered and checked out. Station operators will be trained at White Sands. It is expected that with good weather, the optical tracking stations will be kept busy throughout the IGY. The Minitrack stations will have little to do after the two-week—duration batteries in the satellites have ended their transmissions.

•

In a radio interview broadcast beamed at Western Europe, Russian scientist Anatoly Blagonravov has concluded that man will suffer no physical consequences from flight into space. These conclusions were based upon data from six years of experimentation with dogs carried aloft in sounding rockets.

COCKTAILS FOR ROCKETS



Hydrazine

Lox

Well blended! Rockets are meticulous drinkers. They like their liquids mixed in precise proportions. That's why in missile and rocket ground testing and airborne telemetering, Potter Electronic Flowmetering Systems have become standard equipment. The POTTERMETER is the only flowmeter which features the hydraulically positioned, *bearingless* rotor.

For more than 15 years, POTTERMETERS have been successfully used for precision measurement of continuous and pulsating flow of fluids from –455°F. to 1000°F.!

The Johns Hopkins University
Applied Physics Laboratory

ANNOUNCES

. . . important openings on our guided missile research and development staff for men who wish to identify themselves with an organization whose prime purpose is scientific advancement.

Because the Applied Physics Laboratory (APL) exists to make rapid strides in science and technology, staff members require and receive freedom to inquire, to experiment, to pursue tangential paths of thought. Such freedoms are responsible for findings that frequently touch off a chain reaction of creativity throughout the organization. As a staff member of APL you will be encouraged to determine your own goals and to set your own working schedule. You will also associate with leaders in many fields, all bent on solving problems of exceptional scope and complexity.

Equidistant between Baltimore, Md., and Washington, D. C., our new laboratory allows staff members to enjoy suburban or urban living and the rich cultural, educational and research facilities offered by both cities.

Openings Exist in
These Fields:

DEVELOPMENT: *Stability and control analysis; ramjet engine design; preliminary design and wind-tunnel testing; electronic guidance and control systems.*

RESEARCH: *Interference and heat transfer phenomena; internal aerodynamics; hypersonics, turbulence, shock wave phenomena, combustion.*

SEND NOW FOR OUR NEW 30-PAGE PUBLICATION DESCRIBING IN DETAIL THE SCOPE OF THE LABORATORY'S PROGRAMS AND THE UNIQUE ENVIRONMENT IN WHICH STAFF MEMBERS WORK AND LIVE.

International Scene

By Anthony Vandyk

The long-awaited confirmation has come that guided weapons are being included in the U.S. mutual aid program for the NATO nations in fiscal 1957. The missiles include the *Honest John* and *Matador* SSMs and the *Nike* SAM. These three models are already being used by U.S. forces in Europe. Which European nations will get which missiles and when? There has been no official answer but Dutch War Minister Staf stated last month that the *Honest John* is to be supplied to the Dutch Army and that personnel would soon go to Germany for training. The *Honest John* will replace the army's heavy artillery.

•

Britain's *Sea Slug* naval SAM now in the test stage is being built by two components of the giant Hawker Siddeley Group—Sir W. G. Armstrong Whitworth Aircraft Ltd., and Armstrong Siddeley Motors Ltd. Armstrong Whitworth is responsible for the airframe while Armstrong Siddeley is producing the rocket engine for the missile. The guidance system comes from a company outside the group, the General Electric Co. which has no connection whatsoever with the U.S. firm of that name.

•

Australia's first SAM unit will be established, Prime Minister Menzies disclosed at the same time as he announced the alignment of his nation's armaments with those of the U.S. Mobile control and reporting units will be established at Darwin and Perth, he revealed. An Australian defense mission will visit Washington in a few weeks to seek details of available short and medium-range missiles. It may also discuss the use by the U.S. of Australia's Woomera range for testing long-range American missiles.

•

British counterpart of North American's Santa Susana, Calif. rocket testing facility is an establishment in the north of England at Spadeadam, Cumberland. This desolately located test facility is being operated by Rolls-Royce Ltd. under contract to the Ministry of Supply. The engines to be tested there will be North American rocket units built under license by Rolls-Royce.

•

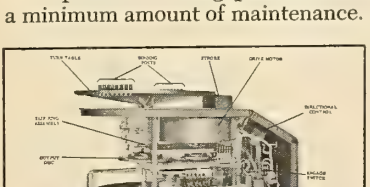
The Canadian government's guided missile program was the subject of brief baiting in the House of Commons recently. Opposition members asked Defense Minister Campney if any guided missiles "apart from the obsolete *Sparrow*" were to be made available to Canada by the U.S. He indicated that this was the case. There has been no official word from the Canadian government on the companies participating in the *Sparrow* license program, although Avro Aircraft and Canadair have both been given contracts for the development of a missiles system.

•

The de Havilland export organization is working on a program to enable the various DH companies to conserve the important position they have won since the war in the military export field. Much of de Havilland's bread and butter has come from the export of the Vampire, both the fighter and trainer versions, which is powered by a "house product"—the DH Goblin engine. It is hoped to replace Vampire exports with overseas sales of the highly efficient DH AAM which uses an infra-red guidance system developed by Mullard, British affiliate of the giant Dutch Philips electronics group.

Photo courtesy American Gyro Corporation

How to keep a missile on target



Genisco Rate-of-Turn Tables provide a fast, precise means of calibrating and evaluating rate gyros

It is imperative that components used in missile guidance systems perform to precise specifications. The Genisco Rate-of-Turn Table is a precision test machine used to calibrate and evaluate rate gyroscopes, vital components in missile guidance systems. Almost all major gyro manufacturers are now using these precision turntables in their test programs.

SMOOTH, CONSTANT ROTATION—Rotation of the table is infinitely-variable from 0.01° to 1200° per second. Constancy of angular velocity is within 0.1%, including drift and wow errors. This accuracy is due in large measure to a unique 60-cycle, 180 r.p.m. synchronous motor and a ball-disc integrator drive system. Absence of gears, belts, pulleys, etc., eliminates rotational irregularities inherent in gear-driven machines.

SPECIALLY SUITED FOR TESTING LARGE QUANTITIES—Operation of the machine is extremely simple. Precise rates can be set quickly and easily, using only a single hand-wheel, and without "hunting" or having to read complicated scales. These features enable inexperienced personnel to become proficient in the operation of the machine after a few minutes' instruction.

The machine is unusually rugged and operates for long periods with a minimum amount of maintenance.

Interior view of the Genisco Rate-of-Turn Table, Model C181, shows the neat, compact design. More than 100 of these precision machines are now in use.

Several instruments (total weight 100 lbs.) can be tested simultaneously without affecting accuracy.

LOW ELECTRICAL NOISE LEVEL—Sixteen slip rings in the machine provide electrical connections from the rotating objects to the control panel. Copper graphite brushes and coin silver slip rings reduce electrical and AC pickup noise below two millivolts per slip ring.

If your problem is development of a single laboratory prototype or production-line calibration and evaluation of rate gyros, write for complete technical data. Address your inquiry to: Contracts Manager, Genisco, Incorporated, 2233 Federal Avenue, Los Angeles 64, Calif.

Underwater Missile and Torpedo TEST EVALUATION

by Gilbert L. Maton
John I. Thompson & Co.

THE DETERMINATION of whether a developmental weapon possesses the required operational characteristics needed is largely based on evidence resulting from test. The fundamental procedure is to subject the proposed design to as rigorous a test program as possible. The results of this testing are then carefully scrutinized and appraised in light of tactical adequacy and technical practicality to determine whether the design is adequate, needs work, or is impractical.

Since the decision established from such evaluation is based on test data, it is intuitively apparent that the data accumulated from such testing must be reliable and useful. To best illustrate how this may be accomplished, it will help to review the scientific method or general experimental procedure which can be recognized as intrinsic to any test program. This method delineates that the planning and conduct of any experimentation follows a set step-by-step plan.

(1) A clear and unambiguous statement of the objective of the test is made.
(2) All available background information regarding the item to be tested is assembled and scrutinized.
(3) The specific test program is carefully planned.
(4) The test program is executed.
(5) The resulting data is assembled and analyzed.
(6) The analytical results are interpreted.
(7) The conclusions are reported.

In order to bring the importance of each step of this procedure into proper perspective, each of these steps and its specific application to torpedo testing and evaluation is discussed in some detail in the following paragraphs.

Test Objectives

A clear statement of the objective of the test in advance serves two purposes; (1) it defines the scope of the program and makes subsequent planning administratively practical, and (2) it meets the requirement of a valid conclusion that the objective be stated without reference to the result.

The general objective of an underwater missile and torpedo test is largely influenced by the development stage of the weapon. The evolution of the weapons system can be divided into distinct phases: Formulative; Planning; Research; Experimental; Design, Production Engineering; Pilot Production; Full Production.

The formulative phase is devoted to establishing the operational requirements of the weapon. As a background, it is probable that the requirements arise from the planning and operating elements of the military service. Occassionally they may come from a technical agency or laboratory in which a well known operational problem is examined from the viewpoint of a specialized science. In any case, these requirements represent the basic purpose and need for an improved weapon.

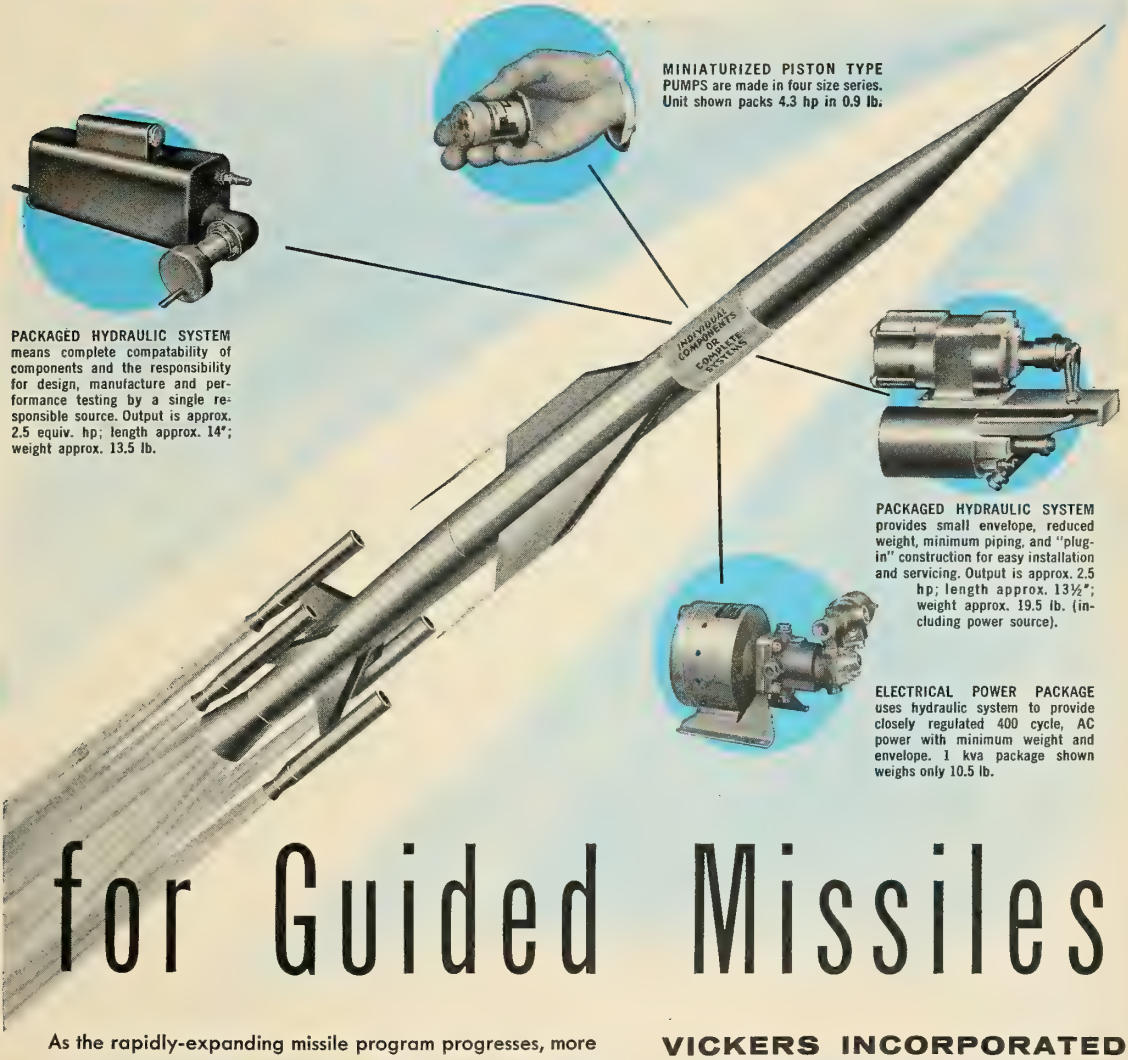
The planning phase is used to establish the objectives of the program in light of time and economic considerations. The organizational structure is delineated and the basic scope of the program is outlined. It is mainly an administrative control period.

The research phase is concerned with "filling in gaps" in existing fields of knowledge. In general, it is a measurements program of experimental elements and components having unknown features in order to determine the practicality of meeting the operational requirements of the weapon. The measurements program is planned and scheduled to support the selection of specific design parameters which are incorporated into a design specification.

The experimental phase is the most complex and critical in the developmental program. It is mainly concerned with demonstrating the workability or sufficiency of a proposed design. The consecutive steps of this phase may be outlined as follows:

(1) Integration of the design by sketch
(2) Layouts (on paper)
(3) Details (on paper)
(4) Parts fabrication
(5) Assembly and adjustment of parts
(6) Adjustment of assembly and corrections
(7) Tentative investigation and dynamic tests

The design phase of the program consists of the same general steps as the experimental phase. The purpose of this phase is to provide a number of similar models for use in the rigorous technical evaluation which concludes the phase. This evaluation is a dynamic test which subjects the "service test" models to realistic exercises which closely duplicate the requirements imposed by the operational application of the weapon rather than to any arbitrary or indirect standards of a laboratory.



It is not unusual for the first few steps of this phase to be repeated many times. Eventually, however, a number of supposedly identical units, or service test models, are available for technical evaluation.

The production engineering phase may be combined in some cases with the design phase previously described. However, scrutiny of the program will invariably enable them to be differentiated. In a sense it is an analytical phase, since it is mainly concerned with analyzing *if* and *how* manufacturing operations influence the design. Three viewpoints are involved, with the designer, the manufacturer, and the military service (user) each contributing a facet to the analysis.

A developmental production lot of the item is manufactured in accordance with preliminary production techniques, and using preliminary tools, jigs, and fixtures. These developmental models are used in product demonstration tests and operational evaluation tests. The former determines if production tech-

The author has drawn freely on the substance of reports prepared under U.S. Navy Bureau of Ordnance contracts with John I. Thompson & Co. for studies, design of experiments, and evaluation of developmental torpedo testing. Procedures outlined are the author's own, however, and may not be construed as constituting the Bureau's official procedures.

VICKERS® HYDRAULICS

MINIATURIZED PISTON TYPE PUMPS are made in four size series. Unit shown packs 4.3 hp in 0.9 lb.

PACKAGED HYDRAULIC SYSTEM means complete compatability of components and the responsibility for design, manufacture and performance testing by a single responsible source. Output is approx. 2.5 equiv. hp; length approx. 14"; weight approx. 13.5 lb.

PACKAGED HYDRAULIC SYSTEM provides small envelope, reduced weight, minimum piping, and "plug-in" construction for easy installation and servicing. Output is approx. 2.5 hp; length approx. 13½"; weight approx. 19.5 lb. (including power source).

ELECTRICAL POWER PACKAGE uses hydraulic system to provide closely regulated 400 cycle, AC power with minimum weight and envelope. 1 kva package shown weighs only 10.5 lb.

for Guided Missiles

As the rapidly-expanding missile program progresses, more and more applications are being found where Vickers Hydraulics will be used to advantage. Vickers has miniaturized components that can be integrated into system packages with minimum tubing . . . manifolding components gives no opportunity for leakage. These "packaged" systems with their optimum performance and *reliability* are used to power missile control surfaces. Minimum space and weight, easy installation and servicing are other important advantages. Get in touch with the nearest office listed at the right for further information.

niques have affected performance in any way; the latter ascertains the operational characteristics of the weapon and represents the final test action of the phase.

The pilot production phase is devoted to smoothing out any remaining production problems. A prototype production lot is manufactured at this time, and these prototype models are used for familiarization and type tests. In addition, the preliminary proofing procedures for production lot units are determined and documented.

The full production phase is concerned with the quantity production of the design in its final form. The manufacture and all detailed steps of assembly and inspection are dictated by the outcome of all previous evaluations and uses of the weapon.

The chart illustrates this fundamental phase concept of a developmental program by outlining the general configuration of developmental effort previously discussed.

Although conscious separation of phases is shown with a constant progress in one direction, phase combinations and reversals must be appropriately considered in actual cases. It must also be recognized that the degree of overlap between phases may vary. This imbrication is more noticeable in cases where the ultimate manufacturer is chosen at the start of the development.

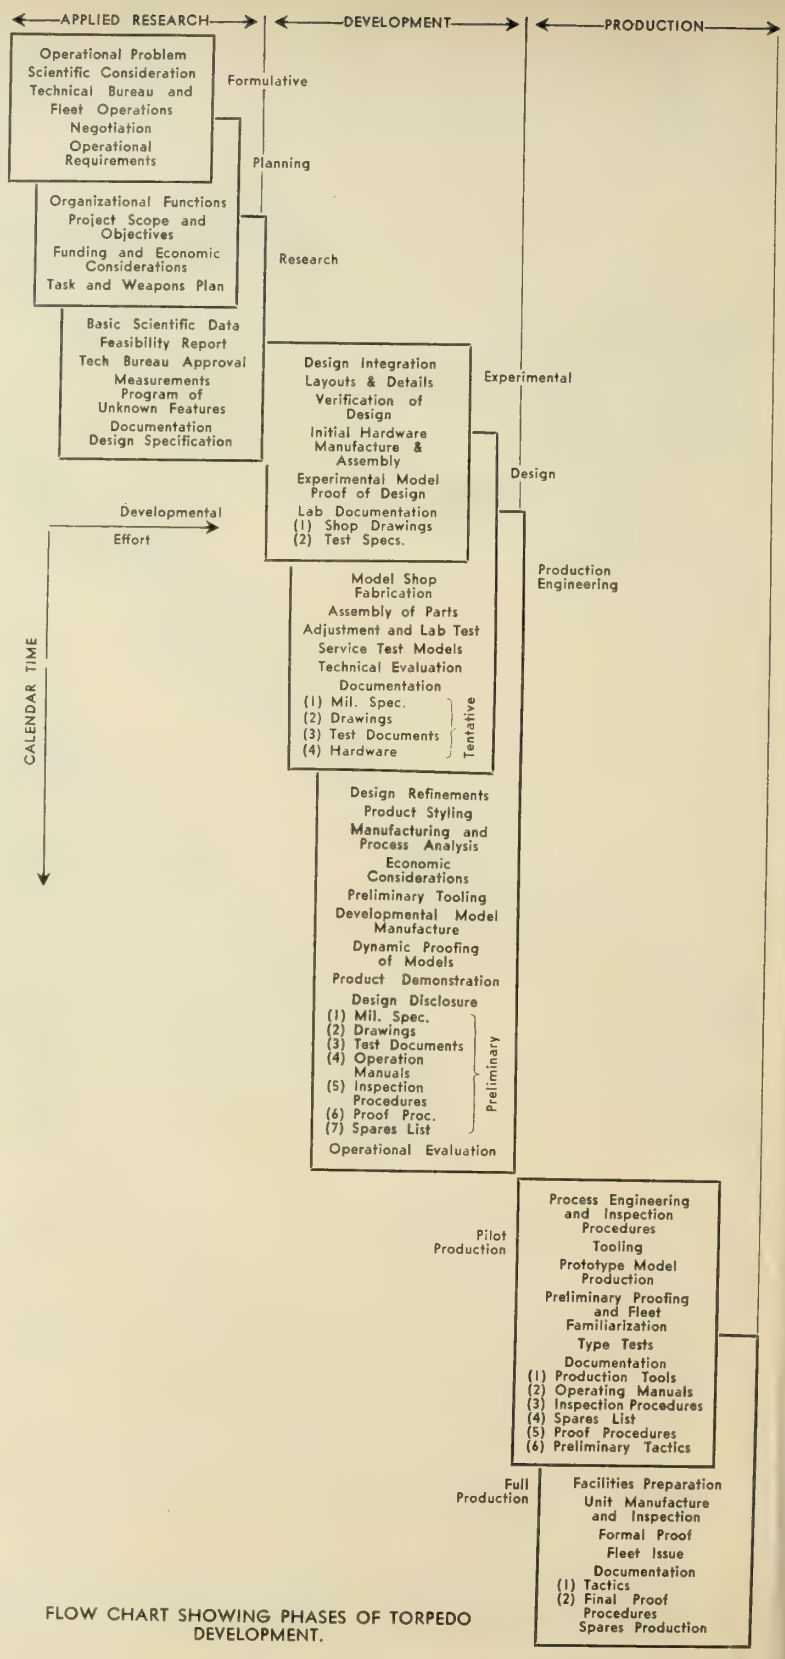
Of the phases discussed, the research, experimental, design, and production engineering phases are of primary interest because they represent the main portion of the developmental program in which some manner of physical testing of the proposed weapon is done. The general test objective of each of these phases may be defined as follows:

Research:

To determine if the basic design idea shows promise as a solution to the operational requirement.

Experimental:

To determine if the design idea can be incorporated into a device to fill the technical requirements.



Design:

To determine if the mechanically (technically) configured design will provide a satisfactory solution to the operational requirements.

Production Engineering:

To determine the compatibility of the design to manufacturing techniques and to establish the basic operational characteristics of the design.

A sound scientific approach to a test calls for the general objective to be more explicitly delineated than outlined in the preceding paragraph. If this is not done, analyzing personnel may be confronted with the task of determining

FLOW CHART SHOWING PHASES OF TORPEDO DEVELOPMENT.

from the test criteria just what the original test objectives were. In view of the extremely high cost of developmental testing and the possible universal expenditure of the test units it is apparent that the omission of this initial consideration can seriously jeopardize the success of any test program.

Test Background Information

This step in experimental procedure involves collecting all existing information relating to the test objective from the best available sources. Tabulation of pertinent data from earlier testing work on the item has three specific advantages:

(1) It avoids the necessity of repeating work previously done

(2) It increases the certainty with which the new test may be planned and may reduce substantially the work required to disclose new facts

(3) It reduces the tendency to take calculated risks in the planning which would be based on engineering intuition rather than known facts.

During development, nearly every torpedo produced is in several ways different from torpedoes of the same group. Most units assembled in the experimental and design phases are handmade by highly trained engineers and technicians. Each man concerned in the fabrication of a model is, by his training and experience, competent to devise appropriate functional tests to check and adjust the assembly after each step in the construction of the unit. These tests are seldom written, and two equally competent men are not likely to devise and perform tests which are identical in conduct or precision. Since the tests and adjustments are often duplicated by different men and frequently at entirely different activities, it is desirable—even necessary—from the standpoint of getting useful and comparable data for analysis to document and standardize such test procedures as early as possible.

The test design step involves planning of specific details of the program in light of the test objectives. As such, it is concerned with the planning, control, conduct, analysis, and interpretive aspects of the test, rather than the specific test origin alone. In a broad sense, this step is the most crucial of those in the testing procedure since the selection of a test design imposes a selection of the possible methods of analyzing the results, and this, in turn, dictates the entire interpretive function.

The planning of a specific test design consists of four basic steps:

(1) Compilation of all test variables

(2) Compilation of all test criteria

(3) Experimental test design in preliminary form

(4) Review and revision of the design in light of analytical techniques and possible results.

Test variables are all the environmental and operational factors which might possibly affect the test results, including factors which can be controlled and those which cannot. Test criteria are the data which translate general test objectives into objectives involving measurable quantities. This requires that the background information of the weapon be analyzed to determine which parameters can most validly provide data which will verify the test objectives.

The experimental design, itself, incorporates the test criteria with particular selections of the controllable operating and environmental factors into a comprehensive test. A multitude of possible combinations of factors and criteria is possible, but a single "optimum" design is generally not possible for at least three reasons: (1) the analytical problem posed may be extremely complex; (2) the complete solution may involve parameters which are not economically measurable; and (3) the time to formulate and determine the "optimum" design is not always available.

The most practical approach to the test design problem is to select an experimental design from a family of "good" ones; that is, designs which have desirable characteristics with respect to the particular test. One such class of designs has been given the name "factoral" designs. A second class is "latin square" designs. Such general designs must be examined to establish specific applicability to the test under consideration and the class exhibiting the most favorable characteristics selected.

Test Conduct

This step of scientific testing procedure requires little explanation. It should be emphasized, though, that an orderly and conservative approach is essential. This especially applies to the taking of measurements and collecting of data where every precaution must be taken to assure that valid, unbiased, and accurate results are obtained. These precautions may be most properly assured if a systematic and inclusive schedule, spelling out clearly each test step to be followed, is prepared prior to conducting the test.

Test Reports

This step of the testing procedure requires that the test performed be described clearly and with full explanation of the background and pertinence of the problem and the meaning of the results. In all testing work, whatever the details of the method, it is essential that another person or activity be able to repeat the test and check what has been done or observed. Despite the authority or convictions upon which they rest, conclusions are of questionable value unless they can be verified.

Although much could be said concerning specific report content and arrangement, it seems sufficient to say that report preparation should be viewed in terms of three objectives:

(1) Conclusions should be limited to an objective summary of the evidence so the work recommends itself for prompt consideration and action.

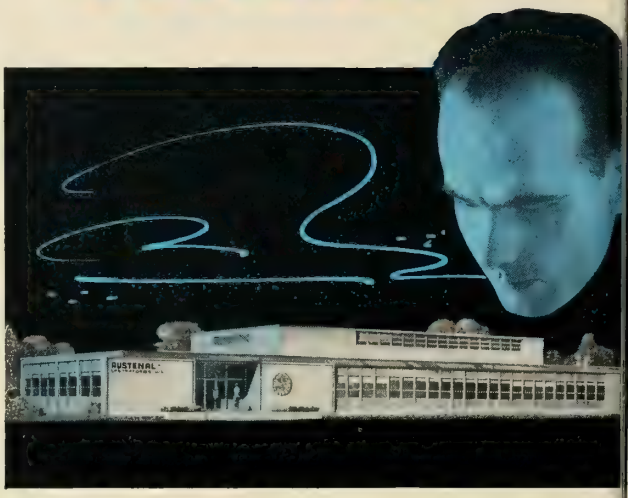
(2) Sufficient information should be supplied to permit the reader to verify the results and draw his own conclusions.

(3) Data should be presented in good form for future use.

All testing and evaluation reports should follow the same general form, tailored to the particular needs.

Test Data Analysis

This step in procedure represents the reduction of the recorded data into numerical form and application of proper mathematical and statistical techniques to the results. As mentioned previously, this step is not really a separate consideration, since it is so largely simultaneous to the test design step. Selection of test design imposes a selection of methods of analyzing the test results. It has been found that when a test program is run before the question of analyzing the results is examined, the result invariably is a low efficiency in information per observation.



Experience has also proven that the statistical approach to test design and test analysis is highly rewarding. This is particularly true in dynamic torpedo exercises where random variations in performance are of comparable magnitude to the effects to be established by a change in system parameter. In these cases, *statistical methods offer the only sound and logical means of analysis; there is no question of any alternative which is equally satisfactory.*

Test Result Interpretation

This step concerns correlating test results with initial test objectives. It cannot be too strongly emphasized that any numerical analysis of test data is only a convenient way of detecting and separating the effects of varied factors. The process of interpreting the results, that is, of telling administrative and management personnel what conclusions can be drawn or what should be done next, is by no means automatic. The process requires that personnel who interpret the statistical computations have a thorough knowledge of mathematical techniques and a clear understanding of the technical and tactical aspects of the weapon.★

design with austenal in min

New **microcast** *Research Facilities will incre investment casting applications and give design engineers greater latitude in planning parts.*

A new facility for advanced research is now under constructio Austenal to broaden the many applications of Microcast—to make methods and alloys available, and to allow greater freedom and lat in part designing.

One section of this new plant will contain the equipment familiar t investment casting industry and in addition, equipment necessary investigating numerous other methods of making and treating cast Adjoining the foundry area will be shops for pilot line and experim work in mold making, waxing, investing and finishing. There will b area containing laboratories for mechanical testing, physical te metallographic investigations, refractories development and che investigations.

Contact your Austenal engineer today and ask him to show you Austenal's continuing program of research and development will you design greater performance and reliability into the invest castings you require.

- - - It's **NEW** *from Austenal*

"Design with Microcast in Mind," Austenal's new informative booklet, tells you how to get the greatest benefit from Microcast, showing the great latitude of design possibilities, alloys available and a great deal more, valuable information. Write for it today.

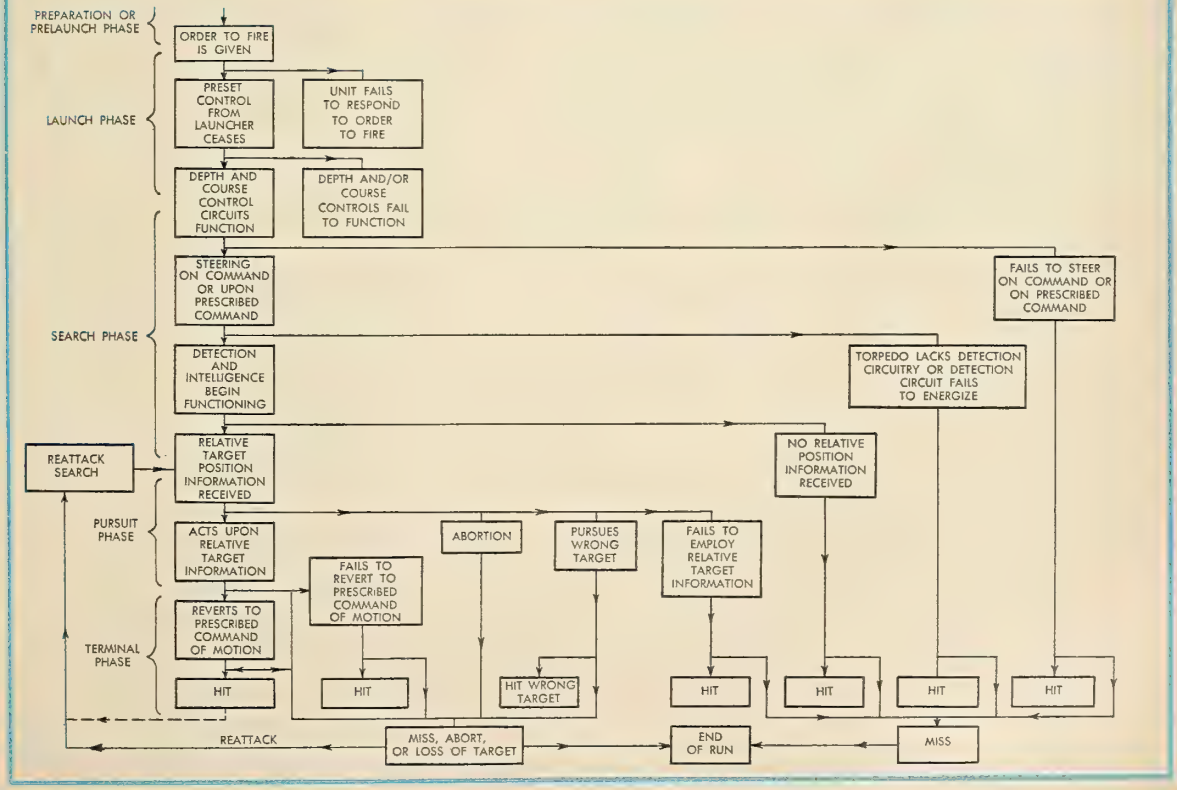
Torpedo Terms and Terminology

Underwater Missile Glossary

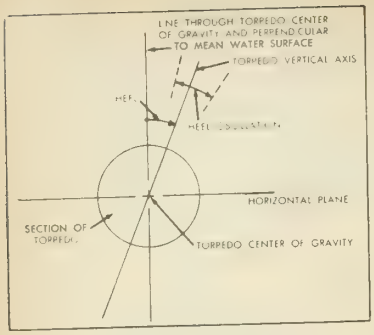
THE RAPID PROGRESS of torpedo development in recent years has brought with it a flood of terms. In many cases differentiation in the meanings has not been clear: different terms were found to have identical definitions; terms were so specialized that they had little general usefulness in torpedo development and evaluation programs; or a single term might be used to denote two or more different things. Up to this time, there has been no common basis for terms used.

The Bureau of Ordnance felt that because the program was carried out by many separate facilities and contractors, standard language would improve the ease and accuracy with which torpedo information could be exchanged.

In compiling a glossary of torpedo terms, John I. Thompson & Co., under the auspices of BuOrd, reviewed more than 100 reports and applicable documents. This material reviewed covered almost all current advance undersea-weapons programs, as well as some of the related science of guided missiles. The following is a digest of this glossary.

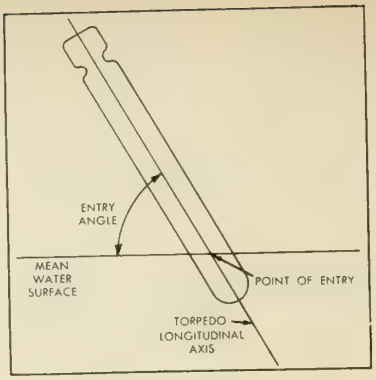


Two types of terms normally associated with *time* in a torpedo exercise are (1) terms that define the unique *instant* of a specific action or event and (2) terms that refer to the *interval,* or period, of time between two such actions. The latter terms are, of course, dictated by and subordinate to the former.



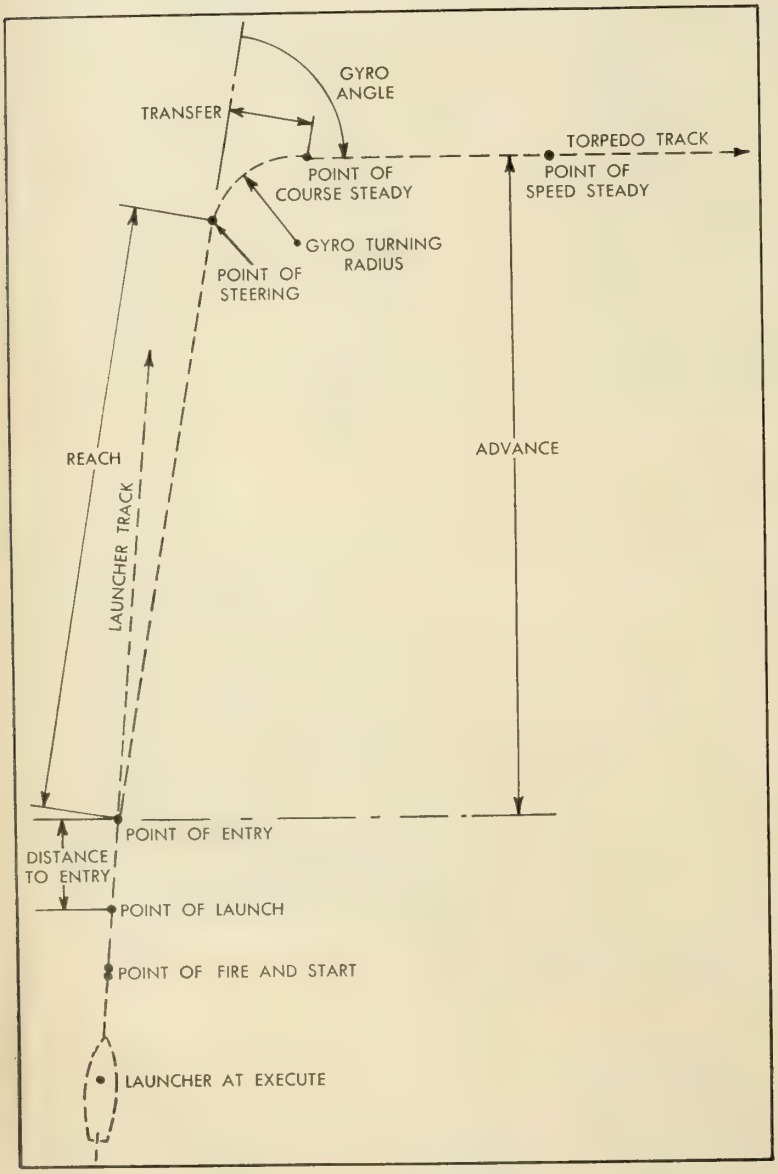
The sequential history of a general torpedo run divides logically into at least six distinct phases: (1) the preparation phase, (2) the launch phase, (3) the search phase, (4) the adquisitive phase, (5) the pursuit phase, (6) the terminal phase. A seventh phase, reattack, may exist under certain circumstances and for certain torpedoes.

The simplest torpedo has depth and direction (gyro) senses. The more complex torpedo can sense in some manner the presence of the target. A basic analysis of these relationships should be made in terms of the relatively new science of cybernetics. Such an analysis was beyond the scope of the present compilation.



The study on which this glossary is based discovered that terms currently used to describe the intelligence

Diagram of phases and actions of the torpedo run, arranged chronologically.



Rotation Terminology—Heel. (Some typical terms required to define rotation. Heel is designated as port or starboard.)

Rotation Terminology—Pitch.

Horizontal trajectory showing advance, distance to entry, gyro angle, gyro turning radius, reach and transfer.

characteristics of torpedoes have been generated more from the individual characteristics of particular torpedoes than from consideration of the fundamental cybernetics involved. It has not been possible to organize them into a system upon which a basic control language can be constructed. Consequently the terms defined largely represent only those in current usage.

Prior art has made the expression "acoustics" practically synonymous with intelligence, since development work has developed most rapidly in the field of acoustics. The terms listed in the glossary to define intelligence characteristics are, therefore, principally acoustic terms. This listing is not meant to preclude the use of analagous terms for other fields of development but simply reflects the fact that terms for other fields are not available for use at this time.

DEFINITIONS OF TERMS

Time Terms

READY. The instant that marks the completion of the preparation procedures for the exercise.

EXECUTE. The instant that marks the beginning of the torpedo exercise, normally considered zero time.

FIRE. The instant the verbal order to fire the torpedo is given.

START. The instant at which preset control from the launching vessel ceases.

LAUNCH. The instant the torpedo clears the launcher muzzle. For air or surface rack launchings, it is the instant the torpedo parts from the rack. In underwater launchings, launch marks the end of the launch phase.

ENTRY. The instant at which an air-launched or surface-launched torpedo strikes the water. For air-launched and surface-launched torpedoes, entry marks the end of the launch phase.

INSTANT OF STEERING. The instant at which the torpedo's direction controls become fully effective.

COURSE STEADY. The instant the torpedo is established on its preset gyro course.

DEPTH STEADY. The instant at which the torpedo is established at its preset depth.

SPEED STEADY. The instant at which the torpedo attains its constant running speed.

INSTANT OF ENABLING. The instant at which the torpedo becomes capable of making any control response to a detection.

INSTANT OF ARMING. The instant at which the firing device becomes fully capable of exploding the charge.

LOOK. The instant within a period of opportunity at which there is the maximum probability of target detection.

FLOOR REVERSAL. The instant at which the torpedo changes motion in depth search from down to up.

INSTANT OF DETECTION. The instant at which the stimulus of the target field becomes evident above the ambient field in the sensory system of the torpedo.

CEILING REVERSAL. The instant at which the torpedo changes motion in depth search from up to down.

INSTANT OF CONTACT. The instant at which the torpedo control mechanism first makes, in response to a detection, an action which would result in a change of direction of the torpedo.

INSTANT OF ACQUISITION. The instant at which the torpedo has completed accumulation of sufficient information to establish a trajectory which is compatible with its homing control law. Usually, three discreet points of the trajectory curve must have been established.

INSTANT OF ABORTION. The instant at which the torpedo, having lost its guidance information due to malfunction, initiates a new search phase.

INSTANT OF LOSS. The instant at which the torpedo, having lost its guidance information due to inherent limitations, initiates action for a new search phase.

INSTANT OF BLANKING. The instant when the torpedo reverts to memory control because external stimuli have saturated the sensing mechanism.

INSTANT OF HIT. The instant the torpedo physically strikes the target.

INSTANT OF MISS. The instant when the torpedo, in the terminal phase, passes the point of closest approach to the target.

RUN END. The instant the torpedo propulsion motor is shut down, generally signifies the end of the exercise.

Time Intervals

PREPARATION PHASE. The period between the time the torpedo test is first designed and start. The term has little significance as a descriptive expression of the exercise.

REACH TIME. The interval between start and instant of steering.

ADVANCE TIME. The interval between start and course steady.

TRANSIT TIME. The interval between start and depth steady.

PLUNGE TIME. The interval between start and speed steady.

TIME TO ENABLE. The interval between start and instant of enabling.

TIME TO ARM. The interval between start and instant of arming.

TIME TO 1ST (2ND, 3RD, ETC.) LOOK. The interval between start and the numbered look.

PERIOD OF OPPORTUNITY. The interval during which the target is continuously in the field of perception of the torpedo.

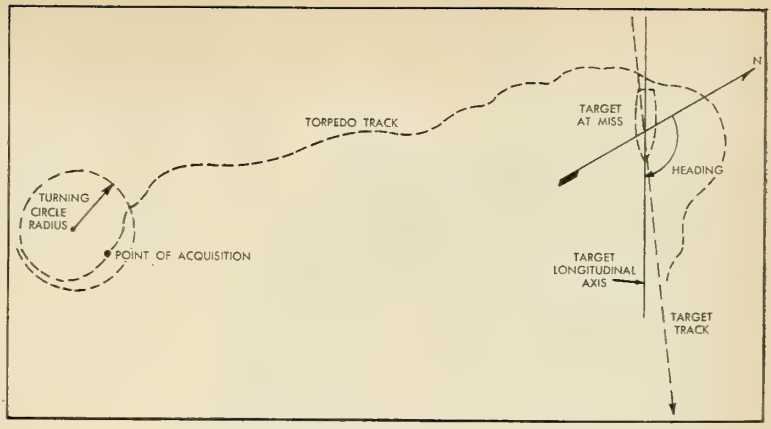
TIME TO 1ST (2ND, 3RD, ETC.) DETECTION. The interval between start and the numbered instant of detection.

TIME TO FLOOR REVERSAL. The interval between start and floor reversal.

TIME TO CEILING REVERSAL. The interval between start and ceiling reversal.

TIME TO 1ST (2ND, 3RD, ETC.) CONTACT The interval between start and the numbered instant of contact.

TIME TO 1ST (2ND, 3RD, ETC.) ACQUISITION. The interval between start and the numbered instant of acquisition or between miss and the number instant of acquisition.



ACQUISITIVE PHASE. The interval between instant of contact and instant of acquisition while the torpedo maintains continuous sensory contact with the target.

PURSUIT PHASE. The period during which the torpedo is maneuvering along its trajectory in response to its guidance information. It occurs between the instant of acquisition and the instant of abortion, loss, or blanking. Pursuit phases occurring during a reattack are designated "reattack" and are identified by an ordinal number (1st reattack pursuit phase, 2nd reattack pursuit phase, etc.)

PRELAUNCH PHASE. The period between execute or ready, whichever occurs first, and start.

PRELAUNCH WARM-UP TIME. The interval between the instant the electronic circuits are partially energized and start.

TIME TO FIRE. The interval between execute and fire.

Horizontal trajectory—heading, turning circle radius.

TIME TO START. The interval between fire and start.

LAUNCHING PHASE. The period between start and launch or between start and entry, whichever occurs last.

TIME TO LAUNCH. The interval between fire and launch.

SWIM-OUT TIME. The interval between start and launch for underwater launchings in which expulsion is accomplished solely by means of the propulsion mechanism of the torpedo.

AIR-TRAVEL TIME. The interval between launch and entry. The term applies for air and surface-launched torpedoes.

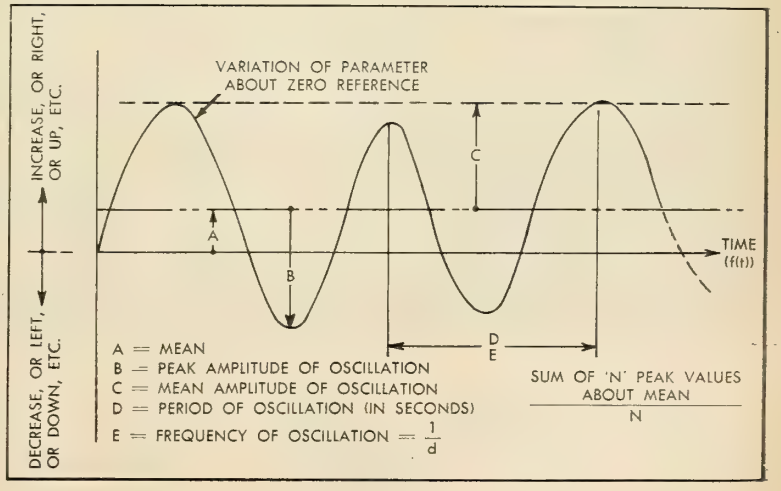
TIME TO ENTRY. The interval between start and entry.

ATTACK PHASE. The period of initial search, pursuit, and terminal phases of a run, or initial search and pursuit phase alone if no terminal phase exists.

SEARCH PHASE. The period during which the torpedo is maneuvering into position to receive information of relative target position. It occurs between launch and the instant of acquisition (underwater firings), entry and the instant of acquisition (air and surface firings), or miss and the instant of acquisition. Search phases occurring after a miss are designated "reattack" and are identified by an ordinal number (1st reattack search phase, 2nd reattack search phase, etc.).

TIME TO ABORTION. The interval between start and instant of abortion or between instant of miss and instant of abortion.

TIME TO LOSS. The interval between start and instant of loss or miss and loss.



TIME TO BLANKING. The interval between start and blanking or miss and instant of blanking.

TERMINAL PHASE. The period following the last effective target-position indication in which the torpedo holds by memory the established collision course. It occurs between instant of blanking and instant of hit or miss. Terminal phases occurring during a reattack are designated "reattack" and are identified by an ordinal number (1st reattack terminal phase, 2nd reattack terminal phase, etc.).

TIME TO HIT. The interval between start and instant of hit.

TIME TO (1ST, 2ND, 3RD, ETC.) MISS. The interval between start and instant of miss.

REATTACK PHASE. The period during which the torpedo, recognizing that it has missed the target, initiates a new search phase to relocate it and ends at instant of hit or miss. A reattack phase will normally consist of a reattack search, pursuit, and terminal phase. Reattack phases are usually identified by an ordinal number, as 1st reattack phase, 2nd reattack phase, etc.

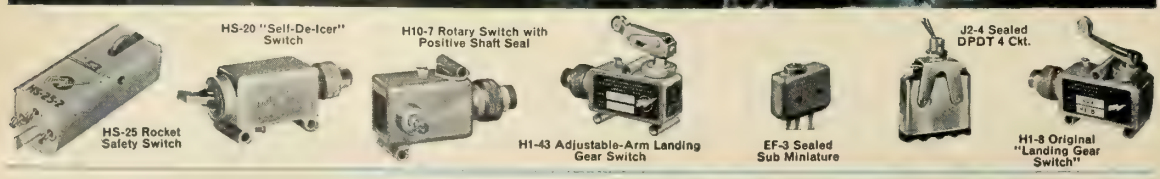
Time variation of motion.

ELECTRO-SNAP SWITCH & MFG. CO.

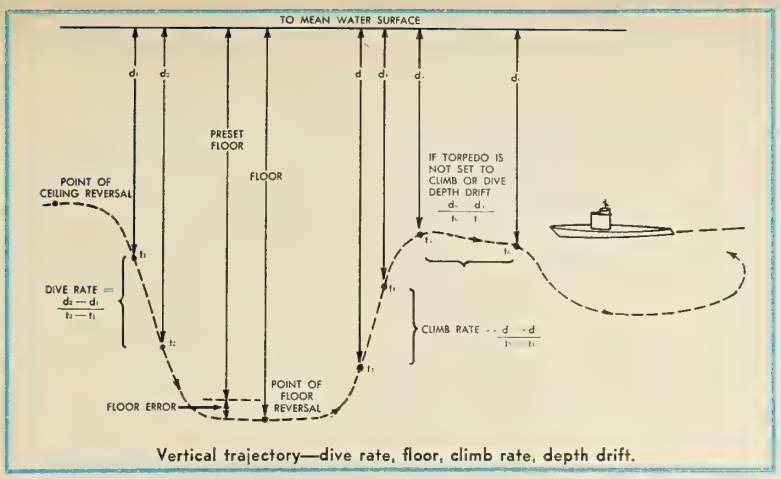
HE KNOWS

A pilot firmly prods a panel button: Wingtip tanks fall clear—or, perhaps, fire-choking fog explodes into a burning engine compartment. He *knows* what to expect and rely on, because a tough, tiny Electro-Snap aircraft switch is behind the panel.

Regardless of G-loading, temperature, speed, altitude, or weather conditions, Electro-Snap switches deliver a *known* performance for a *known* number of operations ...make certain of safe functioning for a predictable period of time.



This same predictability is built into every Electro-Snap switch—aircraft or industrial—though the jobs they do may not always be so critical. In any case, reliability is delivered with the minimum size, weight and cost consistent with the job requirements.



Electro-Snap "standard" switches are available for most requirements, and our engineered "specials" are solving many unique problems. If *you* have a switching problem, send it to us; our engineers will work with you closely in producing it *in any quantity* ...economically. THIS IS OUR ONLY BUSINESS!

SEND US YOUR SWITCHING PROBLEMS
and write for catalog details on our
standard switches...TODAY

ELECTRO-SNAP SWITCH & MFG. CO.

Chicago 24, Illinois

ELECTRO SNAP

Vertical trajectory—dive rate, floor, climb rate, depth drift.

RUN TIME. The interval between start and run end.

Position and Motion Terms

HEEL. The angle between the vertical axis and a line perpendicular to the mean water surface through the torpedo's center of gravity. Heel is designated as port or starboard.

PITCH. The angle between the torpedo's longitudinal axis and a line parallel to the mean water surface in the longitudinal-vertical plane of the torpedo. Pitch is designated as up or down.

YAW. The angle between the torpedo's longitudinal axis and the velocity vector in the longitudinal-lateral plane of the torpedo; port or starboard.

ROLL. Heel oscillation.

ENTRY ANGLE. The angle between the longitudinal axis of the torpedo and the mean water surface at the point of entry.

Trajectory Terms

TRACK. The line generated from point to point on the horizontal plane by the motion of the center of gravity of the vessel.

ADVANCE. The distance between the mean torpedo track following the point of course steady and a line paralleled to this track passing through the point of entry.

DISTANCE TO (ARM, ENABLE, CONTACT, ENTRY). The distance along the torpedo track between point of start and point of arm, enable, contact, or entry.

GYRO ANGLE. The angle between the intended (preset) torpedo track and the direction of launch.

GYRO TURNING RADIUS. The radius, in yards, of a theoretical circle through the arc described by the torpedo track from the point of steering to course steady.

REACH. The distance along the torpedo track between point of launch (underwater firing) or entry (surface or air firing) and the point of steering.

TRANSFER. The distance between a vertical plane through the torpedo's longitudinal axis at launch and a plane parallel to this plane through course steady.

COURSE. The angle measured clockwise from true north to the positive direction of the mean track of the vessel.

COURSE ERROR. The angle between the positive direction of the intended (present) mean track of the torpedo and the positive direction of the actual track.

RATE OF TURN. The mean angular rate with which the torpedo changes course during a specified interval.

HEADING. The angle measured clockwise from true north to the positive direction of the longitudinal axis of the vessel at any instant.

TURNING CIRCLE RADIUS. The radius of a circle maneuver of a torpedo.

PATH IN DEPTH. The line generated from point to point on the depth plane by the motion of the center of gravity of the torpedo or target, as designated (torpedo path in depth, target path in depth, etc.).

CLIMB ANGLE. The angle between the mean torpedo path in depth during a climb and a horizontal plane through the torpedo's center of gravity.

CEILING. The vertical distance between the mean water surface and the center of gravity of the torpedo at the point of ceiling reversal.

CEILING ERROR. The deviation between the preset or intended characteristic and the value observed.

DIVE ANGLE. The angle between the mean torpedo path in depth during a dive and a horizontal plane through the torpedo's center of gravity.

DIVE RATE. The rate of change of depth during a programmed dive.

FLOOR. The vertical distance between the mean water surface and the center of gravity of the torpedo at the point of floor reversal.

FLOOR ERROR. The deviation between the preset or intended characteristic and the value observed.

CLIMB RATE. The rate of change of depth during a programmed climb.

DEPTH DRIFT. The rate of change of depth error when the torpedo is not preset to dive or climb.

DEPTH CUT-OFF. The vertical distance from the mean water surface to the center of gravity of the torpedo at which the energy to the propulsion motor is automatically cut off.

Location

LAUNCHER (AT ARM, ENABLE, FIRE, ETC.) The instantaneous location of the center of gravity of the firing vessel projected upon the course or depth plane at the instant of arm, enable, fire, etc. Any time instant may be employed with this term.

TARGET (AT ARM, ENABLE, FIRE, ETC.) The instantaneous location of the center of gravity of the target projected upon the course or depth plane at the instant of arm, enable, fire, etc. Any time instant may be employed with this term.

RANGE. The distance, in yards, between the centers of gravity of the target and the reporting vehicle.

RELATIVE BEARING. The angle measured clockwise from the positive direction of the longitudinal axis of the reporting vehicle (launcher, target, or torpedo) to a straight line connecting it with the other vehicle concerned.

TRUE BEARING. The angle, measured clockwise from true north to a straight line connecting the reporting vehicle with the other vehicle concerned.

LAUNCHER DEPTH. The vertical distance from the center of gravity of the torpedo to the mean water surface at fire. Applies to underwater launcher only.

LAUNCHER HEIGHT. The vertical distance from the mean water surface to the center of gravity of the torpedo at fire. Applies to above-water launchings only.

TARGET DEPTH. The vertical distance from the center of gravity of the target to the mean water surface. Applies to underwater target only.

TORPEDO DEPTH. The vertical distance from the center of gravity of the torpedo to the mean water surface.

LAUNCHER TORPEDO BEARING. The true bearing from the launcher to the torpedo.

LAUNCHER TORPEDO RANGE. The range from the launcher to the torpedo.

LAUNCHER TARGET RANGE. The range from the launcher to the target.

LAUNCHER TARGET BEARING. The true bearing from the launcher to the target.

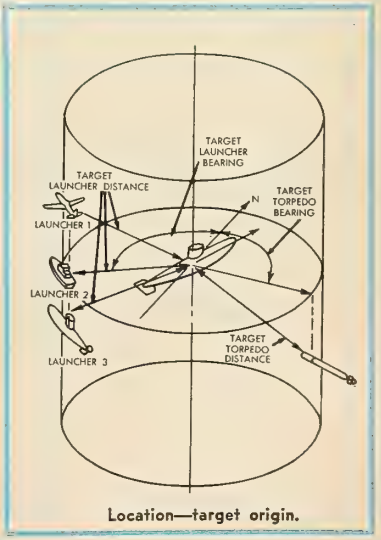
TARGET TORPEDO BEARING. The true bearing from the target to the torpedo.

TARGET TORPEDO DISTANCE. The directed straight line distance between the center of gravity of the target and torpedo, equivalent to torpedo target range.

TARGET LAUNCHER DISTANCE. The directed straight line distance between the center of gravity of the target and launcher, equivalent to launcher target range.

TARGET LAUNCHER BEARING. The true bearing from the target to the launcher.

TORPEDO TARGET BEARING. The true bearing from the torpedo to the target.



DEPTH DIFFERENTIAL. The vertical difference in depth between the target and the torpedo, measured in feet.

Time Variation of Motion

MEAN. The arithmetic average of the instantaneous values of the characteristic over a specified interval.

MEAN AMPLITUDE OF OSCILLATION. The arithmetic average of the maximum displacements of the characteristic with respect to the mean over the same interval specified for the mean.

PEAK AMPLITUDE OF OSCILLATION. The

Location—target origin.

maximum displacement of the characteristic indicated with respect to the mean over the same interval specified for the mean.

FREQUENCY OF OSCILLATION. The average number of cycles per second of a characteristic during the same interval specified for the mean.

PERIOD OF OSCILLATION. The mean time, in seconds, for one complete cycle of the characteristic indicated during the same interval specified for the mean.

Information and Control Terms

STEERING. Steering occurs when direction of the torpedo is controlled in both course and depth.

ENABLING. Enabling occurs when the torpedo becomes capable of making a control response to a detection.

ARMING. Arming occurs when the exploding device of the torpedo becomes capable of detonating the explosive charge.

OPPORTUNITY. An opportunity occurs when the target lies in the field of perception of the torpedo during a search phase. A PERIOD OF OPPORTUNITY is an interval during which the target is continuously in the field of perception of the torpedo. A look is the instant at which there is the maximum probability of target detection.

DETECTION. A detection occurs when the torpedo senses the target, receiving a signal that can be distinguished from the ambient field.

CONTACT. A contact occurs when the torpedo makes a control response as a result of a target detection.

ACQUISITION. An acquisition occurs when a contact endures long enough to establish a trajectory.

LOSS. A loss occurs when a torpedo enters a new search phase after having lost its guidance information during a pursuit phase because of inherent limitations.

ABORTION. An abortion occurs when a torpedo enters a new search phase or discontinues pursuit after having lost its guidance information during a pursuit phase because of torpedo malfunction.

BLANKING (GUIDANCE INFORMATION BLANKING). Blanking is an automatic electronic switch-off designed to occur when the intelligence system of the torpedo becomes so saturated that it can no longer make an effective control interpretation of the information received.

BLANKING RANGE. The distance from the torpedo to the target at which the target field is strong enough to operate the guidance information blanking circuit.

HOLD-IN. The action of a memory device that causes a torpedo to remember and continue upon the same trajectory during gaps in its guidance information.

COURSE HOLD-IN applies to memory guidance in course only.

DEPTH HOLD-IN applies to memory guidance in depth only.

ACOUSTIC RANGE. The range as determined by analysis of the transmitted and reflected signal.

COURSE DYNAMIC RESPONSE TIME. The time delay, in seconds, between receipt of a turn command and the first indication of its dynamic effect.

DEPTH DYNAMIC RESPONSE TIME. The time delay, in seconds, between receipt of an elevation command and the first indication of its dynamic effect.

ECHO AMPLITUDE. The average of the peak amplitudes of the pulses of energy which are reflected from the target and received at the torpedo.

ECHO FREQUENCY. The number of reflected signals received in one second.

ECHO PERIOD. The time between corresponding parts of two successive reflected signals.

ECHO TIME. The duration of a single reflected signal in milliseconds.

FIELD OF PERCEPTION. The nappe within which the directional sensory sensitivity of the torpedo is at least equal to one-half of the maximum.

GATING SENSITIVITY. The maximum amount of signal which may be received by the torpedo's control system which will not cause a gate circuit to function.

PING AMPLITUDE. The average of the peak amplitudes of the pulses of energy which are transmitted from the torpedo.

PING FREQUENCY. The number of pulses of energy transmitted per second.

PING PERIOD. The time between corresponding parts of two successive transmitted pulses.

PING TIME. The duration of a single transmitted pulse in milliseconds.

TRIP DIFFERENTIAL. The number of decibels by which the sum of echo and/or target noise from a target must exceed the sum of ambient and torpedo noise in order to cause a command response.

TRIP LEVEL ANGLE DOWN. The minimum number of degrees below the longitudinal axis of the torpedo from which a signal must come in order to obtain a down-trip of the depth signal relay.

TRIP LEVEL ANGLE UP. The minimum number of degrees above the longitudinal axis of the torpedo from which a signal must come in order to obtain an up-trip of the depth signal relay.

TRIP SENSITIVITY. The maximum amount of sound which may be received by the torpedo's control system which will not cause pick-up or energizing action of the course and/or depth command relays.

HOMING CONTROL LAW. The mathematical expression which most clearly describes the torpedo's track in the pursuit phase.

Environment Terms

AMBIENT FIELD. The absolute potential of the total field of influence, excepting the target and torpedo fields, within the perception capability of the torpedo.

AMBIENT NOISE LEVEL. The acoustic potential of all noise except that generated by the target and torpedo expressed as the equivalent pure tone pressure level in a band width of one cycle per second.

TARGET NOISE LEVEL. The acoustic potential of the target noise expressed as the equivalent pure tone pressure level in a band width of one cycle per second.

TORPEDO NOISE LEVEL. The acoustic potential of the torpedo noise expressed as the equivalent pure tone pressure level in a band width of one cycle per second.

SURFACE TEMPERATURE. The temperature of the sea, at or near the surface, in the area of the torpedo run.

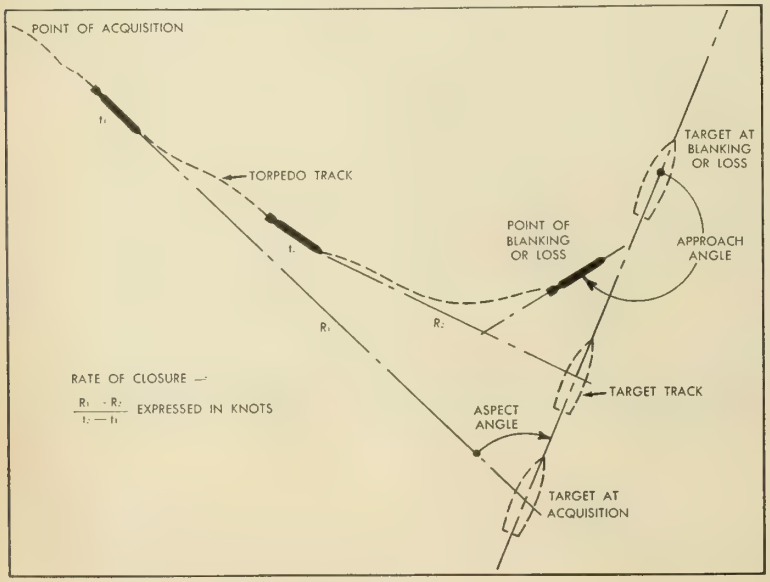
MAXIMUM TEMPERATURE GRADIENT. The maximum rate of change of temperature with vertical distance. A 25-foot band within 100 feet of the depth limits of the run is normally used for measuring the maximum temperature gradient.

DEPTH OF BREAK. The vertical distance below the mean water surface at which an abrupt change in temperature occurs.

SEA STATE. The condition of the surface of the sea by BEAUFORT number.

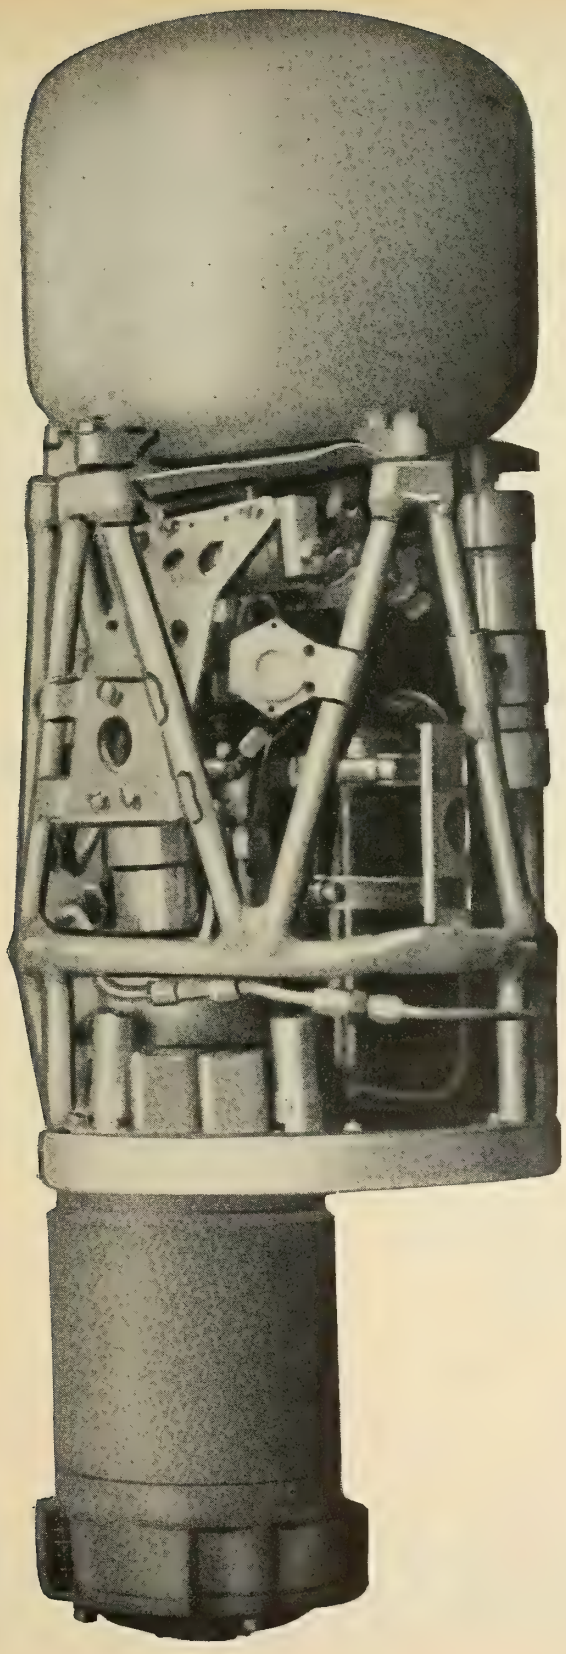
Tactical Performance Terms

SEARCH PATTERN. The predetermined course the torpedo takes during the search phase.



ASPECT ANGLE. The angle measured from the positive direction of the longitudinal axis of the target to a line joining centers of gravity of the target and torpedo.

APPROACH ANGLE. The average angle measured clockwise from the positive direction of the longitudinal axis of the target to the longitudinal axis of the torpedo during the terminal phase, or at the point of hit or point of miss if no terminal phase exists.



RATE OF CLOSURE. The mean rate, in knots, with which the range between the target and the torpedo decreases from point of acquisition to point of blanking, or from point of acquisition to point of hit or point of miss if no point of blanking exists.

MISS. Occurs when the torpedo, in the terminal phase, is no longer directed toward the target.

HIT. Occurs when the torpedo comes in physical contact with the target. ★

Tactical performance terms—approach angle, aspect angle and rate of closure.

Extra Muscle for Missiles

A DEPENDABLE SOURCE OF AUXILIARY POWER

Pioneers in the development of reliable, lightweight, self-contained monofuel auxiliary power systems for guided missiles and piloted high performance aircraft, Kidde now offers its combined engineering talents and precision manufacturing resources to firms interested in advanced applications of auxiliary power systems.

At present, Kidde has available turbine-driven units with horsepower of up to 200. These high speed units are designed to supply accurately regulated power at mean altitudes of 40,000 feet and up. However, they may easily be made environment-free, permitting airframe builders extremely wide latitude in systems design.

As a part of its power system development program, Kidde has gained wide experience with many monopropellants. These include ethylene oxide, hydrazine, hydrogen peroxide and propyl nitrate.

Whatever your present or future auxiliary power requirements, Kidde is ready to develop, test and manufacture equipment which will meet your exact specifications. For full information, write Kidde today.

Scott AIR-PAK

as much a part of
the Weapons System
as the Rocket

Fueling is one of the most important operations in the successful launching of a rocket. Since propellants are poisonous, breathing protection equipment must be worn. The Scott Air-Pak Model 8100-A2 has been designed to meet the exacting requirements of this hazardous operation. It delivers pure, fresh air, instantaneously "on demand" as required by the wearer regardless of the degree of exertion.

Special attention has been given to the metallurgy of the component parts to insure unfailing service in atmospheres of dangerous propellants such as fuming red nitric acid and unsymmetrical dimethyl-hydrazine.

The Scott Air-Pak has been established as standard equipment by Army Chemical Corps and Army Ordnance for launching crew protection.

Write for complete information.

The Scott 8100-A2 Air Pak incorporates the latest advances in chemical resisting materials. Two small compressed air cylinders are used instead of one large cylinder. This reduces bulk and makes the unit easier to wear with protective clothing.

The Scottoramic Mask which is standard equipment completely protects the eyes and face. It provides unlimited vision in all directions and helps the wearer to spot danger zones for maximum safety.

SINCE 1932 Scott FOR SAFETY FOR SERVICE

NEW MISSILE PRODUCTS

LOX TRANSPORTERS

A variety of highway transport units for liquid oxygen and nitrogen handling is being built by Hofman Laboratories in sizes from 500 to 2,500 gal. capacity. All units are built to ASME and ICC specifications and feature use of company's powder-in-vacuum insulated equipment.

Among design features are a quick pressure build-up system, extended stem valves on liquid lines and use of Hofman quick disconnect couplings.

Circle No. 205 on Reader Service Card.

ROTARY TRANSDUCERS

A new line of rotary transducers for sensing angular displacement which utilizes unique construction features to obtain a high degree of instrument stability and accuracy has been announced by Crescent Engineering & Research Co. of El Monte, Calif. Different models exhibit linearity of ± 0.5% or better through 60° of best linear range, and of ± 1% over entire 120° linear range. Special design provides comparative insensitivity to ambient temperature changes.

Miniature precision ball bearings support shaft, otherwise there are no mechanical contacts between rotor assembly and bridge housing to produce friction or electrical noise. Sensitivity is 1 mv/v/o rotation, reproducibility is better than 0.1% and resolution is limited only by external circuitry. Operates in ambient temperatures from —70° to 180°F.

Circle No. 210 on Subscriber Service Card.

"BLINDRILLER"

The problem of locating "blind" holes in non-ferrous structural parts has been solved by the development of a tool named "Blindriller," according to an announcement of the Boeing Airplane Co., Seattle, Washington.

The new tool operates on a magnetic detection principle. A small magnet is inserted in the hidden hole in the structural member and the new device which contains a sensing tube housing a jewel-mounted pointer is placed on the outside skin. Since the pointer is tipped with a magnet having a polarity opposite that of the small magnet marking the hidden hole, the pointer seeks the hidden magnet as the tool is moved slowly around the surface. The hidden hole is accurately located when the pointer is "zeroed."

A slide arrangement supports both the pointer and a drill bushing. Once the hidden hole is located, this slide is shifted to the left as far as it will go and the drill bushing is brought directly over the center.

Although the locator is for use on non-ferrous structures, the close proximity of magnetic materials does not affect its operation. The tool is designed to give 90° angularity within 15 minutes of arc and a maximum .005-inch error in hole.

Circle No. 213 on Subscriber Service Card.

PUSHBUTTON SWITCH

A new "typewriter" pushbutton switch for manual keyboard control of electric equipment is being marketed by Micro Switch, Freeport, Ill., Division of Minneapolis-Honeywell Regulator.

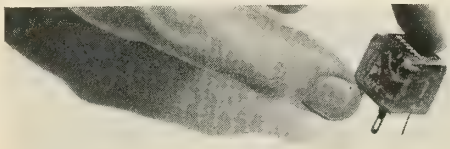
It was developed for rapid-repeat, one-finger operation such as found in the keyboard of electric typewriters, adding machines and similar equipment. Extremely precise, low-force characteristics give the new switch both snap-action and "tap-action."

The new switch (designated the IPB81-T2) employs a single-pole double-throw precision subminiature basic switch for snap-action reliability. Switch and actuator can be operated at frequencies up to 300 times per minute.

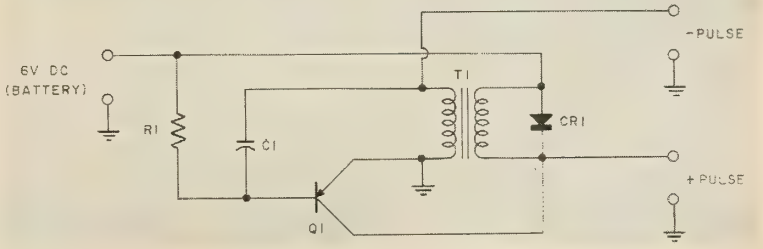
The precision subminiature switch incorporated in the switch is listed by Underwriters Laboratories at 5 amperes 125 or 250 volts ac. The 30-volt dc rating is as follows: inductive, 3 amperes at sea level and 2.5 amperes at 50,000 feet; resistive, 4 amperes at sea level and 50,000 feet. Maximum inrush rating is 15 amperes, 30 volts dc.

Circle No. 250 on Subscriber Service Card.

SPEED REDUCERS



Western Gear Corp. announces the design and manufacture of a new in-line series of speed reducers to be marketed under the trade name "Straitline." Straitline reducers are available in double and triple reduction. Double reduction units



SUBMINIATURE OSCILLATOR

A blocking oscillator contained in an epoxy resin cube measuring ¾" has been produced by Allen B. DuMont Laboratories, Inc. The unit produces a pulse of three miscroseconds duration with a rise time of 0.08 microseconds. Repetition rate is 25 kc.

A six volt mercury cell will power the oscillator for about 1000 hours. Variations of the unit are available to give repetition rates from a fixed 1 kc or variable rates from 400 cps to 24 kc. Operating temperature is from —55°C to 66°C. Either external trigger or free running types may be obtained. Also, plug-in or solder in units can be furnished.

PRECISION GEARS

Precision gears especially suitable for servomechanism use are now offered by Beckman/Helipot Corp. as part of its standard electromechanical breadboard parts line. Spur, spring and clutch gears, and bevel and miter gears are among the types available.

In stock are 48- and 64-pitch spur gears, in tooth multiples of 8 and 10, with 14½° pressure angle, and minimum and

TECHNIQUES and DEVELOPMENTS in oscillographic recording

FROM SANBORN

RECORDING METHOD USED IN SANBORN DIRECT WRITERS, AND A REVIEW OF THEORETICAL AND ACTUAL ERROR FACTORS

Figure 1 shows the basic scheme by which Sanborn oscillographic recording galvanometers produce graphic records of electrical signal values. If the rapid deflection action of the heated ribbon tip stylus is visualized when current flows in the coil, it can be seen that a straight line at right angles to the chart length is recorded on the chart, at the point where the chart is drawn over a knife edge. The trace, therefore, is a true rectangular co-ordinate graph.

Since this is essentially a process of expressing coil (or stylus) deflection *angles* in terms of *distances* on a chart, the trigonometry of the situation (Fig. 2) must be examined to ascertain the accuracy of the method. Initially, and when θ is small, the tangent and the angle are almost equal numerically. The expression $D = R \tan \theta$ can, therefore, be rewritten $D = R\theta$ (approx.). To the extent this latter expression is true, deflection distances (rather than deflection angles) are an accurate measure of signal values. But to determine the extent of error resulting from using this approximation, the following data have been calculated*, using a chart width of 25 mm either side of zero ("D" in Fig. 2) and effective stylus length of 100 mm ("R" in Fig. 2) in the series expansion for the tangent function. Error as a function of deflection then becomes:

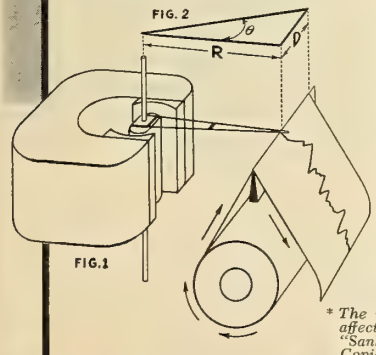

FIG. 1

D mms	Radians	Theoretical Error ϵ	Corrected Error δ	Corrected Error in mms
10	.10	.0033	0	0
15	.15	.0075	.004	.06
20	.20	.0133	.010	.20
25	.25	.0209	.018	.45

When the recording system is calibrated, that calibration is often made on the basis of a one centimeter deflection from the chart center, or by means of a two centimeter deflection starting one centimeter below chart center and finishing one centimeter above chart center. In either case the deflection at one centimeter from chart center is accepted as the standard, and, therefore, is without error. The foregoing table can therefore be corrected by subtracting .0033 from each of the error terms to show the error, δ, to be expected in actual use. The final column in the table shows this error in mms.

Since the active length of the stylus increases as θ increases, deflection D increases more rapidly than θ. All positive error terms in the series expansion bear this out, but the error terms would occur as predicted only if the galvanometer produced deflections exactly proportional to coil currents (that is, ideal spring properties in the torsion rods and uniformity of magnetic field). Pole tips in Sanborn galvanometers are proportioned so that in maximum deflections, galvanometer sensitivity *decreases* slightly, the compensation resulting in *actual* linearity better than that predicted in the table.

* *The mathematics involved here, as well as a discussion of fixed length stylii, design parameters affecting over-all galvanometer performance, etc., are contained in an article by Dr. Arthur Miller "Sanborn Recording Galvanometers," published in the May 1956 Sanborn RIGHT ANGLE. Copies are available on request.*

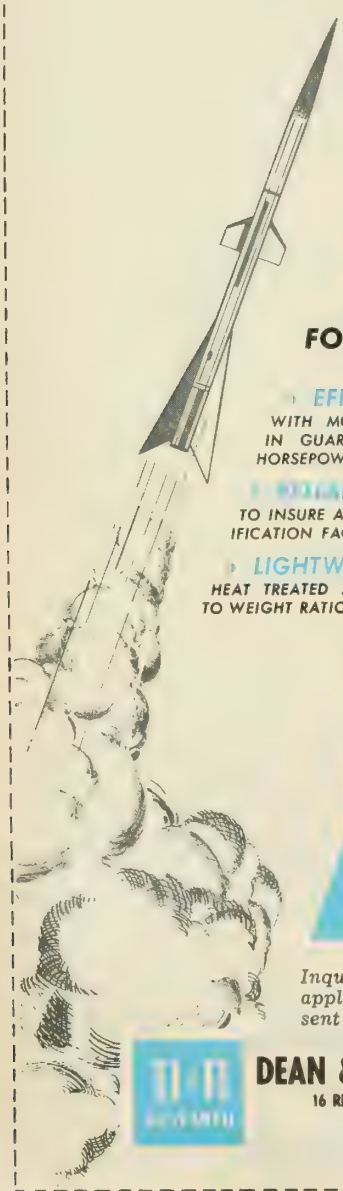
PLATFORM TRUCK

A new 20,000 lb. capacity low-lift platform truck, Model L-15, has been developed by the Elwell-Parker Electric Company, Cleveland.



The truck is available with either electric or gasoline-electric power, has two-wheel drive and all-wheel steer. It is designed for handling odd-shaped and/or extra long loads, particularly where rugged duty is required.

The frame is built of heavy steel plate, formed and electrically welded. Center sill construction is used with all major units attached directly to the heavily reinforced alloy steel bars which form the sills.

The platform is raised by a double-acting hydraulic cylinder.

The truck features a rocking link type platform life with powered lowering accomplished with full inching control through a control valve. A safety link protects the lift mechanism in the event the platform is rammed against an obstruction. A heavy-duty, oversize electric motor drives a tandem hydraulic pump so that a separate oil supply is assured for both the hydraulic lift and the hydraulic steer cylinder.

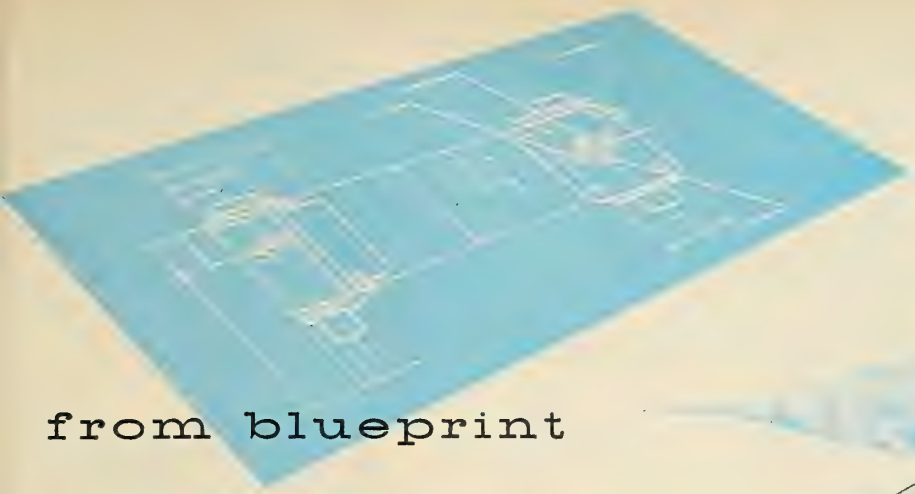
TELEMETERING FILTERS

A new line of subminiature, lightweight telemetering filters for missile applications has been announced by the Pacific Coast Division of Aerovox Corporation. They are 2 cubic inches or less per unit. Telemetering filters for channels 1 through 6 are 1.562" high by .75" by 1.187"; weight is 71 grams (plus/minus 1 gram). Channels 7 through 18 are only 1.375" high by .75" by .75"; weight is 36 grams (plus/minus 1 gram).

Cast in an epoxy-filled resin, all units are hermetically-sealed and will meet applicable MIL Specifications for immersion, shock and environmental tests. All channels will pass 30 G's at 2000 cycles for 2 hours. Temperature range is —55°C. Channel points have standard Johns Hopkins band-pass telemetering call-outs.



Units are made to plug into standard 4-pin Winchester sockets. Standard input impedance is 20K and output impedance is 100K, and can be varied to meet customers' specific requirements.

Circle No. 228 on Subscriber Service Card.

SHUT-OFF VALVES

A new series of high performance shut-off valves for airborne and ground use is now in production at Hydromatics, Inc. These units are designed for applications that require reliable, bubble-tight flow control of extremely low temperature (—320F) and high pressure (3000 psi) media. Typical gases and liquids handled include: oxygen, liquid oxygen, nitrogen, liquid nitrogen, air, liquid air, and helium.

Current is automatically shut off at the end of each valve cycle. In their open or closed position, the valve is positively locked by a Geneva-Lock

from blueprint

to blue skies

From design concept to volume production, Moog's contribution to high performance electro-hydraulics has been unique. Originators of force-balanced nozzle-flapper* and of dry-motor servo valves*, Moog alone has been able to translate these concepts into full volume manufacture. The 40,000 units in the field verify a production record unmatched in the industry. Consult Moog if this kind of design-to-production performance is desired.

ROCKET SWITCHES

Line of precision switches introduced by Micro Switch, division of Minneapolis-Honeywell Regulator Co., are designed to resist effects of highly-corrosive gasses in rocket and missile applications.

Micro series 21AS is essentially an environment-proof, high-capacity switch unit attached to a rugged, cam-type actuator capable of withstanding heavy im-

Afterburner Cooling Assembly Gangs Straight Wall Tubing For High Strength, Light Weight

A minimum weight plus complex fabricating problems were critical factors in the development of this afterburner cooling blast tube assembly.

The space envelope was shallow and wide and over six feet long. The assembly was required to be tested at 28 psig with collapsing pressure of −2.5 psig and at a temperature of 250° F.

Flexonics answered the need by

End view of afterburner cooling assembly. Note rectangular shape of ends.

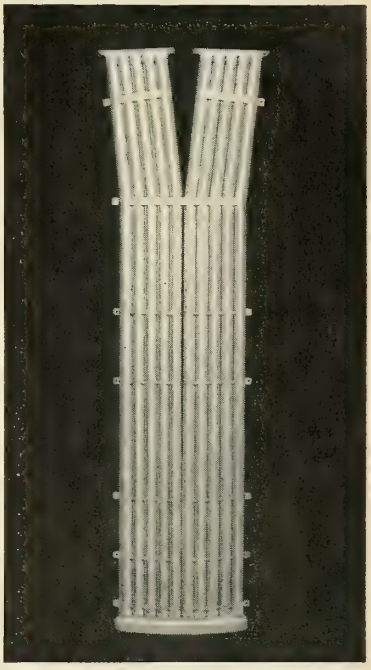
forming standard High Strength welded tubing into a gang. Ends of the tubes were formed to a rectangular shape to adapt them to the required end fittings. The tubes are held together with welded bands as the illustration of the unit shows. Tabs are provided for mounting in the airframe.

Tubing used in the assembly is 1.625″ O.D. by .011″ wall thickness. Type 321 High Strength stainless steel is used, with ultimate of 100,000 psi.

Facilities are the Key Factor

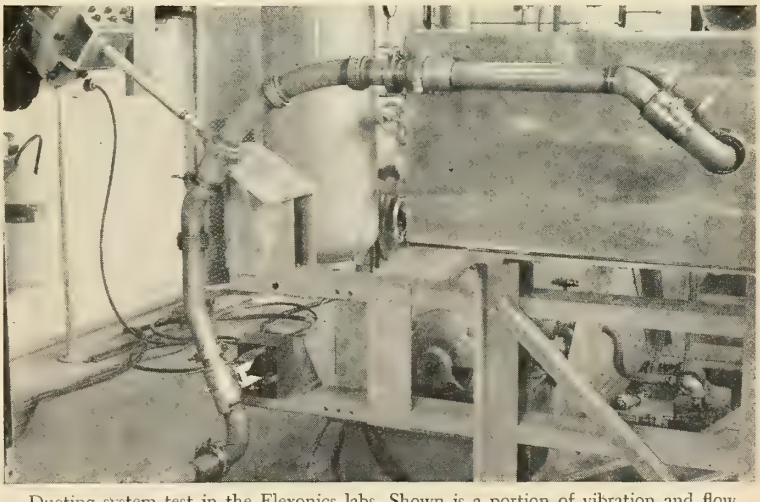
In the engineering, fabrication and proving of assemblies such as this, facilities are all important. As the pioneer and leading manufacturer of light weight corrosion resistant flexible assemblies and ducting, Flexonics Corporation has facilities second to none.

The engineering skill of Flexonics Corporation is proved by the scores of developments already made ranging from single flex connectors to entire aircraft ducting systems.



The manufacturing know-how of Flexonics Corporation is proved by the daily trouble free production of intricate assemblies and by such developments as the re-deposition process of forming ducting components.

The ability to prove assemblies before their installation in aircraft and engines is assured by the extensive Flexonics laboratories capable of the most advanced testing procedures.



Engineering Assistance

Whenever you have a problem involving aircraft plumbing, take advantage of the know-how and facilities of Flexonics Corporation. For specific recommendations send an outline of your requirements.

For help right at your desk, write for information on how qualified persons can secure copies of the new Flexonics Engineering Manual.

Complete afterburner cooling assembly. Note use of straps to gang the tubing.

Ducting system test in the Flexonics labs. Shown is a portion of vibration and flow under pressure tests of assemblies in a bleed air system for a current fighter aircraft.

NOW, FROM FLEXONICS A COMPLETE LINE OF FLEXIBLE CONNECTORS AND DUCTING

With the acquisition of FLEX-O-TUBE Division, Flexonics Corporation is now able to offer a complete line of rubber, synthetic and Teflon hose assemblies and crimped-on and re-usable fittings. Write for full information.

TACHOMETER CALIBRATOR

A new type of test instrument is announced by Servo-Tek Products Co., Model ST-901 Tachometer Calibrator. It is basically an electronic decade type counter combined with the maker's precision electronic adjustable-speed drive. The tachometer under test is driven at a speed (usually from 0 to 5000 rpm) that is infinitely adjustable by means of a 10-turn potentiometer. For rapid production testing, a push-button switch will select any one of five pre-determined test speeds.

The driving speed is continuously displayed with an accuracy of 1 rpm, plus line frequency error. Provisions are made for use of the counter for other purposes such as checking inverter frequency, telemetering switch counts, etc. Counting speeds up to 50,000 per second are possible. An electronic pick up is supplied as a standard accessory to permit checking the rotational or lineal speed of various motors, gear trains, etc.

INDUSTRY SPOTLIGHT

By Joseph S. Murphy

Guided Missile Firms Again High on Defense Contract Lists

Guided missile airframe, guidance and powerplant producers ranked high on the list last month as Defense Department tabulated its top contract award winners for the 18-months from January 1, 1955 through June 30, 1956.

In all, some 19 of the first 20 firms are playing a prominent role in one or more missile or rocket programs. The only exception, Ford Motor Co., can hardly be considered an outsider in the missile business with the establishment last year of its new subsidiary, Aeronutronics Systems, Inc.

Heading the Defense list was North American Aviation, Inc. (*Navaho,* X-10 and liquid rocket engine producer) with $1,340.6 millions in contracts. General Dynamics (Convair) ranked second at $1,339.7 and is prime contractor for the *Terrier* and *Atlas* plus other missile projects.

Rounding out the billion-dollar group are United Aircraft (J57 engine for *Snark*) at $1,273.6 million; General Electric (*Hermes, Atlas* nose cone and guidance, J79 engine for *Regulus II*) at $1,051.2 million; and Boeing Airplane Co. *Bomarc* at $1,016.1 million.

Here's how missile firms shaped up in the million-dollar class of award winners: American Telephone & Telegraph Co. (Western Electric in *Nike* and Bell Laboratories in ICBM guidance)—$747.1 million.

Lockheed Aircraft Corp. (X-7, X-17 and *Polaris*)—$657.5 million.

Douglas Aircraft Co. (*Nike, Honest John, Thor* and *Ding Dong*)—$592.8 million.

McDonnell Aircraft Corp. (*Talos* and *Green Quail*)—$522.4 million.

Hughes Aircraft Co. (*Falcon*)—$477.1 million.

Curtiss-Wright Corp.—(Aerophysics HTV and *Dart,* ramjet for *Navaho*)—$464.2 million.

The Martin Co. (*Matador, Bullpup, Lacrosse* and *Titan*)—$406.0 million.

General Motors—(Allison J33 for *Regulus* and *Matador,* AC Spark Plug guidance for ICBM)—$326.3 million.

Bendix Aviation Corp. (*Talos* and *Loki*)—$295.4 million.

International Business Machines (computers for various projects)—$275.3 million.

Chance Vought Aircraft, Inc. (*Regulus* I and II)—$221.5 million.

Radio Corp. of America (*Talos* systems)—$221.3 million.

Sperry Rand Corp. (*Sparrow*)—$209.2 million.

Republic Aviation Corp.—(*Terrapin* rocket, ICBM nose cone subcontractor)—$200.8 million.

Missile representation throughout Defense's top 100 contractors includes some 13 other firms involved in major projects. On this list are Raytheon Mfg. Co. (*Sparrow* and *Hawk*); General Tire & Rubber Co. (Aerojet-General rockets); Goodyear Tire & Rubber Co. (Goodyear Aircraft's *Matador B* guidance and ground support); Northrop Aircraft, Inc. (*Snark*); Philco Corp. (*Sidewinder*); and Avco Mfg. Corp. (*Titan* ICBM nose cone).

Remaining seven included Westinghouse Electric Corp. (*Bomarc* guidance); Fairchild Engine and Airplane Corp. (*Goose* and *Petrel*); Bell Aircraft Corp. (*Rascal*); Firestone Tire & Rubber Co. (*Corporal*); Minneapolis-Honeywell Regulator Co. (ICBM guidance); Gilfillan Bros. (*Corporal*) (ground guidance system); American Bosch Arma Corp. (ICBM guidance); and Chrysler Corp. (*Redstone*).

General Electric Sets First Quarter Record In Sales and Earnings, President Reports

General Electric Co. set new first-quarter records in both sales and earnings during the first three months of 1957, President Ralph J. Cordiner has announced. Sales billed, he said, amounted to $1,048,850,000, an increase of 11 per cent over the previous first-quarter record of $946,458,000 set in 1956, and a 26 per cent increase over the first quarter of 1955.

Cordiner reported that General Electric plans to invest approximately $185 million in new plant and equipment during 1957. This, on top of expenditures of $205 million last year, indicates that the Co. will invest "substantially more" than the $500 million originally scheduled for expansion and modernization in its three-year program for 1956-58, he said.

Cordiner reported net earnings for the quarter of $64,006,000, up 16 per cent over comparable 1956 earnings of $54,962,000, and 22 per cent higher than first-quarter 1955 earnings. The earnings were equivalent to 73 cents per share of common stock and 6.1 cents per dollar of sales as compared with 63 cents per share and 5.8 cents per sales dollar for first quarter 1956, and 6.3 cents per sales dollar in the first quarter of 1955.

Also set new records in employee earnings and in payments to suppliers during the quarter, Cordiner said. Employee pay and benefits applicable to sales, during the quarter reached a record $399,141,000. Purchases of materials, supplies and services from the Company's approximately 42,000 suppliers amounted to approximately $485 million. Also made provision during the quarter for payment of $100,143,000 in direct federal, state and local taxes and renegotiation in addition to indirect taxes included in prices paid to suppliers.

Thiokol Builds *Nike* Sustainer

Nike-Hercules surface-to-air missile is to incorporate a Thiokol solid-propellant sustainer unit.

The new missile is scheduled to be in the hands of operational *Nike* batteries in the very near future. Its higher velocity will permit swifter interception of the most advanced types of aircraft, and its increased lethality will make *Nike-Hercules* one of the most effective weapons in American defense areas.

The sustainer unit is one of the many solid-propellant powerplants re-

cently developed by Thiokol Chemical Corporation.

The *LaCrosse, Falcon, Matador B,* and RV-A-10 all incorporate this type of powerplant. According to a recent announcement by the U.S. Army and the Western Electric Company, prime contractor for the *Nike System,* this new version of the *Nike* missile is now undergoing final tests.

Although longer, heavier, and more than double the diameter of *Nike-Ajax,* the *Hercules* model will have extreme maneuverability at altitudes far in excess of those capable of being reached by *Ajax.*

The *Nike-Hercules* is to be produced initially at the Douglas Aircraft Santa Monica plant and followed with additional production at the Douglas-operated Charlotte Ordnance Missile Plant at Charlotte, North Carolina. Nuclear capability will be incorporated into the *Nike-Hercules* surface-to-air guided missile system.

Reaction Motors Builds X-15 Engine

Air Force has confirmed that Reaction Motors, Inc., is developing an "advanced-design liquid propellant rocket engine" for the North American Aviation X-15 research airplane.

Missile Obligations Exceed $10 Billion In Eight Years, Aircraft Assn. Reports

Guided missile obligations for the eight years starting in June 1950 and ending June 1958 will total $10,173,930,000 or 8.2% of the $124,348,916,000 total Defense and procurement monies for the period, according to Aircraft Industries Assn.

However, the last half of this period accounts for better than 80% of the missile dollar obligations — $8,359,406,000 for fiscal years 1944 through 1958.

By individual service, AIA shows this summary of obligations:

Army—For eight-year period obligated $2,784,045,000 of which about $2.1 billion was obligated during fiscal 1955-58.

Navy — obligated $1,808,082,000 for eight years and, of this, $1,254,165,00 was for fiscal 1955-58.

Air Force—Eight-year obligations for missiles amounted to $5,581,803,000 of which $4,985,653,000 was obligated in the fiscal 1955-58 period.

Here's how missile obligations compared with total procurement and production monies for fiscal 1950 through 1958:

	Major Procurement & Production Funds ($000's)	Missile Obligations ($000's)
Fiscal 1951		
Army	$6,953,064	$34,600
Navy	6,092,476	119,090
Air Force ..	8,789,349	121,292
Total	21,844,889	274,982
Fiscal 1952		
Army	8,909,576	190,687
Navy	7,813,797	141,332
Air Force ..	11,979,814	68,417
Total	28,703,186	400,436
Fiscal 1953		
Army	3,489,999	212,915
Navy	5,009,174	154,124
Air Force ..	10,235,253	228,594
Total	18,734,426	504,633
Fiscal 1954		
Army	515,237	317,255
Navy	1,878,358	139,371
Air Force ..	1,928,592	177,847
Total	4,322,187	634,473
Fiscal 1955		
Army	2,185,568	349,554
Navy	1,404,537	116,589
Air Force ..	5,981,853	547,934
Total	9,648,793	1,014,077
Fiscal 1956		
Army	1,150,118	354,034
Navy	4,199,653	232,576
Air Force ..	7,141,587	859,719
Total	12,891,435	1,446,329
Fiscal 1957 (Estimated)		
Army	1,601,000	743,000
Navy	4,093,000	440,000
Air Force ..	8,425,000	1,888,000
Total	14,119,000	3,071,000
Fiscal 1958		
Army	1,359,000	673,000
Navy	4,245,000	465,000
Air Force ..	8,479,000	1,690,000
Total	$14,085,000	$2,828,000

SAM Details Revealed In Released Pix

English Electric has been permitted to release three photographs of its Napier-rocket powered SAM ordered for UK defense. The photographs have been released before, but not identified with English Electric. The missile has cruciform wings of 1.0 aspect ratio and cruciform tail guidance blades. Dipole antenna are featured both fore and aft. Take-off boosters are in four pairs on wrap-around explosive cord or bolt mount, each pair with a guidance fin. This type of booster is used on Napier's RJTV experimental ramjet.

LIQUID OXYGEN AND NITROGEN TRANSPORT UNITS

Hofman 3000 Gallon Trailer

Built to A.S.M.E. and I.C.C. specifications in sizes from 500 to 3500 gallons. Efficient performance is shown in this Hofman powder in vacuum insulated equipment. Standard features include: bottom fill and discharge line, top fill line, liquid level gauge, vacuum valve and filter, thermocouple vacuum gauge, pressure gauge, A.S.M.E. code stamped inner vessels, quick pressure build-up system, extended stem valves on liquid lines, ending with Hofman quick couplings.

Marquardt is Growing...

offering new opportunities to professional engineers

ROBERT L. EARLE, EXECUTIVE VICE PRESIDENT, *is second in command of the Marquardt engineering-production team. He is shown at Marquardt's new production plant now under construction at Ogden, Utah.*

Freedom to pioneer — freedom to grow . . . these are the challenges and new engineering opportunities at Marquardt Aircraft.

Through these freedoms, Marquardt stands established as the leader in ramjets, "powerplant of the future."

Through these freedoms, Marquardt leads the way into advanced engineering projects.

These freedoms — pioneering and growth — are as individual as each professional engineer, as collective as the entire Marquardt team. Through them, Marquardt now offers new and unlimited opportunity for professional engineers in two of the West's most stimulating areas. At Ogden, Utah, in the heart of the Wasatch Mountain vacation area, Marquardt is now constructing a multi-million dollar production plant to produce supersonic powerplants for the Boeing Bomarc interceptor missile. And in Southern California's San Fernando Valley, Marquardt professional engineers are involved in a major expansion program for design, development, and test of new ramjet engines and turbojet and ramjet controls.

If you are a professional engineer interested in the freedom to pioneer — the freedom to grow — for yourself and your company, we invite you to investigate the opportunities at Marquardt Aircraft, today. Please contact Jim Dale, Professional Personnel, 16551 Saticoy Street, Van Nuys, Calif.

Industry Highlights

By Fred S. Hunter

At the time of this writing—in April—the initial test firing of the Convair/Ramo-Wooldridge/Western Development Division *Atlas* prototype had not taken place at the Air Force missile test center in Florida, but perhaps by the time you read this the big event may have occurred. So let's call this *Atlas* month and talk about the big ICBM.

Karel J. (Charlie) Bossart, now technical director of Convair's Astronautics Division, named it the *Atlas*. It's a fitting name. Holds up the world. But there was an additional consideration at the time Bossart picked Atlas out of the dictionary. Convair's controlling stockholder then was Floyd Odlum's Atlas Corp.

Model number for the *Atlas* is SM-65, weapons system designation is WS-107A and Convair's house number for it is Model 7. Latter shows that Convair actually started on the ballistic missile project before its delta wing F-102 all-weather interceptor came along. The F-102 is the Model 8 on the Convair books.

Convair's Astronautics division currently is conducting its operations in the company's Plant 1 at San Diego—that's where the commercial Model 440 Metropolitans are assembled—but it expects to be fully established in its new home on Kearny Mesa in January next year. This $40-million domicile for Convair's prize bird includes a manufacturing facility, due for completion in November, an engineering building and two six-story office buildings.

Astronautics now has about 6,000 employes, and it will peak at about 7,000 in the new facility. It will have a couple of thousand more, however, at outside test locations. The division payroll will exceed $50 million a year.

Only recently did General Dynamics Corp. give Convair's Astronautics division full division status, like that of the company's Pomona Navy missile enterprise, but Convair has been working on an intercontinental ballistics missile program ever since April 22, 1946. That's when the Air Force gave it a study contract of very modest proportions—something less than $2 million, as we recall—for the MX-774. "Charlie" Bossert was the project engineer. Now, if you think the projected *Atlas* prototype test in Florida represents Convair's first test firing of a ballistic-type missile. You're wrong. There were three test vehicle firings of the MX-774 at White Sands in 1948. Reaction Motors made the four rocket motors powering the test vehicle.

The MX-774 was ordered terminated in the Louis Johnson economy program of 1947, but Convair was permitted to continue the project as long as the money originally budgeted held out. That's how it got in the subsequent test firings. But Convair was so thoroughly convinced of the nation's need for the "ultimate weapon" that even when the last dollar was spent it kept an engineering group on the project with its own funds. This was the situation when the Air Force came through in January, 1951, with a new contract for the MX-1593. This was the *Atlas*.

Atlas has grown considerably over the years. The MX-774, as we recollect, was 34 feet long. When Convair was ready to ship the *Atlas* prototype to Florida last December it had to truck it—a 10-day journey. Strangely enough, it attracted practically no curiosity en route. The people have become accustomed to seeing almost anything on the highway so those who passed the big canvas-covered shape on the road apparently didn't give it a second thought. One reason we were somewhat surprised when the Air Force shot down the Douglas C-132 for lack of funds the other day, was we had assumed all along that a primary function of the big turboprop would be to airlift such large-scale items as the *Atlas* and the Martin *Titan*. We understand the C-133 will hold the *Atlas*, but it's a tight fit—or so we hear.

Crucible Sales Top $70 Million

Crucible Steel Co. of America's sales of $70,598,795 in the first quarter of 1957 were the largest for any first quarter, but moderately below the level of the previous quarter, President Joel Hunter announced.

Net earnings for the first quarter amounted to $0.93 per share as compared with $1.01 per share in the 1956 quarter, based on the 3,638,562 common shares currently outstanding.

Directors elected for a three-year term of office were Joel Hunter, President; Walter H. Wiewel, Senior Vice President; Lawrence N. Murray, President, Mellon National Bank and Trust Co., and William H. Rea, President, Oliver Tyrone Corporation.

Honeywell Tests Guidance System

Minneapolis-Honeywell Regulator Co. has flight tested a new "pure" inertial navigating system for automatic guidance of manned or unmanned aircraft, it has been announced.

Several tests have been made from Honeywell's flight operations center at the Minneapolis-St. Paul Municipal Airport. The airplane which transported the highly-intricate aerial "brain" has ranged over several-hundred mile courses in Minnesota and Wisconsin.

Work on the system (designated ISIP, short for Inertial System, Indicating Position) has been going on for several years in the Aeronautical Division's research facility under a Navy development contract. The Air Force, too, has shown an interest in Honeywell's ISIP self-navigator.

Grumman Launches Bid For Subcontracting

Grumman Aircraft Engineering Corp., one of the few major aircraft firms not playing a major role in the current missile program, has launched a permanent subcontracting program that presumably will include missile work.

Company officials report that work complete and underway totals more than $7 million, with one order from General Electric worth in excess of $500,000 already delivered. Grumman also holds subcontracts from Sperry Gyroscope Co., Fairchild Aircraft Division, Chance Vought Aircraft and McDonnell Aircraft Corp.

All are active in one or more missile programs including Sperry (*Sparrow*), Fairchild (*Goose*), Chance Vought (*Regulus*) and McDonnell (*Tales* and *Green Quail*).

The Martin Co. Drops the "Glenn"

The Glenn L. Martin Co.'s stockholders have voted at their annual meeting to shorten the firm's name to "The Martin Company." This was done, the company said, "in keeping with industry's growing recognition of the greater impact of foreshortening company names."

Other formal business at the meeting included the re-election, as Directors, of George M. Bunker, Duncan M. Spencer and John L. Sullivan. Other Directors of the Company include Howard Bruce, William A. Burns, Jr., John E. Parker, Everett H. Pixley, Alexander B. Royce and Frank F. Russell.

At the meeting, it was announced that sales for the first quarter of 1957 were $98,748,234, an increase of 93 per cent over sales of $51,132,853 for the same period of 1956. Sales volume is approximately in line with the rate forecast for the full year.

The increase reflects both the higher current rate of activity as well as the fact that last year's first quarter

MOLYKOTE® LUBRICANTS...
ALREADY SOLVING PROBLEMS IN THE AGE OF ASTRONAUTICS

Born in the "fringe area" of industrial lubrication, MOLYKOTE Lubricants have grown under the pressure of the toughest problems industry has to offer. Extreme pressures and temperatures: unusual environments, high starting friction, resistance to centrifugal force, obstinate fretting . . . MOLYKOTE has solved many. Truly, MOLYKOTE has been called "Industry's Most Versatile Lubricant".

To the Age of Astronautics MOLYKOTE brings ● THERMAL STABILITY, retaining its lubricity from -300°F to 700°F in air. 2000°F in vacuum ● CHEMICAL STABILITY, resists all but a few strong acids ● A NATURAL AFFINITY for adherence to metal, rubber, plastics, etc. ● A FAVORABLE LUBRICANT structure. Low friction sliding surfaces are an integral part of the molecule ● RESISTS PRESSURES beyond the yield point of any metal.

Send today for complete data on the entire line of MOLYKOTE Lubricants.

WHAT'S THE WEATHER 30 MILES UP?
CDC WASP REPORTS BACK IN 60 SECONDS

THE WASP IS A SINGLE-STAGE SOLID PROPELLANT ROCKET
LENGTH: 103"; DIAMETER: 3"; WEIGHT: 22.5 LB.

That's a radar reflective chute just ejected from a CDC rocket launched only 60 seconds ago. Far below, a Navy research team is getting instantaneous answers to important weather questions—filling gaps in man's knowledge about wind profiles between *50,000* and *200,000* feet.

This missile system is currently performing useful research tasks for NOL, ONR, Redstone and the Signal Corps. It also is being employed in the IGY program. Redesigned from the LOKI missile developed by Cal Tech Jet Propulsion Lab for Army Ordnance, it is an outstanding example of CDC creativity. CDC offers full services in design, development, instrumentation, fabrication, field testing and data evaluation. How can CDC serve *you?*

Write for detailed information on CDC capabilities in rocket and electronic systems for scientific and military applications.

SCIENTISTS AND CREATIVE ENGINEERS . . . INVESTIGATE THIS FIELD WITH A FUTURE. CHALLENGING WORKING ENVIRONMENT IN SOUTHERN CALIFORNIA.

DESIGNERS AND BUILDERS OF THE ASP — THE WORLD'S FASTEST SINGLE-STAGE SOLID PROPELLANT ROCKET

sales were somewhat less than normal.

Net income for the first quarter of 1957 was $2,009,535, equivalent to 69 cents per share compared to $1,586,725 and 56 cents per share last year. Net income, although ahead of last year's first quarter, is lower than expected for the rest of the year.

Bell Earns Slightly Less Sales Hit Peacetime High

Bell Aircraft Corp., manufacturer of the *Rascal* long-range air-to-surface missile, reports 1956 earnings of $5,761,103, down slightly from 1955. Sales of $216,033,290 plus other income of $1,040,937 marked a new peacetime high for the company.

Leston Faneuf, Bell president, attributed the decline in earnings to increased wage rates and material costs, unusually high starting load costs on products being built under fixed-price contracts, plus continually growing development and engineering expense.

In its annual report, Bell reported its engineers have designed and developed rocket engines for five guided missiles only one of which is now operational. It also reported completion of laboratory evaluation of more than 50 rocket propellants over a three-year period and some 15,000 rocket thrust chamber runs in more than 50 test cells it operates.

Bell now estimates it consumes about 350,000 pounds of oxidizer and 100,000 pounds of fuel each month in such testing.

Army Lets Contracts For New Lox Plants

Army Corps of Engineers has awarded a contract to Air Products, Inc. of Allentown, Pa. for construction of two liquid oxygen generator plants.

Each unit will be capable of producing a 50-ton daily supply of high-purity Lox for missile use, yet will be designed for dismantling and shipment via cargo aircraft. According to API officials, the largest air-transportable oxygen plant now in operations is rated to produce only 10 tons per day.

GE Sets Up Group For Missile Arming

Missile and Ordnance Dept. of General Electric Co. at Philadelphia has been expanded to include a special organization for R&D in nuclear arming and fuzing devices for missiles.

Group is designated the Nuclear Ordnance Projects Operation and will be responsible for all arming and fuzing development work including electro-

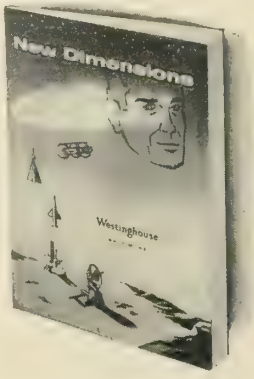
Exciting News About The Revolutionary "PARABALLOON"

The Original Paraballoon was mounted on a metal support. Only the antenna and balloon protector were air supported.

Westinghouse - Baltimore Engineers Have Adapted This Radical Antenna For Use In Scatter Communications



Just a few short months after the development of the Paraballoon by Westinghouse-Baltimore engineers, these same engineers have developed an entirely new application for it . . . which promises to revolutionize "over-the-horizon" scatter communications. The new Paraballoon application is just one more example of the pioneering leadership synonymous with the name Westinghouse-Baltimore.

Now . . . The Paraballoon is completely air supported — even lighter and more easily erected. Air supported structures as large as 65 ft. in diameter and over 100 ft. high are under study.

From Westinghouse-Baltimore comes an exciting new book every engineer's family should read.

"New Dimensions"—a book of engineering career opportunities—tells you what you and your family want to know about job opportunities, growth possibilities, attractive benefits and a rich, full life in a progressive community.

mechanical devices used to arm and detonate missile warheads.

G. F. Metcalf, department general manager, said the group has contracts requiring production of recently developed system designs for current Army Ordnance missile warheads, as well as R&D into new and improved systems for future operational missiles.

Farnsworth Contracts Over $12 Million

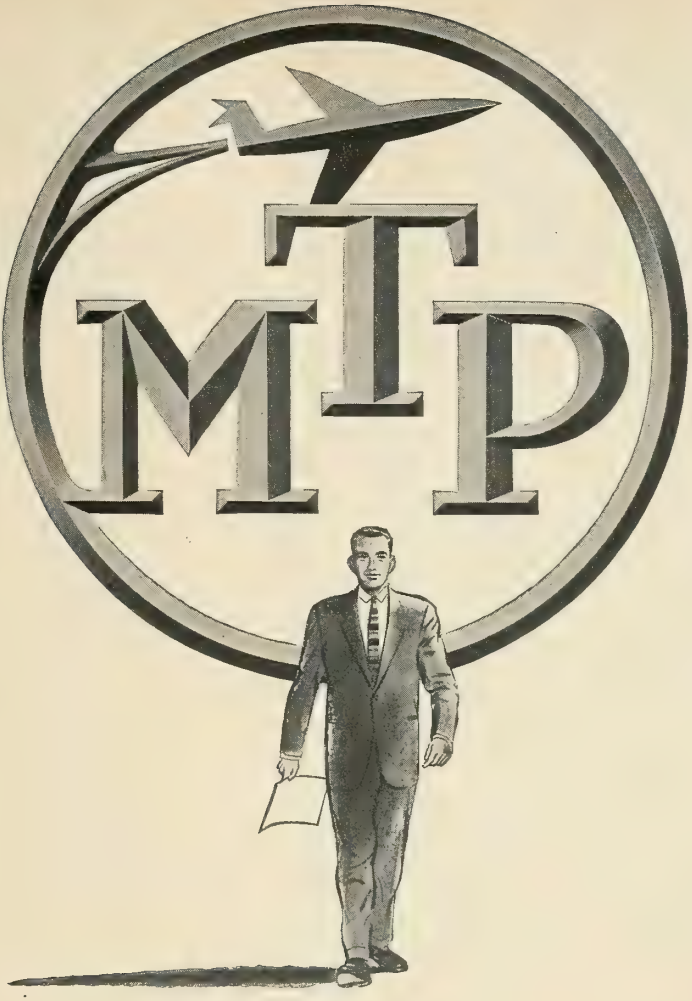
I. G. Haggerty, President of Farnsworth Electronics Co., Fort Wayne, Ind., a division of IT&T, announced that the company had received additional orders amounting to more than $12-million from the Boeing Airplane Co. in Seattle, Wash.

The contract calls for the provision of additional ground support and operational test equipment for the Bomarc Missile, currently being produced by Boeing for the USAF. According to Mr. Haggerty, Farnsworth, long active in the production of automatic and specialized test equipment for missiles and for other complex electronic and electro-mechanical devices, did the original prototype development of the equipment just ordered.

Small Business Contracts Hit $1.6 Billion

Subcontract awards by 163 large firms to small business almost matched the dollar volume received directly from the Defense Department in prime contracts during the last half of 1956, Defense officials report.

Major companies participating in Pentagon's Small Business Subcontracting Program reported $1.430 billion awarded small business during the period compared to $1.616 billion awarded by Defense as prime contracts.



According to Pentagon estimates, the $1.430 billion represents 20.9% of the total military prime and subcontract receipts of the 163 firms reporting receipts and payments under Army, Navy and Air Force contracts.

Brush Sets Up Branch in L.A.

Brush Electronics Co., Cleveland, Ohio, manufacturers of industrial and research instruments, has established a factory branch office in Los Angeles.

MISSILE PROJECT ENGINEER
Coordinate project analysis, planning and controls including determination of project requirements and commitments in missile field.

ELECTRONIC SYSTEMS ENGINEER (Field Service)
Liaison with associate contractors and government agencies on inertial guidance system project. Must be thoroughly familiar with matters relating to digital and analog computers, power supplies, environmental conditions, housing and test facilities and test equipment.

FIELD EVALUATION ENGINEER
Perform overall planning functions for field evaluation of missile guidance systems. Direct activities in scheduling the field operations. Liaison with field test site agencies and formulating overall operating procedures at test site on missile project.

MECHANICAL DESIGN ENGINEER
Perform mechanical design of airborne instrumentation and transducers required for field evaluation of missile guidance systems. Responsible for packaging and mounting equipments.

FUNCTIONAL ENGINEERS—MISSILE SYSTEMS
Develop inertial guidance systems including gyro, accelerometers, integrators, servo systems and computers. Analyze functional problems arising during development and evaluation of said system.

OPERATIONAL EVALUATION ENGINEER
Perform engineering studies and analysis of techniques for evaluating performance of missile guidance systems and its components including gyros, accelerometers, digital computers.

PLATFORM ENGINEER
Conduct investigation of a theoretical nature relating to gyros or inertial platforms including design of closed loop control equipment pertaining to the above.

GYRO DEVELOPMENT ENGINEER
Develop precision gyro systems including mechanical problems such as lubrication, temperature controls, hydrostatics and vibration and electronic work on accelerometers, amplifiers, torquing circuits and electrical pickups.

OPERATIONAL ANALYSIS ENGINEER
Development work on evaluation of inertial guidance systems including in-plant and flight analysis of gyro systems. Development of measuring devices for precise determination of in-flight velocity, acceleration, altitude and position information.

RELIABILITY ENGINEER
Develop methods for evaluation of accuracy, reliability and operational suitability of missile guidance systems.

SYSTEMS EVALUATION (MISSILE GUIDANCE)
Perform functional engineering studies and design of inertial guidance systems, determine system and component requirements and performance, conduct system and component dynamic studies and simulation, perform error analysis.

PROJECT ENGINEER—
PRODUCTION TEST EQUIPMENT
Administer and technically direct the program of design, development and manufacture of test equipment for production use in the manufacture, inspection, test and reliability control of highly complex electronic, electro-mechanical and gyroscopic equipment required for missile application.

GROUND EQUIPMENT ENGINEER
High degree of technical and administrative responsibility on complex projects involving the design and development of production test and field test equipment for gyroscopic systems and digital computers.

PROJECT ENGINEER—AIRBORNE EQUIPMENT
Guide and assist engineers in technical problems in field of electrical and electronic design, servo systems, missile guidance systems. Responsible for major product improvement program and test programs. Provide technical liaison with quality control. Heavy servo background desired.

ENVIRONMENTAL ENGINEER
To plan, conduct and report upon development studies of finishes, materials and processes, which will be incorporated into the design of electromechanical and electronic components and systems.

OPERATIONAL ANALYSIS ENGINEER
To plan, conduct and report upon environmental tests of electromechanical and electronic systems. Must be capable of redesigning components or systems to correct any deficiencies encountered during the evaluation program in the computer, servo systems and missile field.

QUALITY CONTROL ENGINEER
Require experience in gyroscopic trouble shooting. Design knowledge of stable elements and some background regarding reliability and failure association for complex guidance systems to be used in missile field. Must have complete knowledge of statistical methods.

GROUND EQUIPMENT ENGINEER
Plans and performs engineering studies, basic electrical and mechanical design, development and evaluation of production test and field test equipment where specific objectives and general requirements are known. Must be familiar with electromechanical instrumentation.

Clip the job (or jobs) you're interested in and mail, with your confidential resume. No reference contact without your permission. You'll receive a prompt reply, and your copy of "Your Engineering Career with Arma," full of detailed information about this company.

sonnel will be added as required, said C. B. Hoffman, sales vice president.

Martin Awards Contract For New Orlando Plant

The Martin Co. has let contracts totaling $6,031,950 with Thompson & Street Co. of Charlotte, S. C. for construction of a new plant at Orlando, Fla., location of its present *Lacrosse* missile production.

The new facility, situated on a 6,777-acre site purchased by Martin last September, is slated for use in R&D and production of newer weapons in the missile, electronics, nucleonics and small weapons fields.

Martin is handling *Lacrosse* manufacture in interim facilities near Orlando and presumably will shift this activity to the new plant when completed later this year.

Plan for the new structure calls for about 488,000 sq. ft. in four buildings. Main building measuring 640 by 500 ft. will provide 290,000 sq. ft. of manufacturing, assembly, shop and storage space.

Southwestern Gets Convair Contract

Southwestern Industries Inc., Los Angeles, has received a contract from Convair, a division of General Dynamics Corp., for design and manufacture of pressure switches, Southwestern President F. P. Jenks has announced. The switches will be used in classified missile applications by Convair-Astronautics in San Diego, Jenks added. Dollar value of the contract was not disclosed.

Texas Nuclear Installs Atom Smasher

Texas Nuclear has completed installation of its "atom smasher" at Austin, Tex.

The company initially is using its 2-million-volt positive-ion accelerator purchased from High Voltage Engineering Corporation, Burlington, Mass., in programs dealing with elastic and inelastic scattering of neutrons.

Missiles Support Functions to go to San Bernardino

Transfer of the Ballistic Missiles logistical support functions, now at Maywood Air Force Depot to Norton Air Force Base at San Bernardino, Calif. will take place in the near future, it has been announced.

The Ballistic Missile Management

An Announcement

OF FIRST IMPORTANCE TO EXPERIENCED ROCKET ENGINEERS AND SCIENTISTS

- *Reaction Motors initiating big new Research and Development Program*
- *Key spots offered to men who have already made a name for themselves in Rockets*

If you're one of the relatively few trained rocket men in America, your experience will pay off handsomely at Reaction Motors. The first rocket company in America, RMI is now entering its period of greatest expansion, a period that will see far-reaching developments in America's fastest-growing industry. Your participation in RMI's program during this crucial period is your best guarantee of leadership in the industry. In a job like one of those listed below you'll be strategically placed for both achievement and advancement.

1. Senior Design Engineer

Prefer ME or AE degree and a minimum of 6 years experience in aircraft engines or airframes. You should have extensive design experience, including plenty of board time, shop contact, structural design, stress analysis. You will be working directly with design engineers and layout draftsmen on design of light weight, complex structures.

2. Instrumentation Engineer

BS minimum in mechanical, aeronautical or electrical engineering; 3-5 years experience on aircraft engines. Must be familiar with the application of instrumentation to testing of rocket or other aircraft engines, the utilization of currently available instrumentation, or the modification and adaptation of such instrumentation for particular requirements and wide limits of flow temperatures, pressure, thrust, etc.

3. Stress Engineer

Degree in engineering or applied mechanics. Required experience in mechanical design with emphasis on stress analysis; 3 years for an engineer, to 6 years for the senior engineer. Must be able to handle and/or supervise involved analyses—including the effects of dynamic forces, high temperature gradients and high pressure differentials—under conditions where light weight is vital.

4. Product Engineer

BS in ME, AE or equivalent with a minimum of 5 years airframe powerplant experience. Your background should also include engineering and customer contact on technical products and services. You will assume responsibility for organizing a program to apply new and existing powerplants to all types of missiles. 2-3 days of your week will be spent answering inquiries and preparing proposals, 2-3 days traveling.

RMI'S 6 MAIN PROJECT AREAS INCLUDE:

MISSILES • PILOTED AIRCRAFT • LAUNCHING DEVICES • GROUND SUPPORT EQUIPMENT • LIQUID AND SOLID PROPELLANT CHEMISTRY • NUCLEAR ROCKETS

For additional information on these or any other positions, drop a note or send complete resume in strict confidence to:

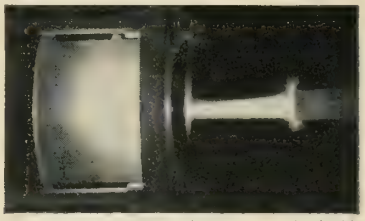
ENGINEERS-SCIENTISTS: TEMPERATURES TWICE AS HOT AS SUN'S SURFACE NOW PRODUCED AT G.E.'S AEROSCIENCE LAB

New "Water Arc" Advances Nose Cone Technology at Missile & Ordnance Systems Department of General Electric

When MOSD became prime contractor for ICBM Nose Cone development, engineers and scientists here were faced with the necessity of creating not only new systems concepts, new components, new materials and new fabrication techniques, but also the *very tools and facilities to evaluate them.*



Meteors may melt on entering the earth's atmosphere, but the relatively thin-skinned nose cone must come through in full functional order. To test out heat-resistant materials capable of withstanding re-entry temperatures, a new instrument was devised under the direction of the research staff of MOSD.

STABILIZED WATER ARC and G-E designed TUNNEL shown during operation. Material undergoing test is held in front of the arc orifice by means of a rod or "sting" running through the tunnel.

3,000 KW used in operating this stabilized arc and evacuation tunnel. (Shown idle.) Has ¼" nozzle diameter. Present plans call for construction of a 3" diameter model, requiring 8,000 KW for operation.

View of fluid-stabilized arc in operation. The liquid revolving inside the glass or plastic cylinder flowing at high velocity offers insulation as well as the material of which the plastic beam is composed.

...the WATER-STABILIZED ARC

How does the new water arc differ from the conventional electric arc? It is controlled–or stabilized–by a whirling blanket of water, which produces a "squeezing" effect, forcing the arc into the shape of a column. By causing a great amount of electrical current to flow across the column, extreme temperatures may be maintained continuously, subject only to the limitations of available power.

Valuable experiments are now being conducted at MOSD's Aeroscience Laboratory with the stabilized water arc. The most advanced heat-resistant materials are subjected to temperatures as high as 25,660°F–more than twice the heat of the sun's surface.

OTHER WAYS OF CREATING HYPERSONIC ENVIRONMENT AT MOSD

G.E. has built the largest, most powerful Shock Tunnel in the country in Philadelphia. Here free flight conditions in the order of Mach 20 can be matched. MOSD also utilizes a high power Centrifuge to test behavior of electromechanical and structural components under gravity loads up to 100 G's.

OPENINGS FOR MEN WHO CAN EXPLORE NEW TECHNICAL AREAS

Engineers and scientists find an ideal research environment at MOSD. They work in small groups on problems of prime scientific interest – in close contact with managers and top specialists.

Located in downtown Philadelphia, adjacent to University of Pennsylvania and Drexel Institute, it is easy to take advantage of G.E.'s Tuition Refund Plan for graduate study.

EXCEPTIONAL GROWTH OPPORTUNITIES:

Organized only in '56, MOSD has been growing phenomenally, and continued expansion is scheduled for '57. This expansion creates many opportunities to rise to positions of higher responsibility and income level. All of the managers of technical groups are themselves engineers or scientists and the majority have come up from within this or other departments of General Electric.

YOUR INQUIRIES INVITED:

If you are a Graduate Engineer or Scientist and have experience in these or related fields:

MATERIALS AND PROCESSES • AERODYNAMICS • AEROPHYSICS • THERMODYNAMICS • ELECTRICAL DESIGN • ELECTRONIC OR ELECTROMECHANICAL COMPONENT DESIGN • STRUCTURAL DESIGN • STRESS ANALYSIS • DATA PROCESSING • SYSTEMS • SYSTEMS TEST • FIELD TEST • VIBRATION • INSTRUMENTATION • CONTROLS • GROUND SUPPORT EQUIPMENT DESIGN • TECHNICAL WRITING • ARMING AND FUZING • INERTIAL GUIDANCE

...send us your resume or, if you prefer, write us for a convenient application form.

Your resume will be carefully reviewed by the MANAGERS *of our various technical components. If qualified, you will be invited to visit our offices and discuss the work we are doing directly with the managers with whom you would be working. All communications will be entirely confidential.*

Mr. John Watt, Professional Placement, Room 590-6

MISSILE & ORDNANCE SYSTEMS DEPARTMENT

GENERAL ELECTRIC

1617 Pennsylvania Boulevard, Philadelphia 3, Pennsylvania

Group, which comprises approximately 50 people, will go to the San Bernardino Air Materiel Area where Col. Philip B. Foote will be designated as Deputy Commander for Ballistic Missiles. Brig. Gen. Ben. I. Funk will remain as overall Ballistic Missiles Weapon System Manager. No successor to Col. Foote as Commander of Maywood has as yet been named.

In his new assignment, Col. Foote will report to Gen. Anderson and receive directional control from Gen. Funk.

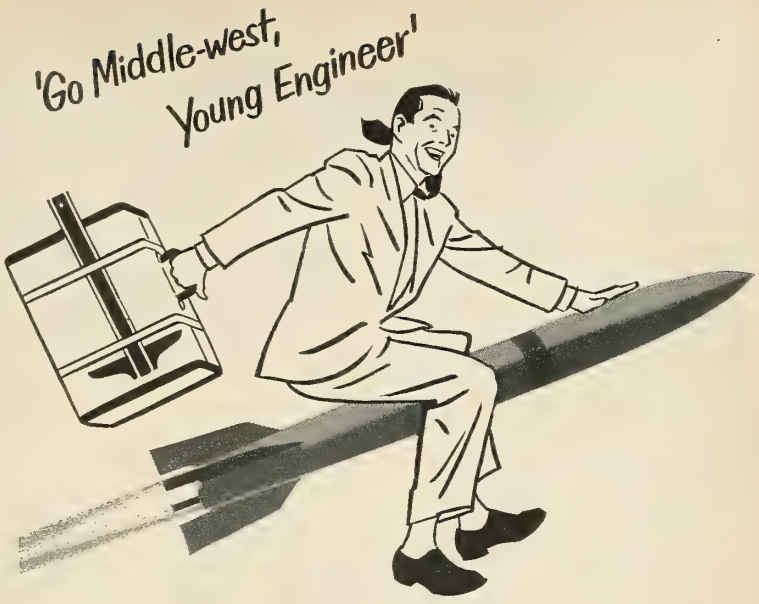
Staff and operating elements of the San Bernardino Air Material Area under the command of Gen. Anderson will render all necessary services to the Ballistic Missiles Weapon System Management contingent when it moves to San Bernardino.

Maywood Air Force Depot will continue to provide administrative services for the time being for the Ballistic Missiles Office at Inglewood in areas of personnel support, accounting, statistical services, transportation, legal advice, and security clearance.

$20 Million Navy Contract or Terrier Launchers

Navy has placed two contracts totalling $20 million with Northern Ordnance, Inc., Minneapolis, Mich. for *Terrier* Launching equipment. This gear is to be installed on the aircraft carriers *Kitty Hawk* and *Constellation,* as on a nuclear powered guided missile cruiser and a new class of guided missile frigate.

Beckman Forms Missile Subsystems Group



Beckman Instruments, Inc. has announced formation of a new contract engineering department in its Helipot Division. Group will be headed by Frederick Marsh under technical director O. C. Bixler.

Role of the new department will be specialization in design and production of electro-mechanical subsystems for aircraft and missiles.

New Martin *Matador* Announced by AF

The US Air Force has announced that the Martin *Matador* ground-to-ground tactical missile presently in operational use is being replaced by a new, improved version of the missile.

The TM-61C incorporates a vastly improved guidance system, designed and developed by the Martin Co. Range

FOR THE FINEST JOB OPPORTUNITIES IN THE GUIDED MISSILE FIELD!

Yes, it's a fact. At Bendix Guided Missiles you'll enjoy living in an attractive community convenient to metropolitan areas and recreational centers, with experiencing job opportunities unrivalled in the guided missile industry.

As prime contractor for the vitally important Talos Missile, Bendix engineers are engaged in the widest possible range of missile work and enjoy unusual advancement opportunities.

There is no question about it—guided missile engineering is definitely the newest and most modern business, and, logically, the best future for engineers is working with a prime contractor on one of the nation's most important missile projects.

So that you may investigate thoroughly the many advantages of becoming a Bendix Guided Missile engineer, we have prepared a thirty-six-page booklet giving the detailed story of the function of the various engineering groups, such as ram-jet propulsion and hydraulics, guidance, telemetering, steering intelligence, component evaluation, missile testing, environmental testing, test equipment design, system analysis, reliability, and other important engineering operations.

If you'd like to combine the advantages of living in the Middle West and an unparalleled chance for professional growth with one of the world's foremost missile builders, just mail the coupon today for your copy of the booklet "Your Future in Guided Missiles".

Bendix—prime contractor for the TALOS MISSILES

Bendix Products Division—Missiles

experienced in the missile and gas turbine fields

SEND FOR THIS BROCHURE

GET THE FACTS about Solar and your triple opportunity...and get them now! Solar currently offers an exceptional opportunity for you to advance rapidly. A new creative engineering group is now being formed for a challenging new project in guided missiles. Many openings also exist in Solar's fast-moving gas turbine programs. The growth potential is tremendous . . . with commensurate rewards in advancement.

Another important advantage is this: you don't get lost in the crowd at Solar. It is a medium-size company (2800 people in San Diego) that has grown steadily since 1927. Personnel policies are advanced, including a profit sharing retirement plan.

Another advantage at Solar is the pleasure of living in California climate at its best. San Diego is warm and sunny the year around, with unmatched recreational and cultural facilities.

For brochure, write to Louis Klein, Dept. E-201, Solar Aircraft Company, 2200 Pacific Highway, San Diego 12, Calif. Why not also send along a resume of your qualifications and education?

SOLAR
AIRCRAFT COMPANY
SAN DIEGO
DES MOINES

of the *Matador* will be substantially increased over the original version according to Martin, enabling a much deeper penetration behind enemy lines and use over wide expanses of water. Traffic capabilities—the ability to control more than one missile in the air at the same time—will be greater, thus making the firepower of a missile squadron much stronger. Accuracy with the new guidance system will be improved.

The system provides complete all-weather operation of the missiles. One of the most important improvements in the TM-61C guidance system is its high resistance to electronic countermeasures. As in other *Matador* missiles, the TM-61C can be launched from rough inaccessible terrain, by the use of rugged, highly mobile launching platforms.

The TM-61C is 39.6 feet long, 54 inches in diameter and has a wing span of 28.7 feet. Operating at speeds of more than 650-miles-an-hour, the missile is capable of altitudes over 35,000 feet. The Martin Co. is producing this version of the *Matador* under an Air Force Production Contract at an approximate cost of $60,000 per missile.

Heath Breaks Ground For New Plant

Ground has been broken for the construction of a new 142,000 square foot plant for Heath Co., manufacturer of electronic equipment in kit form, Robert Erickson, president, announced recently Heath is a subsidiary of Daystrom, Inc.

The modern one-story building will house all of Heath's operations and, upon completion, will be one of the largest plants in the nation devoted to specialized direct mail selling. It will occupy a 16 acre tract in St. Joseph. Mich.

Facilities in the new plant will include specialized equipment for handling mail orders, a product research department with a new anechoic chamber for research with all types of sound equipment and a branch US Post Office.

The company presently operates in six different locations in the Benton Harbor area. Francisco and Jacobus, New York, are the architects.

M-H Reports High Earning

Minneapolis-Honeywell Regulator Co. reports highest first quarter sales and earnings in its history. Sales increased to $76,307,511, compared to $58,166,724 last year.

AN FITTINGS

Stainless, Aluminum, Brass, Steel. All sizes—immediate delivery from world's largest shelf stock. Buy direct from manufacturer. Lower prices—quicker service. Send for free wall charts showing complete line of AN Fittings.

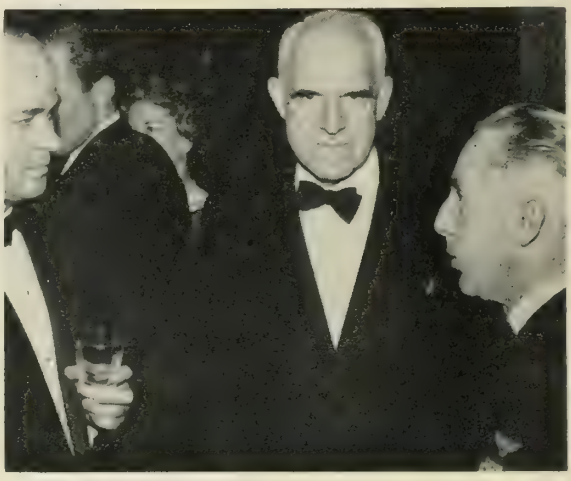
COLLINS ENGINEERING CO.
9050 Washington Blvd., Culver City, Calif.

Largest rocket and satellite exposition ever was sponsored by the American Rocket Society and held at the Sheraton Park Hotel in Washington, April 3-6, in connection with the Society's Spring Meeting. Above is a glimpse of Allied Chemical's booth. Most of the major propellant manufacturers were represented.

Bell's Howard Jansen, right, proudly demonstrates liquid rocket pump to Rocket Society member Darrell C. Romick.

William R. Roennau of the National Capital Section of the American Rocket Society pays visit to Aerojet-General booth. Washington representative, Robert Hirsch, right, was on hand demonstrating Aerojet products.

The three Services and NACA had interesting booths, illustrating their missile efforts and their support on the VANGUARD program.



Among the many materials exhibitors was HAVEG Corporation, displaying their high-temperature insulation materials for missiles and rockets and other applications. Exposition was first of its kind and it was one of the more popular features of the ARS Spring Meeting. The exposition was not open to the general public. Why not?

ARS Spring Meeting hosts, Mrs. Jean Bergaust, Chairman of the National Capital Section's Auxiliary and National Capital Section President, Erik Bergaust, welcome special guest Jimmy Stewart to cocktail party the first day.

Rear Admiral Rawson Bennett, Chief of Naval Research, chats with fellow satellite enthusiasts. Left, Dr. John P. Hagen, and Mrs. Kurt R. Stehling. Right, Dr. A. F. Spilhaus and Kurt R. Stehling.

Rear Admiral John E. Clark, Navy's No. 1 missile man, right and Dr. Thomas Hope Johnson of the Atomic Energy Commission, talk with the Rocket Society's Executive Secretary, Jim Harford, left.

ARS Spring Meeting banquet was held in Sheraton Hall the last day of the meeting. Alan T. Waterman, Director, National Science Foundation, left, at the head table with Meeting Chairman, Andrew G. Haley; guest speaker Athelstan F. Spilhaus, Dean, Institute of Technology, University of Minnesota; and Comdr. Robert C. Truax, ARS National President.

Major General Patrick J. Ryan, right, who gave the Invocation at the banquet, converse with The Reverend Edward L. R. Elson, who gave the Benediction.

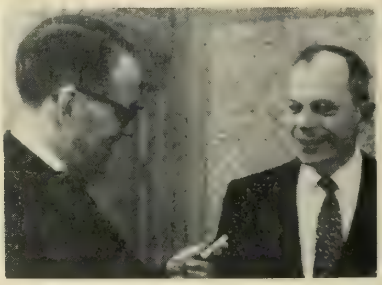
ARDC's Brigadier General Don R. Ostrander and Mrs. Ostrander at head table reception with Grand Central Rocket Co. president, Charles Bartley.

Busy National Capital Section Vice President, Robert Hirsch of Aerojet, right, never stayed anywhere more than a few minutes, his duties ranging from entertaining in Aerojet's suite to supplying press typewriters.

Mr. Rosel H. Hyde, Commissioner, Federal Communications Commission, left, with Commissioner Robert T. Bartley, and Dr. Alan T. Waterman, right.

Washington personality Col. M. Robert Guggenheim, right, had many points to stress during his lively conversation with Commissioner Bartley at banquet.

New ARS Fellow Member Rear Admiral Rawson Bennett, Chief of Naval Research, left, with National Capital Section's Erik Bergaust, m/r Managing Editor; Army Engineer and Fort Belvoir Commanding General David H. Tulley and ARS Program Chairman, Kurt R. Stehling, Naval Research Laboratories' VANGUARD propulsion head.



ARS Spring Meeting banquet was opened in typical Washington style, a color guard marching in with drums beating. The presence of guard, which included one representative from each service, symbolized the importance of missiles to our integrated defense system.

Popular feature was introducing Washington's Cherry Blossom Queen, her court and escorts to the ARS members at the banquet. The meeting was held during Cherry Blossom Week.

As usual, making the rounds of the hospitality suites was tough. Traditionally, Chrysler's headquarters, where Paul Stewart (left) was host, bristled with rocket engineer visitors. . .

. . . and such talented ambassadors as old-timer Lovell Lawrence, left, who said this was "the finest meeting the Rocket Society had ever put on" and should be held annually.

One of the most popular social functions was sponsored by Harvey Aluminum Company. At swanky reception, Harvey's Director of Research and Development, G. Howard Teetor, right, with head of company's Washington office, Keith Linden, welcome guests. Left, ARS' two Bob's: Truax and Hirsch.

The Dean himself, Dr. Theodore von Karman, talks space to Aircraft Industries Association's Jean Ross Howard at Harvey reception.

Rear Adm. John Clark congratulates Bob Truax on a fine meeting. "Thanks, and come again!" Next meeting San Francisco, June 10-13.

people

Lt. Gen. Laurence C. Craigie, former commander of the Allied Air Force in Southern Europe, has joined American Machine & Foundry Co. as asst. to the defense products group executive, in charge of long range planning.

A. V. Cleaver, chief engineer of the Rocket Division of de Havilland Engine Co., has joined the Aero Engine Div. of Rolls-Royce Limited as asst. chief engineer to supervise engineering of rocket motor projects.

Robert M. Hawley has been appointed director of sales and customer relations for Bell Aircraft Corp.'s Weapon Systems Division.

William G. Alexander was named chief engineer at the San Diego plant of Stromberg-Carlson, a division of General Dynamics Corp. He was formerly manager of the high resolution radar section at Westinghouse Electric Corp.'s Air Arm Div.

Paul Frankfurt has been appointed information services officer at the Ballistic Missiles Office of Air Materiel Command.

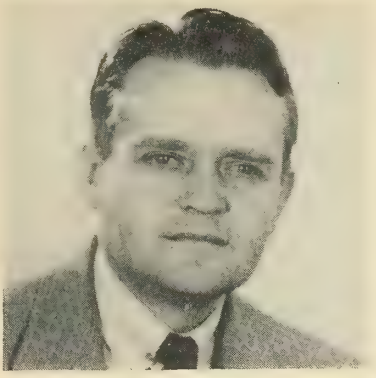
FRANKFURT

Jack Wright has been promoted to Manager of The Garrett Corp.'s Aero Engineering Div.

Haywood C. Smith, formerly manager of the Raleigh Laboratory of American Machine & Foundry Co., has been appointed technical manager, research and development dept., office of the vice president-engineering. He will be responsible for planning and directing new product development for all lines.

Andrew H. Bergeson, vice president-engineering at Stromberg-Carlson, is returning to Washington, D. C. to serve as vice president in charge of the capital city office.

Thomas Allinson has been elected vice president of marketing of Daystrom, Inc.



John R. McLeod, formerly with the Office of Naval Research, has been appointed manager of public relations for the Research and Advanced Development Div. of Avco Mfg. Corp.

J. W. Stack was named director of sales and contracts for the Milwaukee plants of AC Spark Plug Div. of General Motors. He succeeds **Howard W. Brandt,** who is leaving AC to go into business.

Sherman M. Fairchild, founder and board chairman of Fairchild Camera and Instrument Corp., has been elected president.

Robert P. Gira, general contracts manager for Topp Industries, Inc., has been elected a vice president.

John W. Johnson, formerly director of advertising for Chance Vought Aircraft, has been named director of the advertising and public relations department in a reorganization move.

JOHNSON

Richard W. Powell was named asst. manager of the Avionics Div., Aerojet-General Corp.

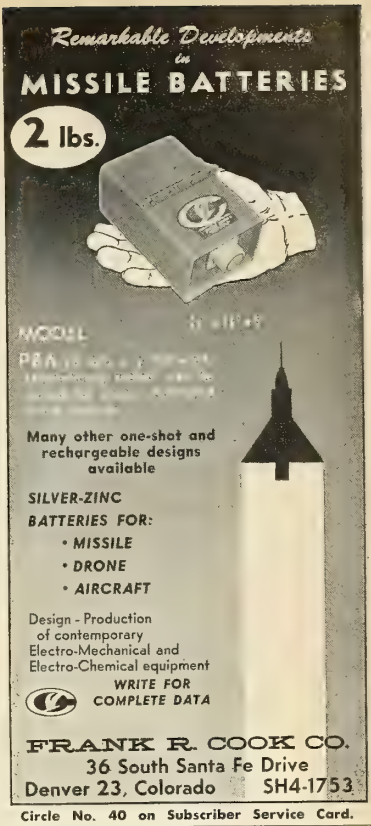
Dr. Marshall G. Holloway heads the new Nuclear Energy Products and Erco Division of ACF Industries, Inc.

Charles E. Burns has joined the Ralph M. Parsons Co., Los Angeles, as manager, Aircraft & Missiles Dept., Project Development Div.

Frank R. Carver will head Hughes Aircraft Co.'s radar development dept.; E. E. Herman will head radar systems dept.; **John C. Bailey** has been named head of scientific and general recruitment for the systems development laboratories.

Frederick A. Henry has joined the Associated Missile Products Corp. as staff asst. to the general manager.

Ronald Smelt has been named director of the New Design Office in the Research and Development Branch of Lockheed's Missile Systems Division.



Alfred Schaff, Jr. has been named manager of Aerojet-General Corp.'s Test and Field Service for the Solid Rocket Plant at Sacramento.

SCHAFT

Joseph M. Johnston has been appointed operations supt. of instruments and components for The Victoreen Instrument Co.; **William A. McCarthy** was named sales manager for the company.

Norman P. Hays will head the new eastern office of Autonetics, div. of North American Aviation, in Washington, D.C.

Circle No. 106 on Subscriber Service Card.

POWER RECTIFIERS. The Christie Electric Corp. has announced the availability of a new bulletin covering their three lines of D C Power Rectifiers.

Circle No. 107 on Subscriber Service Card.

WIRE WOUND RESISTORS. Comprehensive data on construction, characteristics, coating, winding, insulation identification, mechanical strength, terminals and brackets—detailed charts and graphs, is given in a 12 page booklet by International Resistance Co.

Circle No. 108 on Subscriber Service Card.

POTENTIOMETERS MEASUREMENT. Helipot Corp.'s new 30-page booklet takes up a practical approach to predicting, measuring and compensating for quadrature voltage and phase shift in copper-mandrel potentiometers used in AC circuits.

Circle No. 109 on Subscriber Service Card.

WELDED BELLOWS. Belfab Corp. has published an 8 page catalog on welded bellows in stainless steel and similar alloys.

Circle No. 110 on Subscriber Service Card.

AMPLIFIER. 400 and 60 cycle magnetic amplifier data and specifications are given in a 16 page Product Catalog from Litton Industries.

Circle No. 111 on Subscriber Service Card.

JOINTS. Rubber, neoprene and Teflon-lined expansion joints their construction, sizes and uses are explained in a bulletin issued by The Garlock Packing Co.

Circle No. 112 on Subscriber Service Card.

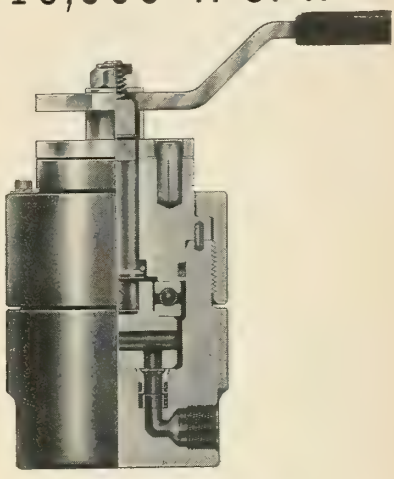
VIBRASWITCH. A device that protects rotating and reciprocating machinery by anticipating any malfunction, is described in a four page bulletin available from Fielden Instrument Division of Robert Shaw-Fulton Controls Co.

Circle No. 113 on Subscriber Service Card.

TRANSFORMERS. A new four-page brochure describing a line of military and special commercial transformers has just been released by Laboratory for Electronics, Inc. and describes, high power pulse, hermetically sealed military and open type military, subminiature binary and toroids.

Circle No. 114 on Subscriber Service Card.

HITEMP WIRE. Characteristics of Altemp Teflon high-temperature, insulated hook-up wire and contained in Catalog T-1 available from Alpha Wire Corp.



Circle No. 115 on Subscriber Service Card.

SOLENOID COIL. Folder 210-3 issued by Hays Manufacturing Co. describes its "Kast-Coil" waterproof, shock-resistant solenoid coil.

Circle No. 116 on Subscriber Service Card.

NEW 'SHEAR-SEAL' VALVE

FOR 10,000 P. S. I.

This new "Shear-Seal" shut-off valve rated for liquids or gases to 10,000 P.S.I. will withstand surges of up to 15,000 P.S.I. without damage to the valve or its leakproof operation. It is designed for a burst pressure of 40,000 P.S.I.

The "Shear-Seal" principle is an exclusive Barksdale development for the control of extreme pressures and has a long history of successful industrial application. Lapped optically flat sealing surfaces of the sealing rings and the mating rotor face are protected by keeping in constant intimate contact; flow is always through the center of the "Shear-Seal" never across sealing surfaces, as in conventional valve design. Sealing qualities actually improve as the self-aligning "Shear-Seals" lap themselves to a more perfect fit with each valve operation. The infinitesimal amount of wear is taken up by a back-up spring.

Valves will be furnished for pipe, tube, AND 150 or any preferred special high pressure connection. For complete information on the "Shear-Seal" design and its application in your particular high pressure valve problem write for "Shear-Seal" bulletin.

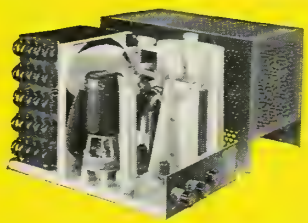
LIQUID COOLING of Electronic Tubes

WITH Eastern COOLING UNITS

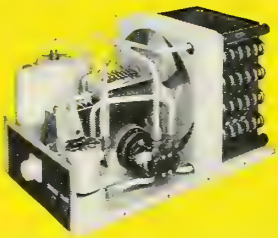
By a sustained program of research, Eastern continuously extends the uses of the latest units in electronic tube cooling, pressurizing electronic equipment, and pumping fuels and hydraulic fluids. Research and testing laboratories, a model shop, and three manufacturing plants provide the specialized equipment and manpower to turn out fully qualified units to meet appropriate government specifications.

From our extensive line of existing units, adaptations of these units, or completely new designs, Eastern can provide equipment to handle your project well. Your inquiry is welcomed.



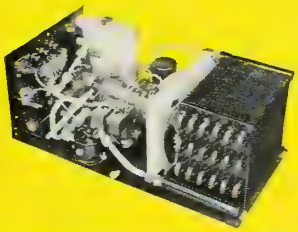
EASTERN INDUSTRIES, INC.
100 SKIFF STREET
HAMDEN 14, CONNECTICUT

Eastern Cooling Units provide coolant liquid for maintaining within safe operating temperature limits liquid cooled electronic tubes or similar devices. The units are completely self-contained and usually comprise such components as heat exchangers, fans or blowers, liquid pumps, reservoirs, flow switch, thermostat, etc.

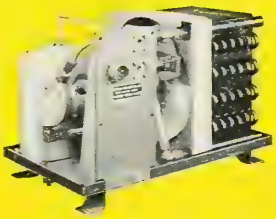


Cooling units can be modified as required for varying conditions encountered in land or sea as well as aircraft service. Almost all units are designed to meet such specification as MIL-E-5400 and MIL-E-5272.

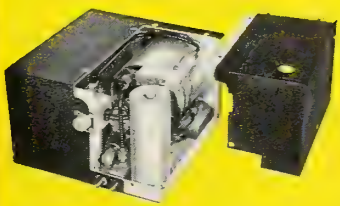
The units shown below are intended only to illustrate the varying requirements which can be satisfied. By utilizing fairly standard components and designs based on broad experience in this field, Eastern is able to provide at minimum cost equipment exactly suiting a specific requirement.



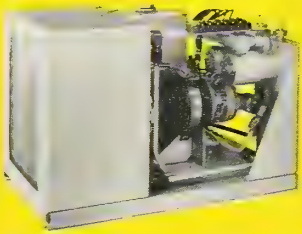
Eastern welcomes your consultation on liquid cooling problems ranging from 200 to 20,000 watts dissipation.



MODEL MB-175, TYPE 200 DISSIPATION: 2,000 watts. ALTITUDE RANGE: sea level to 50,000 feet. POWER REQUIRED: 28 volts D.C. WEIGHT: 25 pounds. SIZE: 10" x 15-15/16" x 10¾" high.



MODEL E/HT-205, TYPE 200A DISSIPATION: 1600 watts. ALTITUDE RANGE: sea level to 5,000 feet. POWER REQUIRED: 28 volts D.C. WEIGHT: 25 pounds. SIZE: 10" x 21" x 10" high.



MODEL MB-177, TYPE 202 DISSIPATION: 1700 watts. ALTITUDE RANGE: sea level to 50,000 feet. POWER REQUIRED: 110 volt, 400 cycle, 3 phase. WEIGHT: 27 pounds. SIZE: 10" x 19 15/32" x 7⅝" high, per JAN-C-1720A, size B1-D1.

MODEL E/HT-210, TYPE 200 DISSIPATION: 1500 watts. ALTITUDE RANGE: sea level to 10,000 feet. POWER REQUIRED: 208 volts, 400 cycle, 3 phase. WEIGHT: 35 pounds. SIZE: 11¼" x 19½" x 12½" high.

MODEL E/HT-200, TYPE 201 DISSIPATION: 1,000 watts. ALTITUDE RANGE: sea level to 50,000 feet. POWER REQUIRED: 28 volts D.C. WEIGHT: 14½ pounds. SIZE: 10" x 10" x 6" high.

MODEL NO. 5-A DISSIPATION: 1,000 watts. ALTITUDE RANGE: sea level to 5,000 feet. POWER REQUIRED: 100 to 110 volts D.C. WEIGHT: 10 pounds. SIZE: 7⅞" x 13½" x 9-1/16" high.

Widening mankind's horizon by conquering

WIDE OPEN SPACES

Men of vision, making the unknown known, have widened man's horizon—advanced civilization. From the great *sixteenth century* exploration of the earth, its oceans, lands and peoples, came knowledge now in everyday use. Today at **CONVAIR**-*Astronautics* scientists and engineers have already embarked on the greatest challenge of the *twentieth century*—man's conquest of the uncharted, unknown and infinite universe. Knowledge gained from solving the mysteries of space will bring mankind untold benefits.

CONVAIR

A DIVISION OF GENERAL DYNAMICS CORPORATION

CONVAIR-*Astronautics, is building a new facility at San Diego, California, which will be devoted to research, development, manufacturing and preliminary testing of the U.S. Air Force's Atlas Intercontinental Ballistic Missile, as well as other projects looking into the future of astronautics.*

NUCLEAR POWER AND ION PROPULSION

"FOLLOW THROUGH"

During more than ten years of pioneering the use of structural adhesives and laminating materials, Narmco has found that the airframe and missile manufacturer requires much more than the simple delivery of materials to his receiving department. He expects more . . . and rightly so! In today's complex business of producing supersonic aircraft and missiles, close supplier-user cooperation is essential. That's why Narmco has developed, and continues to emphasize as a policy, the use of "control" records for every customer . . . no matter how large or small.

Although Narmco inspects and tests products 100% . . . with over 27 separate checkpoints established in the production lines for performing precise, in-process and final control tests . . . Narmco goes even farther in its efforts to provide the ultimate in "down to earth" quality assurance to its customers. Generous physical samples of all Narmco production . . . structural adhesives . . . laminating materials . . . coating solutions and coated materials . . . and putties and resins are randomly selected during production and retained a minimum of 90 days after every shipment.

This makes it possible to provide the customer sample characteristics data on the specific material he received. This procedure affords the manufacturer an important "follow through" service in analyzing his own handling, storage, and use of the product and has frequently resulted in direct savings in manhours and materials when solving "stubborn" production control problems.

This unusual customer service "plus" is another important element in Narmco's assistance to the manufacturer . . . another reason why more and more Narmco products are being used in the airframe and missile industry . . . *doing jobs every day that metals alone can't do!*

NARMCO

PIONEERING THROUGH RESEARCH

Narmco technical field representatives throughout the United States and Canada can assist in solving your structural design problems quickly, efficiently and economically. For immediate assistance, write, wire or phone . . .

phone now!

for a prove-it-yourself demonstration of the Honeywell VISICORDER®

We're sure, once you've seen the fabulous new Visicorder demonstrated, that you'll be as enthusiastic as the thousands of others who have watched the Visicorder in operation.

That's why we're inviting *you* to be the judge . . . to call your nearest Honeywell Industrial Sales Engineer.* He will set up a Visicorder demonstration in your office, plant, or laboratory . . . at your convenience.

The Visicorder, in the short months since its introduction has become the most wanted oscillograph in America. Why? Because the Visicorder records at frequencies from DC to 2000 CPS, with sensitivities that compare to photographic oscillographs. Because the stable, direct-reading Visicorder records are reproducible, and permanent under ordinary usage. Because the Visicorder bridges the gap between mechanical direct-writing oscillographs and photographic-type instruments.

So accept this invitation: Call your nearest Honeywell Industrial Sales Engineer today. He will arrange for you to operate the Visicorder yourself so that you can see for yourself how the Visicorder fits your most complex recording application.

MINNEAPOLIS
Honeywell H HONEYWELL
HEILAND DIVISION
5200 E. EVANS AVENUE • DENVER 22, COLORADO

also ANNOUNCING . . .

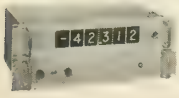
The high-frequency Visicorder galvanometers have been redesigned to provide sensitivity improvements as great as 4 times, and a new 1000-cycle galvanometer has been added. All high-frequency galvanometers shipped after March 15 are to the new specifications.

*Visicorder demonstrators are now based in these Honeywell Industrial Sales Offices: Albuquerque • Altanta • Baltimore • Boston • Buffalo • Cleveland • Dallas • Dayton Denver • Detroit • El Paso • Hammond, Ind. • Hartford • Long Island City • Los Angeles • Omaha • Pittsburgh • Philadelphia • Richmond • San Diego • San Francisco Seattle • St. Louis • Syracuse • Toronto, Ont. • Union, N. J. • Washington D. C. • Amsterdam, Netherlands • and more on the way.

NOW! A REVOLUTIONARY NEW CONCEPT IN PRECISION DIGITAL MEASUREMENTS OF AC, DC, Ohms and RATIOS

New E-I transistorized plug-in modules give maximum flexibility for custom applications with standard off-the-shelf modules.

This latest E-I development provides the maximum versatility in digital instrumentation. From a few basic modules a host of instruments can be constructed. Basic modules never become obsolete. To do new jobs, simply add new modules. Equipment can be easily kept current at minimum cost and engineering.



But versatility is only part of the story. These new modules also boast dramatically new engineering specifications, fully transistorized circuits and numerous other features which were incorporated as the result of our experience with more than 1,000 digital instruments in the field.

Your E-I representative has complete information on this latest E-I development. Ask him about it... today!

Any precision instrument for measuring DC, AC-DC, Ohms, DC and AC ratios can be constructed from these five basic units!

whether it be a DC digital voltmeter...

Model DVA-500

an AC-DC digital voltmeter...

Model DVA-510

or a complete check-out system.

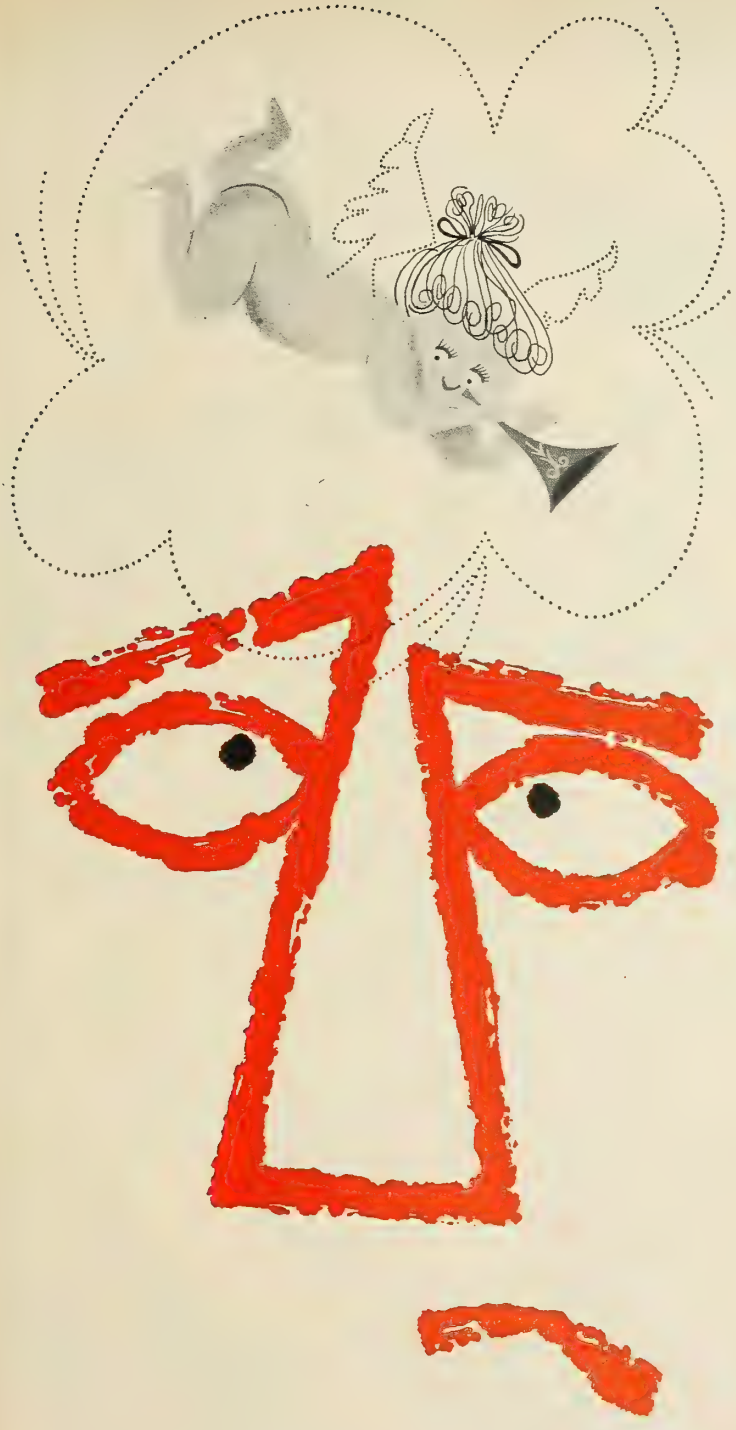
BASIC MODULES

Universal Power Module
Supplies all power and reference voltages for other E-I modules. Power and reference supplies and stepper drive amplifier are transistorized. Powers one or more modules.
Automatic calibration; stability of 0.01% from 40° to 125° F.; input power: 115 volts, 50 to 400 cycles.

DC Switch Modules, 4 or 5 digits
Visual in-line read-out of digits, polarity, decimal point. All contacts accessible at rear panel connector. Front and rear panel input connectors. Power supplied by Universal Power Module.

DC Pre-Amp Module
Input: 1 range scale, gain of 10.
Output: 0.001 to .9999 volts.
Linearity: 0.01%.
Gain Multiplication Accuracy: 0.01%.
Input Power: 115 volt, 50 to 400 cycles.
Drift: 10 microvolts per hour.

AC — DC Converter Module
A fully transistorized AC — DC converter.
Accuracy: 0.1% of reading, or 2 mv.
Frequency Response: 30 to 10,000 cycles.
Range: .0001 to 999.9 volts.
Zin, AC: 1 meg. on the 1 volt scale, 10 megs. on other scales; 20 mmf.
Ranging: Automatic
Reading Time: 3 seconds, average.



Resistance Switch Modules, 4 or 5 digits
Contains balance circuit, bridge ratio arms.
Provides visual in-line read-out digits, range.
All contacts accessible at rear panel connector. Power supplied by Universal Power Module.

New short form catalog now available. Write for yours today!

are you killing that still, small voice?

When that voice prods your professional ego with, "You can do bigger and better things!," do you smother it with a wet blanket of doubt?

And when that same voice whispers to you of a gentle climate where the snow is yours just for the asking and sunshine is always yours for the basking, do you clobber it with the sledge hammer of self-denial?

Don't kill that voice! Its wisdom could lead you to those bigger things, that better life. If you've a mind that can matter in the guided missile field, you'll find the challenge and the excitement you seek at Firestone's new Engineering Lab in idyllic Monterey—Carmel-by-the-Sea... or in Los Angeles with the company's development program for the Army's Corporal.

Here are just a few of the opportunities for ME's:

Aeronautics
Structures Air Frame
Stress Analysis
Machine Design
Materials & Process

Next time you hear that still, small voice, don't reach for your shotgun. Reach for your pen. Write—right now! Let that still, small voice guide you to big accomplishment for you, big happiness for your family!

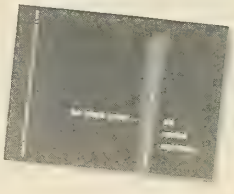
FOR *almost* ANY MISSILE, ANYWHERE ...CREATIVE ENGINEERING BY CLEVELAND PNEUMATIC

Our Special Products Division designs and builds launching stands, test towers, ground-movement vehicles, and storage devices for *almost* any size missile, anywhere.

What do we know about ground-support devices for missiles?



Since 1924, Cleveland Pneumatic has been developing and building cushioning devices. Impact absorbers . . . structural units . . . for large and cumbersome loads.

Our ideas on ground-support vehicles and structures for missiles are firmly based on 33 years of experience.

May we call on you soon to discuss your missile and its ground-support requirements?

Your missile project ...and creative engineering

This new booklet outlines in detail the abilities and facilities of the Special Products Division. For your copy, write on your company letterhead to Cleveland Pneumatic Tool Co., Special Products Division, Cleveland 5, Ohio.

A TYPICAL INTRICATE JOB

Above you see a Mold Core for a solid propellant rocket motor. Previously it had been contour turned and now you see the contour taper being carefully machined by a Diversey master craftsman. He uses a tracer controlled Rockford Hydraulic Planer to machine the aluminum to a fine surface finish.

You have the largest facilities exclusively devoted to your guided missile and rocket hardware problems at Diversey Engineering. In missile metal machining we know what works and what won't. Contact us on your intricate jobs.

This is Not the Time to Cut

Three years ago the U.S. did not have a ballistic missile and none was in sight.

Just lately the Army's intermediate range ballistic missile, *Jupiter*, went the full distance of its immediate objective—1500 miles. It was the first long range U.S. ballistic missile to do so.

The USAF inter-continental ballistic missile, *Atlas*, sits on its launching pad, ready for a first try at the 5000-mile mark. The more sophisticated *Titan* has cut months from its schedule and is reported to be almost as far along as *Atlas*.

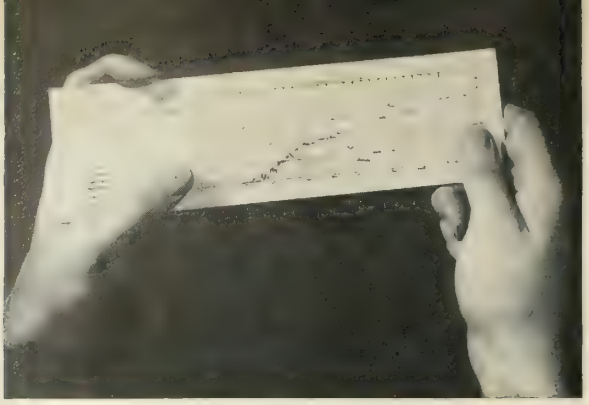
Within the next fiscal year these super-weapons should begin to be fed into America's arsenal. Without doubt they represent the greatest contribution to deterrent military power since the original concept of the USAF Strategic Air Command a decade ago.

This state of the ballistic missile art and science has been achieved in fewer than 36 months from the original go-ahead. It is truly a remarkable and commendable record.

But—

Just at this critical time when the results of a crash program of achievement are being realized, the entire missile program is endangered by an economy ax wielded by Congress.

The same Congress that "viewed with alarm" and gave its wholehearted all-out approval to the crash missile program only several years ago, is now in the mood to chop off the program during its crowning period of producing tangible results.



The same Congress that urged duplication of effort in order to obtain maximum results with greatest speed, is now concerned about overlapping of missile efforts.

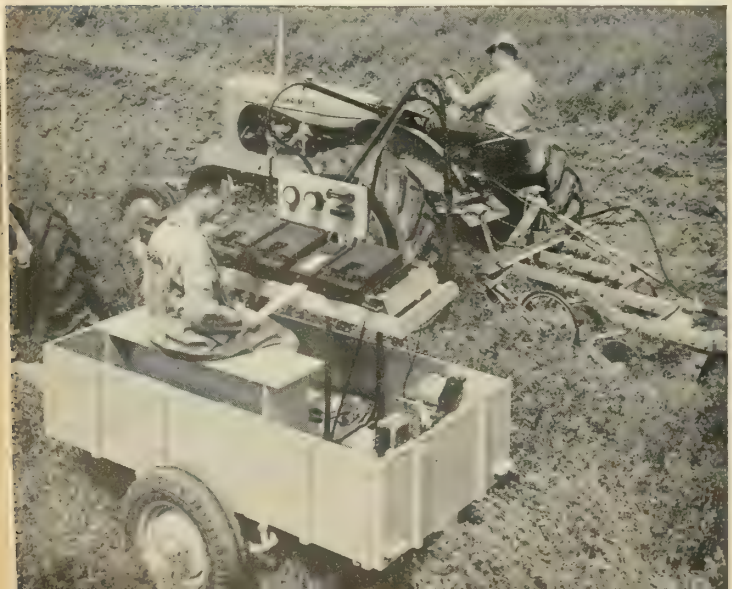
Industry accepted the challenge three years ago. And it was only through duplication—permitting several simultaneous approaches to the problem—that ballistic missiles have reached their present stages of development in such a short space of time.

There are times when economy is extremely short-sighted. This is one of them. It would be foolhardy to trim at this crucial juncture of missile development. It would be like calling off a race in the last tenth of a mile simply because one or two horses stopped running.

Except that the missile race is not a horse race. This is no sports event. We are participants in a world-wide struggle for survival. And the struggle for survival leaves no margin of error for whims or budget-cutting for political purposes. There is no margin left in this struggle for anything except actual achievement in missile power.

WAYNE W. PARRISH

typical data presentation



of Spectrum Recorder. Instrumentation consisted of Accelerometer, Vibration Pickup Preamplifier, and Spectrum Recorder.

CONVAIR CUTS JET LINER ENGINEERING TIME WITH AUTOMATIC SOUND INSTRUMENTATION

The noise problems of the jet age are receiving special attention in development of the Convair 880. Materials and components are being tested for acoustical properties in a new Sound Laboratory using Brush-Bruel & Kjaer instrumentation.

Here the unique Brush Spectrum Recorder performs a complete frequency-spectrum analysis on sounds from 14 to 36,000 cycles per second. Chart records, in one-third octave steps, provide data in most useful form to achieve desired results. **And this instrumentation, operating automatically, saves hours of engineering time.**

Brush-Bruel & Kjaer instruments are available in complete systems for analyzing sound-noise-vibration. Let us help *you* eliminate undesirable noise.

strain measurements speed up field tests

Here Allis Chalmers uses Brush Analyzers and Oscillographs to record variables such as weight and hydraulic pressure variation, drawbar load, axle torque, etc. ***Brush Oscillographs maintain accuracy in such rugged use, provide immediately available chart records to save engineering time.*** Described in booklet "Strain Recording".

Small section of fuselage skin being noise tested in Convair Sound Laboratory. Brush-Bruel & Kjaer instruments are used here to check transmission loss in panels, absorption coefficients of materials, reverberation times, and for general sound tests.

For information call your Brush representative.

Powerhouse of America's major missile programs

Every day at ROCKETDYNE'S Propulsion Field Laboratory, deep in California's Santa Susana Mountains near Los Angeles, rocket engines developing millions of jet horsepower are tuned and tested for their ultimate job—to power America's long-range missiles.

These high-thrust engines—developing more propulsive power than anything before produced—are moving on schedule from ROCKETDYNE for delivery to the Armed Forces. By fall of this year other high-thrust production engines will flow from another plant now being activated by ROCKETDYNE in Neosho, Missouri.

As today's engines are being delivered, ROCKETDYNE engineers are constantly pushing ahead—evolving dramatic boosts in power outputs and engine performance.

This kind of tomorrow-minded engineering—conducted in a private enterprise system—is a keystone in the defense structure of the free world.

As an engineer, you could find no more challenging and rewarding field than Rocketry. Write: ROCKETDYNE, Personnel Manager, Dept. MAR-72, 6633 Canoga Avenue, Canoga Park, Calif. or Dept. MAR-72, Neosho, Mo.

ELIMINATE THE "UNKNOWN" ERROR FROM YOUR THERMOCOUPLE MEASUREMENTS

MODEL RJ 12
(U.S. PATENT PENDING)

Now accepted in most of the nation's missile and aircraft flight test programs, the **ARNOUX "HOT" REFERENCE JUNCTION** is fast superseding ice baths and bridge compensating networks in airborne applications.

Comparative data prove the Arnoux RJ contributes up to 10°F less error, under severe environmental conditions, than other commonly used techniques. Moreover, it requires no servicing prior to flight, and operates indefinitely without attention of any kind.

Regulation of the nominal 250°F junction temperature is within ± ½°F, at constant ambient. Environmental ambient variations of − 65 to +200°F cause less than ± 2°F total drift of the nominal. Maximum spread between junctions is 1°F. MIL E-5272A vibration and acceleration cause negligible error.

Operation of the RJ is simple. Thermocouple leads are soldered to the SPECIAL RED AN INPUT CONNECTOR containing pins of thermocouple alloy. Copper output and power leads are soldered to the STANDARD AN OUTPUT CONNECTOR. Special conversion tables for 250°F junction correction are furnished.

Airborne models available in 2, 4, 8 and 12 channels for use with any thermocouples specified. Size: 3" x 3½" x 4¾". Weight: 1¾ lbs. Power: 28V DC, 15 Watts.

Rack mount models also available for ground applications, with capacities of 24, 48 and 72 channels. Power: 115 V AC, 60 cps.

Get the facts . . . write for APPLICATION NOTE RJ1001, a frank analysis and comparison of the three common reference junction techniques.
For more about the Arnoux RJ, ask for Bulletin 400.

HYCON EASTERN introduces

RAPID ACCESS IN ANALOG DATA REDUCTION SYSTEMS

Two companion units by Hycon Eastern provide automatic high-speed access to selected data in Ampex Recorders and similar multi-channel magnetic tape instrumentation systems.

For Tape Indexing

DIGITAL TIMING GENERATOR, Model 201, generates numerically coded timing signals which are recorded on the magnetic tape throughout the data recording periods, providing a precise digital index in terms of elapsed time. The Generator also visually displays the exact time in hours, minutes and seconds as illuminated digits. MODEL 206A, A MINIATURIZED VERSION OF MODEL 201, IS SPECIFICALLY DESIGNED FOR AIRBORNE USE.

For Tape Search

MAGNETIC TAPE SEARCH UNIT, Model 202, operates during data reduction periods. On the basis of time indices recorded on the tape by the Digital Timing Generator, this instrument automatically locates and selects for controlled playback the tape data included between a "sequence start time" and a "sequence end time" specified by panel dial settings. The time index is visually displayed as illuminated digits on a small separate panel which may be remotely located for convenience.

DESIGN FEATURES

TIMING INFORMATION occupies only a part of the available bandwidth on a magnetic tape channel . . . remaining bandwidth in timing channel may be used for other purposes; e.g. to record other digital or analog data, or as a voice channel.

TAPE SPEEDS of 60, 30, 15, 7½, 3¾ or 1⅞ inches per second may be used for recording. For playback, any one of these 6 speeds or a high-speed search rate may be used. Other speeds may be incorporated as required.

TIMING TRACK contains a combination of complete time numbers in hours, minutes, and seconds together with interpolation pulses so that time can be measured with a resolution of a few milliseconds.

ADDITIONAL SIGNALS for recording, recovery and display may be assigned to arbitrary control functions in the data system.

FORWARD OR REVERSE directions may be used for tape search at either the high-speed search rate or any one of the 6 normal record play back speeds.

MOUNTS in any RETMA standard 19" relay rack.

WHY DOUGLAS ENGINEERS AND SCIENTISTS GO FURTHER . . .

At DOUGLAS, you'll work to expand the frontiers of knowledge in today's most advanced missiles program

1. Nike 2. Honest John 3. Sparrow 4. Thor IRBM 5. Secret 6. Secret 7. Secret 8. Secret

It's no secret that we're in the "missile business" to stay . . . with sixteen years behind us and an ever-expanding future ahead

There can be no mightier challenge than to be assigned to any one of the major projects now under way in the Douglas Missiles Division.

Some – like Nike and Honest John – have pioneered missile development. Others on which Douglas engineers are engaged are extending the horizons of present-day development . . . cannot be mentioned for reasons of national security.

These are the projects that require engineers who are looking far beyond tomorrow. You will use all of your talents at Douglas and have the opportunity to expand them. Your only limitations will be of your own making. Douglas is an engineer's company . . . run by engineers. Make it your working home and build an important and rewarding future in your field.

Would-Be Rocket Engineers Again

To the Editor:

I am concluding my junior year in high school and have been greatly interested in rockets for about 6 years. (My highest dream is to some day be along on the first flight to the moon or some near-by planet.)

I think I am most interested in propulsion and would like to do research on new types of rocket propulsion, or try to perfect today's fuels. I have tried to prepare myself for such work by following high school outlines for most technical or engineering schools. I am very much perplexed on deciding what to major in in college to prepare myself for work in this field.

Aeronautical engineering, physics, engineering science and chemical engineering has all been suggested to me. As a guidance project we are to write to some known expert and ask for advice on our own problem. So, after reading your book I chose you to write to. If you find time to return a letter I would like to know what special field you would suggest I study in college.

As to college I am considering MIT and hope I will be accepted. I have maintained a straight A average in all subjects and have participated in extra curricular activities, such as: baseball, football, basket ball, German Club and others.

I would very much appreciate an answer to the previous questions and if you approve my selections of colleges. Since I could only attend MIT on some sort of a scholarship, I am considering Case Institute of Technology and Carnegie Institute of Technology.

If you know of any others I would appreciate hearing of them.

David Bonn
Deshon Manor
Butler, Penna.

You are one of many thousands of American youngsters with a common problem. If you are 17 years old you can and should join the American Rocket Society as a student member. Write to them for information. The address is American Rocket Society, 500 Fifth Avenue, New York 36, N.Y. Do not hesitate to write to the universities mentioned in your letter, such as MIT and Purdue. Also, why not try Johns Hopkins? We are preparing a special issue on education and training for the missile age, to be published this fall. We hope this will be of value to you. Our personal advice—while you are waiting for the first moontrip—concentrate on mathematics and chemistry.—Ed.

Says He Thought Of It First

To the Editor:

I noted Winzen's comments on the introduction of the Balloon-Launched Rocket in 1947. In a rather science-fictionish article titled "Electronics & Airpower" which ran in the September-October-November, 1944 issues of "Radio-Craft," I made a similar suggestion. Why are not rockets lifted by balloons to 15 or 20 mile heights and then triggered off by aneroid type detonators to send them up another 10 or 20 miles.

This was probably never seen by rocket men, but it looks like it was a pretty good question at that, even though I should have said "100 or 200 miles."

Ted Powell
42 Nassau Rd.
Great Neck, L. I.

Missile Help for High Schools

To the Editor:

Under letters I notice correspondence on high school rocket courses with kudos for the University of Maryland. We have a program under way in which twelve local high schools are participating. I think it's important to interest high schools in rocket work and other scientific work and provide opportunities for them. Maybe m/r can sparkplug such projects.

The item on Page 52, about the Russian drawings of the *Mouse* satellite are of interest to me and I'm glad to know that they are giving me credit . . . Your whole series about underwater missiles is excellent and I can't praise it enough . . .

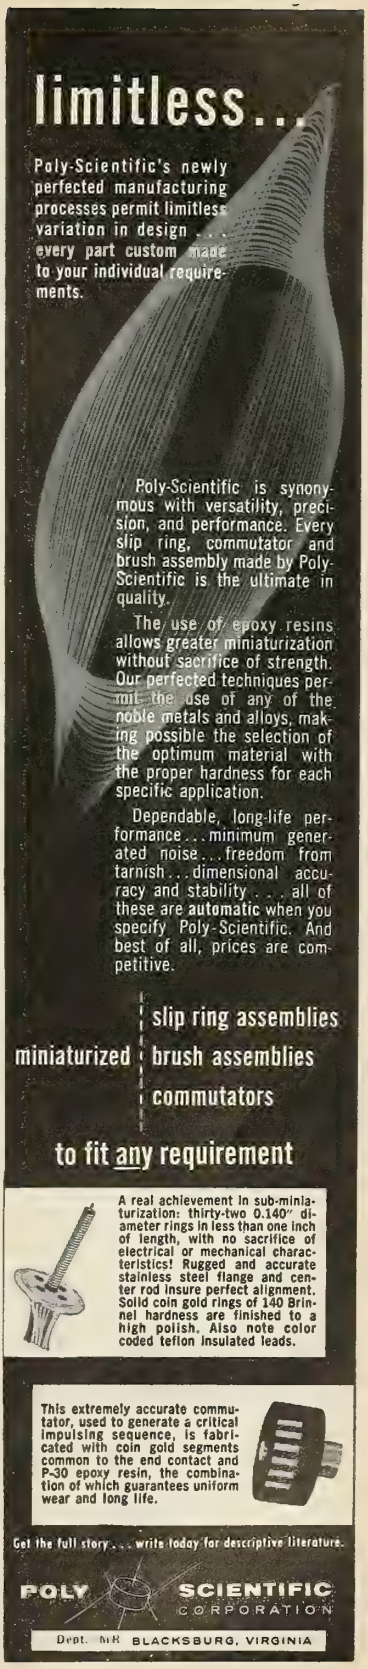
S. Fred Singer
University of Maryland
College Park, Maryland

A Need for m/r

To the Editor:

I have recently seen your magazine and I would like to let you know that I feel it is very informative and that there is a definite need for it in the missiles and rockets field.

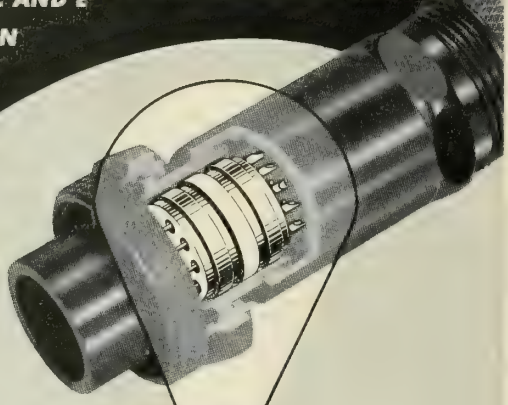
N. E. Miller
Murphy & Miller, Inc.
1326 S. Michigan Ave.
Chicago 5, Ill.



Donner and Blintzon

To the Editor:

We have followed with interest the correspondence in your journal on the subject of the acceleration in free fall of Lintz basalt. We feel obliged to draw to your attention the fact that in the particular case of this phenomenon the Russians may have scored a first. Whereas the paper of Brush, allegedly pioneering the work in this field, appeared in the Proceedings of the American Philosophical Society, Vol. 65 (April 23, 1956), we must report that in the journal Soviet Transactions on Basalt Science, Vol. 17 (April 1, 1924), not only was the constant generation of heat in Blintz basalt reported as exceeding that which is possible from radioactive effects but also the acceleration of Schmaltz basalt was recorded as having been measured at 994.4 cm/sex^2 (for samples of Schmaltz basalt 99 and 44/100 per cent pure). Furthermore, for samples of Schmaltz basalt 99 and 77/1000 per cent pure the acceleration was reported to be 997.7 cm/sex^2.



Soviet experiments on these materials were prematurely discontinued (probably due to a grave shortage of Soviet Schmaltz basalt).

It may be pertinent to record, moreover, that the writers have examined the possibility of a quantitized theory which may bear upon inertial and gravitational equivalence in the light of the reported data. We obtain a satisfactory field theory,

in agreement with the experiments, provided we postulate a graviton (the Blintzon) and an anti-graviton (the Schmaltzon) for which, in the classical limit, the following results hold: First, there are equal numbers of Blintzons and Schmaltzons in the universe. Second, the equivalence principle of gravitational and inertial mass is valid except for mass in which the parity principle for Blintzon and Schmaltzons is violated. (This seems to be the case for the material used in Brush's experiments.) Third, anti-gravitation is possible only for sufficiently pure Schmaltzy material.

We are presently concerned with the corresponding calculations for Blintz basalt but are not yet prepared to communicate our preliminary results.

R. M. Baer

Lafayette, Indiana

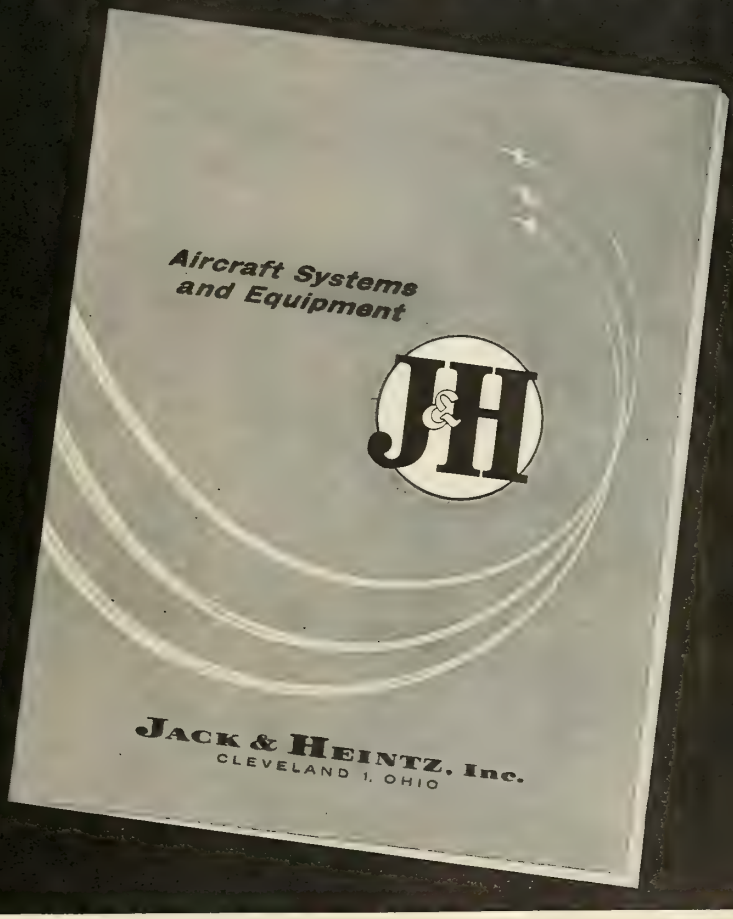
We appreciate the author's interest in m/r but feel we should point out to them that in their deliberations they completely overlook the catalytic effects of a colloidal suspension of emulsified butyrates in proteinaceous-lactic acid medium which was reported by Kreplach and Bupkiss in the Journal of Comparative Oblivion, Vol. XXX, June 31, 1919 —Ed.

Anomalies on Lintz Basalt

To the Editor:

I have read all the letters dealing with Lintz Basalt with considerable interest and a bit of astonishment.

I cannot help but feel glad that your attitude with respect to the whole "anti-gravity" run is a good one. I think you will be interested in the following and I hope that this will contribute somewhat to a critical look at this question:



Concerning gravity—anomalies on Lintz Basalt.

For a critical consideration of such anomalies claimed to have been observed on Lintz Basalt it is, of course, sufficient to apply the Newtonian concept of gravity.

Isaac Newton in 1687 gave the quantitative relationship for gravitational interactions: $F=GMm/r^2$, where F= Force, G = 6.68×10^{-8} dyne, the universal constant of Gravitation, M= the mass of the earth, r= the earth's radius and m= the mass of the test body. The three factors, G, M and r (the minutest changes of r in experiments with pendulums or falling bodies can be ignored) are constant and can therefore be symbolized by one factor, $g = GM/r^2$. The formula for F now reduces to F=gm, which is the force of the earth on a body on its surface, commonly called weight, or seen from another aspect, a fundamental formula of mechanics. This last formula shows that the acceleration g of a falling body is determined only by these three factors, G, M and r, and is therefore independent of its mass m.

The radius of the earth is known with a remarkably high degree of accuracy. The change of g with varying altitude, respectively the acceleration g_a is given at an altitude a by: $g_a = g(1 - ka)$ where g is the acceleration at sea

Simplify design and purchasing with this new aircraft equipment guide!

JACK & HEINTZ AIRCRAFT ELECTRIC EQUIPMENT

Guidance system check-out equipment program for the Army Redstone Missile was carried out by DFI. Actual equipment illustrated below

How to pitch a perfect "strike"

. . . 200 MILES AWAY

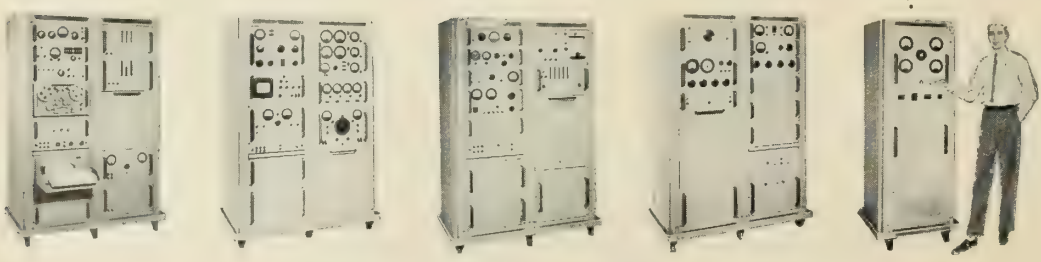
It's tough enough to pitch a baseball 60 feet, 6 inches, and get a strike. Imagine pitching a multi-ton rocket 200 miles . . . and guaranteeing a strike every time.

It's no accident . . . Such pin-point accuracy comes from a precision-built, self-contained guidance system, developed by U.S. Army scientists and integrated into Redstone Missiles by Chrysler Corporation Missile Operation.

A very small error in guidance, though, means a very large error in target accuracy. So a precise, highly reliable test system for "guidance check-out" had to be developed.

And it's no accident that Designers for Industry was given the responsibility of producing this vital check-out system. During our 22 years, we've built a reputation for performance on many projects critical to national defense. The unusually tight schedule set by the Army for this program was met by closely coordinated teamwork between Chrysler and *DFI*.

Unusual results were achieved beyond the immediate program requirements. For example, as part of a complete A.C.-D.C. Power Supply, a special control for a standard rotary inverter was needed. This new control gives *regulation of 30 parts per million* at 400 cycles under steady load — and feed or absolute regulation of 0.05 cycles in 400 under varying load and feed.



Production of such equipment has again demonstrated our ability in this and allied fields. We can offer power supplies or inverters for other applications, *including inverters for airborne uses.*

POWER SUPPLY

Input: 220 Volt, A.C., 3 Phase.

Output: 26-32 Volt, D.C. variable; regulation 1%, ripple factor less than 1%, 0.56 KW.

115 Volt, A.C., 3 Phase, 400 cycle, regulation 0.05 cycles for varying load, 30 parts per million for "steady state", 750 VA.

Representative samples of test equipment produced by DFI

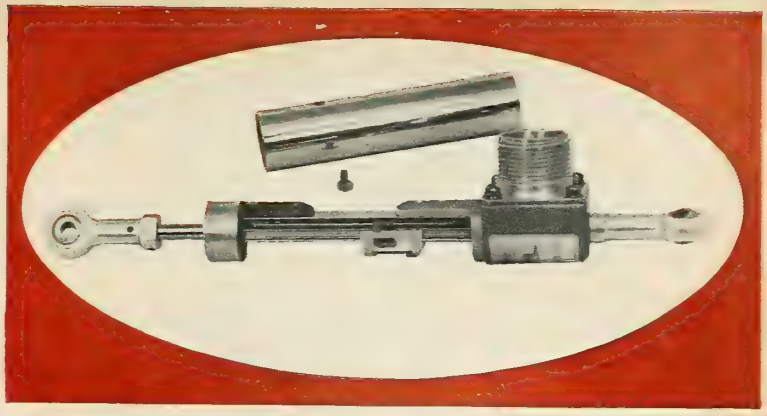
level and k is a factor of proportionality, approximately = 3.10^{-7}, that is, if the weight of 1 kilogram is raised 1 meter, the change in weight is .3 milligrams. For weighing experiments of utmost accuracy it is therefore necessary that the two masses be arranged at exactly the same level. On the other hand, by arranging alternately the two masses at different levels, the factor k can be determined accurately.



G and respectively g are determined with torsion balances (such a torsion balance was used in 1798 by Cavendish for the first determination of G), pendulums, balances and gravimeters. Gravimeters (today mainly used for geophysical explorations, e.g., of oil fields) are in principle spring balances of extremely high sensitivity, the measuring system of which weighs only some grams or fractions of a gram.

Newton showed with pendulum experiments that for a given length of the pendulum, g or the swinging time, was independent of the material of the bob. The accuracy of his experiments was about 1 part in 10. F. W. Bessel, (1), improved the accuracy of these measurements to about 1 part in 10^5 and obtained the same results, that is, no influence of the material on g could be measured. R. V. Eotvos (2) and coworkers (3) improved the accuracy of the torsion balance used by him to such a degree, that G respectively g could be determined with an accuracy of 1 part in 10^9. All his measurements showed that g is not influenced by different kinds of substances, e. g., metals, liquids, organic substances etc. Furthermore he showed that g is not influenced by the radioactivity of the test material. He too showed that the "absorption" of the earth along its axis with respect to gravitation would be less than 1/800 of the total attractional force of the earth. Q. Majorana, (4) obtained the same results.

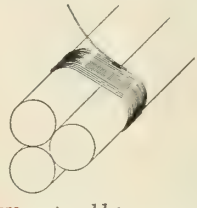
(5) It was claimed by Ch. F. Brush, based on experiments, that the proportionality or identity between gravitational and inertial mass was not fulfilled; or what is the same, an influence of the material, for example Bismuth crystals of the test body, was present on g. However, it was shown by H. H. Potter & P. Philipps, (6), Wilson (7) and A. Berroth (8) that these claimed discrepancies or results were erroneous. Furthermore, P. R. Heyl (9) showed that the gravitational interaction of cystals: Quartz, Zirconium, Turmalin, Gypsum etc. was independent of the orientation of the different crystal axes. P. Zeeman (10) obtained the same, that is negative results, with spheres made of natural quartz crystal, P. Landolt (11) on the other hand could show that no influence existed of chemical changes on the gravitational interaction. Finally, E. W. Shaw and N. Davy (12) proved experimentally that there is no influence of temperature on the gravational interaction. The discrepancies in some of these experiments were all of a minimum magnitude, i.e. less than about 10^{-8}.

Keeping in mind these experimental facts and referring again to the two formulas, there remains only one very hypothetical possibility for the discrepancies claimed by Ch. F. Brush, and that is a change of G.

P. M. Dirac (13, 14) proposed the hypothesis that G is not a constant but undergoes a variation in magnitude with

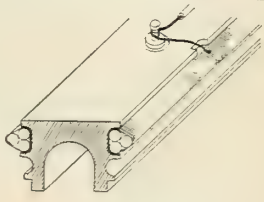
Ruggedized, Precision Potentiometer

New construction... environment-proof performance



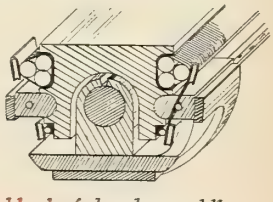
Constantly increasing environmental problems create a demand for precision potentiometers that combine the ability to produce high-level intelligence signals with construction rugged enough to meet the most severe conditions.

Humphrey high-temperature rectilinear pots meet this challenge with unique design features.



Bonded construction has simplified and ruggedized internal connections. Resistance elements and rail are bonded integrally to the frame. Made with high temperature glass insulated terminals for internal lead connections and hard soldered connections to connector pins for reliability.

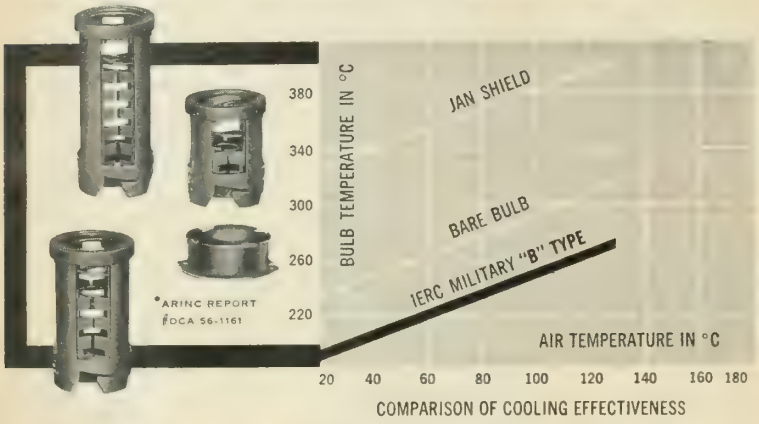
New design for the brush carriage holds brush pressure accurately throughout the length of the resistance element. Withstands vibration at 25G from 20 to 2000 cps without discontinuity or excessive noise.



All standard models are guaranteed to operate continuously at 350° F; special models at 400° F and up to 500° F. intermittent. Linear motions can be measured with an output signal level of more than 100 v/″ and resolution to less than 0.001″.

Micro spot weld tap connections (guaranteed single turn connections).

Bonded construction of the resistance element to frame gives new ruggedness.



Double-leaf brush straddle mounted on trunnion pin, fitted into brush carriage.

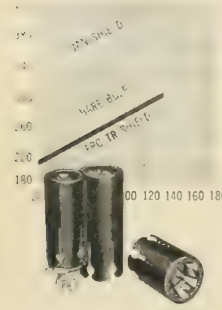
NOW—increase electron tube life *12 TIMES!



COMPARISON OF COOLING EFFECTIVENESS

Exclusive IERC Tube Cooling Effectiveness Provides Greatly Extended Tube Life And Reliability!

Though electronic engineers know that even the *slightest* tube temperature reduction improves tube life, the greatest success enjoyed in obtaining *extended* tube life has been when IERC Heat-dissipating Tube Shields have been specified and used. Results show that extensive gains in tube life and reliability are easily achieved—that tube operating temperatures are reduced as much as 150°C—that IERC's Military Type "B" shield is the *only effective answer* to obtain these benefits in *your* new equipment. Positive shock and vibration protection plus electrostatic shielding is provided. Graphs show temperature reductions when IERC "B" and "TR" shields are used with 6005 tube operating at full plate dissipation. Meets or exceeds Mil—S—9372B (USAF).

PATENTED OR PATS PEND CROSS LICENSED WITH NORTH AMERICAN AVIATION, INC

Retrofit For Maximum Tube Life

No modification is required with IERC "TR" Type Heat-dissipating tube shields! TR's fit easily to existing JAN sockets—greatly extend tube life through excellent cooling and retention against shock and vibration.

Complete IERC literature and Technical Bulletins sent on request. WRITE TODAY!

letters

respect to time. However, such changes were supposed to occur only during cosmic times. P. M. Dirac discarded his theory in later publications, thinking it too extreme. P. Jordan (15) and many other cosmologists used this concept of a variable "constant" of gravitation, but only for purely theoretical considerations and theories. Therefore this concept is out of the question for short-time measurements of G and g.

Finally, such a gravity anomaly as is claimed to occur on Lintz Basalt would be a contradiction to the observed, measured and so empirically proven identity between gravitational and inertial mass. This identity represents the fundamental concept of the general theory of relativity or the Einsteinian theory of gravitation and expressed in his principle of equivalence. A. Einstein explained this principle in a more condensed and simpler form: gravitational and inertial interactions are determined by the same characteristic of matter, that is mass.

It would be difficult to deduce and describe why this same factor mass should behave in a different manner with respect to gravitational and angular or linear accelerations.

New from Clary!

"Guided" valves for guided missiles!

high-pressure line valves with 5 choices of actuation!

Now you can "guide" the operation of these valves with 5 different actuation systems–solenoid, pneumatic-hydraulic, manual, explosive or shuttle! A truly complete line of high-pressure line valves.

Here at Clary, our years of experience in manufacturing guided missile components – gyroscopes, servo-actuators, propellant valves, telemetering transducers – now enable us to bring you these high-pressure line valves built with the same precision. Our extensive inspection and quality control guarantee the maximum reliability required of missile components.

When **precision, reliability** and **versatility** are factors in your plans, please call on Clary for complete services, including:

DESIGNING AND TESTING to established specifications and envelope drawings.

PRODUCTION-ENGINEERING of components and complete assemblies covered by your prototype, sketches or drawings.

MANUFACTURING of precision components to established drawings and specifications.

THE FLIGHT HEARD 'ROUND THE WORLD

Recently three B-52 bombers flew around the world in 45 hours and 19 minutes. They were only specks in the vastness of the sky, yet they were in voice-contact every mile of the way—with SAC headquarters in Omaha, with each other, with bases along the route and with the KC-97 tankers that refueled them in the air.

Their speed-of-light contact was the AN/ARC-21 liaison communications set in each of the ships. This is a long-range, pressurized, high-altitude airborne system, capable of world-wide communications. It may be operated by the pilot, so no radio operator is needed. It is characterized by minimum training requirements, simplified maintenance, high reliability, positive channel selection —with a choice of any 20 of 44,000 frequencies.

In this as in other ways, RCA serves our Nation's armed forces. RCA scientists and engineers are constantly creating, designing and producing new and better electronic systems and equipment.

PINPOINT PRESSURE PATTERNS ABOVE 5000°F

Proven Design — new, high temperature pressure transducer uses same catenary diaphragm and tubular strain cylinder as NORWOOD CONTROLS' highly successful air-cooled models. Immune to external vibration; mounts flush with negligible change in volume of pressure chamber; extremely high frequency response, flat to 10,000 cps.

Withstands ultra-high temperatures — designed for use in rocket and jet engines, high temperature chemical reactions, etc. Efficient water-cooling system enables diaphragm to withstand gas temperatures above 5000°F. Heat transfer rate 11 BTU/sq. in./sec. with 85°F temperature rise of cooling water.

Corrosion resistant — All exposed parts of stainless steel, can safely be exposed to highly oxidizing conditions.

Full Scale Pressures — 0–1000 and 2000 psi ranges with 1% of full scale accuracy and excellent temperature compensation. (Other ranges available on request.)

Write for Data Sheet A157-2 on Model 107 and Data Sheet A257 covering Norwood Controls' air-cooled transducers, which have recently been substantially reduced in price.

book reviews

Realities of Space Travel. *Edited by L. J. Carter, ACIS, (Putnam & Co. Ltd., 42 Great Russell St., London, W.C. 1, Price: £1.15.0 ($4.90) plus postage.)*

A fully illustrated 430-page book consisting of twenty-four authoritative articles by sixteen recognized experts on different aspects of space flight including: "The Satellite Vehicle," "Interplanetary Flight," "Physical Factors in Space Flight," "Biological Aspects of Space Flight." Each chapter was originally a paper presented to the British Interplanetary Society.

Among the contributors, Col. P. A. Campbell, USAF doctor, who covers the aeromedical and biological aspects of flight above the atmosphere; L. J. Carter, secretary and journal editor of the BIS, writes about the US Naval Ordnance Test Station at Inyokern and about Woomera; A. V. Cleaver covers rocketry aspects up to a program for achieving interplanetary flight in 33 pages.

L. R. Shepherd, reactor physicist from the UK Harwell Atomic Energy base contributes on the nuclear rocket, cosmic ray hazards and a forward-looking piece on interstellar flight, as well as a clear statement of the basic principles of astronautics; N. J. Bowman of Standard Oil gives his views on food and atmosphere control problems in space vessels.

Professor S. Fred Singer of Maryland University discusses the present practical minimum orbital instrumented satellite. That familiar UK spacewriter Kenneth Gatland in collaboration with A. M. Kunesch and A. E. Dixon, covers the minimum satellite vehicle, while, T. Nonweiler, aerodynamics lecturer at Cranfield College of Aeronautics writes about aerodynamic braking during the descent from orbit.

The book contains useful historical and useful reference curves. It is not for the advanced specialist, but it gives a sound statement of present knowledge in terms that the technician in any trade can understand—the nontechnical can learn almost as much simply by skipping the sums.

The Sun. *By Giorgio Abetti, translated by J. B. Sedgwick, 336 pp. 147 illustrations, 97 figures. $12.00. Macmillan Co., New York.*

Professor Abetti needs no introduction to professional and amateur astronomers. An earlier version of "The Sun" was the recognized text on the subject since its appearance in 1934. A revised and enlarged edition appeared in 1951. This edition was further expanded in 1954 and now makes its first appearance in English as translated by J. B. Sedgwick.

This book evolves from techical data and theories commensurate with interests of the professional astronomer, but is presented in a form intelligible to the layman. Methods of observation of the sun are explained by presenting, with figures and photographic illustrations, the evolution of modern instruments. Spectroscopes, spectrographs, spectroheliographs, spectrohelioscopes, and auxiliary instruments become familiar and meaningful.

The familiar sun spots appear in a new light. Their origin, life cycle, vicissitudes and effects are clarified. Sun spots are generally known for their adverse effect on wireless communication. Apparently they are insignificant in determining the sun's rotation period and its physical behavior.

Perhaps one of the most interesting subjects is the physical constitution of the sun. A chapter of the book is devoted to this subject. In suport of the concept of the sun's physical make-up, the Corona, Chromosphere, Reversing layer, and the Solar Interior theories and interpretations of various phenomena are presented in brief, straightforward fashion supported by numerous figures and illustrations.

The reader will appreciate the extensive studies of the sun. The value of these studies become obvious. The importance of data currently obtained with the aid of rockets will be apparent and the magnitude of knowledge obtainable from satellites is made clear.

Professor Abetti in this book has presented such a comprehensive treatment of this complex subject that not only will it hold the layman's interest, but it will also provoke thought and study by those in technical and scientific fields.

Galactic Nebulae and Interstellar Matter. *By Jean Dufay, translated by A. J. Pomerans, Philosophical Library, New York. $15.00.*

The author, who is director of the Lyon and Haute-Provence Observatories, has succeeded in presenting a most interesting and a thoroughly authoritative book on the study of the diffuse matter in the galaxies. The book provides one of the most complete accounts available of the many diverse phenomena involved in the study of interstellar matter. The book has vocational merit, since it is written for professional astronomers as well as those generally interested in the subject matter.

In part I the types of spectra produced by the atoms and molecules in space are classified and explained. There is also an account of radio emissions from parts of the Milky Way. Part II is devoted to the solid particles of space and the dark nebulae, while Part III explains modern ideas of the physical conditions prevailing in interstellar space and includes a theory of stellar dynamics. In Part IV the behavior of diffuse matter is examined, and the problem of intergalactic absorption is discussed.

In addition to the many illustrations the book is beautifully indexed. It carries a substantial bibliography.

Thinking By Machine. *By Pierre de Latil. Houghton Mifflin, Boston* $5.50

The words automation, electronic brain and cybernetics are now part of our common vocabulary but few people have realized the full implications of the last ten years' progress in the development of self-governing machines. This book describes the principles that make these complex machines possible, as well as the fundamentals of their construction. The book is of great value to electronics and guidance engineers.

This is also a book for those in other fields. Research workers in biology, neurology and other such specialties will appreciate the philosophies and precepts introduced by the author.

Most of all, perhaps, industrial managers will benefit from careful study

for the development of reliable automatic control and computing devices

ATCOTRAN

DIFFERENTIAL TRANSFORMER

EXPERIMENTAL KIT

The research engineer can set up and operate seven different standard differential transformers . . . coils, armatures, and shafts . . . to convert precise variations in position to a proportional electrical signal. Range covers from ± .01″ to ± 2.5″. Flexure plate and clamp, which positions coils, and demodulator are included.

Kit also contains 32-page TRANSDUCER HANDBOOK containing the most complete and up-to-date information on the theory, development, and application of differential transformers. Profusely illustrated with charts, drawings and circuits.

List price of Kit contents is $324.00. Introductory offer . . .

HOW SMOOTH CAN YOU GET ?

Select the new Lyndon non-friction, non-hydraulic damper and you'll select the ultimate available for protection *against all undesirable outside forces.*

Through utilization of the self-contained eddy current principle, the Lyndon damper permits use of any variable or constant flow of linear or rotary force *in the smoothest, most trouble-free manner yet devised.*

Created specifically to fulfill the need for a more reliable damper with optimum linear relationship, Lyndon's damper *is thoroughly field tested,* is unaffected by operating temperatures from −100°F. to+300°F. and is qualified in accordance with specification MIL-E-5272A.

of the theories presented. Many professional engineers may find this a provocative book. They may not always agree with the author but they will probably agree the book is a fine contribution to the sparse literature on cybernetics.

Man into Space. *By Hermann Oberth, 226 pp. $4.50, Harper & Brothers, New York.*

For those who have made their reservations for the first lunar flight, Professor Oberth gives details on what the well-dressed space man will wear. Also covered in this spacecraft guide are satellite rockets, space stations, his famous space mirror, electric space ships and a vehicle for use in getting around on the moon.

Oberth, the father of space flight, dates his interest in astronautics back to 1922 when he wrote his thesis on the subject. Later he published a German best seller "By Rocket to Interplanetary Space." He started work on a research project involving design of the V-2 in 1938 at the Technical Institute in Vienna and later moved on to the rocket laboratories at Peenemunde under von Braun.

In his book, Oberth describes space ships which will run on electricity derived from the Sun, asteroid observatories and special problems which can be expected on a trip through space.

In addition to a detailed description of a moon car, Oberth also includes instructions on how to drive: "The more experience the driver has had on the Earth, the more difficult he will find it to get used to the novel conditions on the Moon . . . On no account should the car just forge ahead and jump at random . . . a stop will be made first, and then a few vertical jumps to reconnoiter the position."

The chapter on space fashions is complete with diagrams. One robot-looking design includes: Front and side windows, containers for compressed air, oxygen and "fuel for the reaction pistol," glove and claw, gripping magnets, short-wave aerial, rear view mirror, hooks and bolts for hanging up suit, heat dissipator, jack for telephone lead, breastplate hinges.

Oberth comments: "The fascinating film star would have his charm very considerably reduced if he wore one of them under actual space conditions."

The why of this book is explained in Wilhelm Meyer-Cords' introduction: "We are on the eve of events to which more fantastic imaginings have been applied than to the majority of progressive mankind's plans and ideas . . . mothers will have every right to know what their sons can expect in their flights through space and wives to be told what dangers their husbands will encounter on their space journeys."

One interesting proposal described by Oberth is a space mirror 27,000 square miles wide which could result in "whole space fleets wiped out," through concentrating the heat of the sun on them. Peacetime projects on which the mirror could concentrate include lighting up entire towns at night, melting icebergs, influencing climate and weather, including the control of cyclones.

Oberth estimates the cost of a space mirror at $3 billion—"less than the cost of a small war." He suggests, however, that this project be held up until his electric space ship is ready to go into service so that material for the mirror could be brought in from asteroids or the moon as "this would be cheaper."

The professor believes that many of his ideas will be put to use by 2000.

NEW from EEMCO

A 400 Cycle AC Linear Actuator with an operating range of 320 to 480 cycles

SPECIFICATIONS FOR TYPE D-818

Normal operating load: 6000 pounds
Maximum operating load: 12,000 pounds
Ultimate static load: 24,000 pounds
Stroke: 3.15 inches
Rate of travel: .33 inches per second
Amperes: 3 amps. at 480 cycles on 200 volts at the 6000 lb. load
Weight: 20.5 pounds
Qualification: Type D-818 has been designed and qualified to meet applicable military and aircraft manufacturers' specifications.

EEMCO 400 cycle linear actuator **Type D-818** is being installed as a leading edge flap actuator in the latest and fastest supersonic fighter aircraft now being produced for the U. S. Air Force.

Incorporated in the **EEMCO** motor in **Type D-818** is a torque-limiting AC clutch which disconnects the high inertial load imposed by the motor's armature. A brake can be built into this mechanism if **Type D-818** is altered for use in another capacity. Adjustable non-jamming stops are included which are especially convenient when the airplane is being rigged.

One of its outstanding features is that it operates on a frequency range of 320 to 480 cycles, versus a normal range of 380 to 420 cycles. This eliminates need for a constant speed drive for the airplane's generator system, thereby saving maintenance of same as well as considerable cost and weight.

EEMCO is a specialist in the design and production of precision-built actuators and motors. The majority of the latest and fastest aircraft and missiles being produced for the U. S. Department of Defense carry one or more **EEMCO** systems. Industry, too, is using **EEMCO** linear and rotary actuators where precise control of mechanical actuating systems is imperative.

Titan Now Our Number One Missile

More Advanced Than *Atlas*
Titan Testing Is Underway

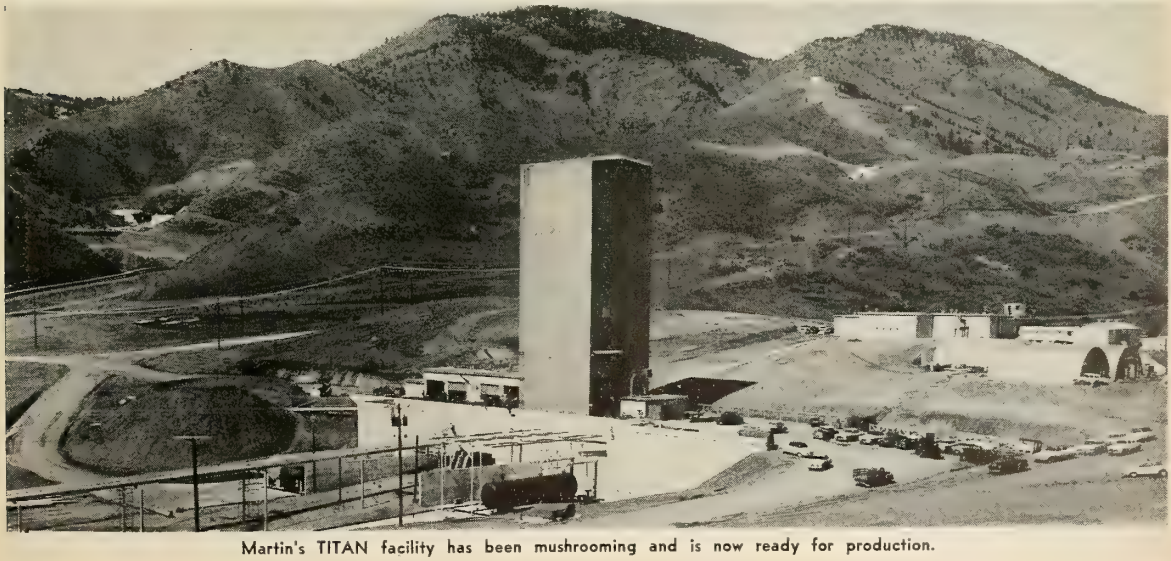
By Erik Bergaust

DENVER—High Air Force officials have revealed to m/r that the TITAN Intercontinental Ballistic Missile effort is in a far more advanced stage than was expected less than a year ago, and that the Martin super missile actually will be a "better" weapon than the ATLAS. Furthermore, Defense Secretary Charles E. Wilson recently referred to "another" intercontinental missile as being more promising than the ATLAS. Obviously, he was referring to the TITAN. It has also been revealed that the TITAN will be more advanced designwise, and that the component test program for this second ICBM is well underway. Aerojet's president Dan Kimball has confirmed that his company is well ahead in development of the 300,000 pound thrust first-stage and 60,000 pound thrust second-stage engines.

A visit to Martin's enormous facility here reveals that the company has exceeded all expectations in getting the *Titan* program underway. Four engine test stands are almost completed, airframe manufacturing is in full swing.

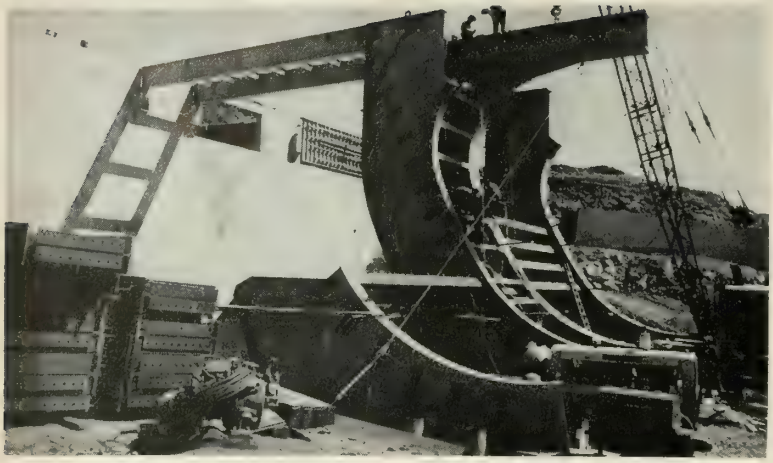
Sure, Martin officials can't even talk about their missile, but it has been known for some time that the *Titan* nose cone project is as far advanced as that of the *Atlas*.

The initial USAF *Titan* development contract, totaling $358 million, has reshaped the geographic organization of the Martin Co. The *Titan* program, centered in the new $10 million facility here, is already in its manufacturing stage.



As a result, a $2 million plant expansion is in the mill. Present employment of 2,500 is expected to reach 5,000 next year. Company officials say building of a landing strip is planned to expedite delivery of parts and for transporting military and civilian people to the site.

In *Titan* guidance, American Bosch Arma Corp. of Garden City, N. Y., is spearheading inertial guidance development and Bell Telephone Laboratories/Western Electric Co. at Whippany, N.J. is working on radio guidance.



Titan is a two-stage weapon with the sustainer rocket mounted directly over the booster. General indications are that the length of the missile mounted and ready to fire is approximately 100 feet with the diameter of the booster maybe 10 feet; that of the warhead and final stage, 6-to-8 feet. Fueled weight is undoubtedly well over 100,000 pounds.

The *Titan* program now is broken down into eight departmentalized functions which perform specialized responsibilities in successfully completing the project. Several of these are well underway.

The propulsion section, which has the responsibility for the engine installation, its propellant feed system and its satisfactory marriage to the airframe, is working closely with Aerojet, planning first engine tests at the

Martin's TITAN facility has been mushrooming and is now ready for production.

Soon to be completed, this test stand at th Denver plant of Martin will be used for early static testing of the TITAN.

Denver site.

The airframe section has the responsibility for the design of the structure, the orientation of the various systems within the structure and the general configuration of the missile. This work is in the mill.

tegration of guidance within the entire system. Little is known of guidance progress, but it must be assumed that it is as advanced as the *Atlas* guidance.

The ground support and equipment section, which has the responsibility of supplying all of the neces-

A total of four static test stands are being built—all expected to be operational this year.

The guidance and control section has the responsibility for the analysis, design, development and installation of all of the control equipment which will help the vehicle maintain a stable flight attitude at all times and the in-

sary equipment required to launch the vehicle, is well ahead in its overall planning. In all, the *Titan* program is well advanced, and, needless to say, Air Force officials are pleased with the progress.

This is a 28,000-gallon, stainless steel "thermos bottle" type tank which will be used for liquid oxygen and other fuels. The tank is 11 feet 6 inches in diameter, and 75 feet in length.

Army Successfully Fires *Jupiter* 1,500 Miles

After two failures earlier this year, the Army recently succeeded in firing a *Jupiter* mid-range ballistic missile to the limit of its designed range, or approximately 1,500 miles. The instrumented vehicle attained an altitude of approximately 250 to 300 miles.

The *Jupiter* carried instrumentation in place of the warhead it would normally carry in operational use. It was controlled by a pre-programmed auto-pilot which held its attitude during flight to the programmed course. Later vehicles will be equipped with a full-fledged guidance system which will include computing as well as sensing elements.

Reds Propose Freight Rockets

Russia's official Defense Ministry newspaper *Red Star* has predicted that "in the near future" missiles may be used to transport troops and supplies.

"It should be noted," said the Soviet military organ, "that plans for using ballistic rocket missiles to move troops and materiel are actually not as far from reality as it might seem at first glance. Delivery of ammunition and certain kinds of arms can already be accomplished by some types of suitably-modified military rockets. . . .

"The question arises, what would be the cost of delivering supplies to troops by means of guided missiles? Undoubtedly such a supply system would not be cheap. However, the advantages which this method present justify the cost. Besides high speed and reliability in delivering materiel, use of guided missiles can significantly lower the cost of supplying troops by ordinary methods. These missiles would reduce the amount of rear echelon transport facilities. . . .

W. R. Grace Produces Purified Thorium

W. R. Grace & Co. will build a plant at Erwin, Tenn., to produce purified uranium, thorium, and rare earth alloys and metals.

Thorium is expected to find extensive use in magnesium alloys for jet aircraft and missiles. First production is tentatively planned for late this year.

Propellant Payoff Found in Systems Contracts

FRENCH LICK, Ind.—The missile and rocket industry gulps down huge quantities of chemicals and looks with hungry eyes toward compounds not yet synthesized.

Just what these chemicals are and what quantities are involved is a puzzler for most chemical people. An attempt was made to supply answers at a seminar here on May 13 and 14.

The program was put on by the Commercial Chemical Development Assn. in cooperation with the Assistant Secretary of Defense (Research and Engineering). Some 180 chemical people—product developers, market analysts, plant managers, and door-beating salesmen—assembled to hear the theme: "What the Rocket and Missile Program Means to the Chemical Industry." Panelists gave a run-down on various phases of liquid and solid rocket propellants and new exotic fuels.

J. J. O'Connell, Program Chairman stated that the chemical industry would like to know what chemicals will be needed for the next ten years. Emphasis was placed on propulsion. Although attendees generally were left with the impression that the chemical market for missiles is big, it was agreed the exact status is difficult if not impossible to evaluate.

Big factors in this nebulous situation are military security, trade-secret tendencies, and systems engineering. Industry spy systems have been able to cope with their competitors' trade-secrets but security and more important, systems planning have floored many a qualified chemical firm attempting to sell products in the missile field. The answer: get in on the ground floor when a system is planned.

Systems the Key

To really cash in, then, the chemical industry will have to adopt the systems attitude. This concept was advanced early in the program in a paper given by Stewart A. Johnston of Ramo-Wooldridge Corp. In addition to the usual propellant logistics criteria, two of the biggest propellant criteria are the need for high density and high specific impulse. The optimum, according to R-W, would be to manufacture all propellants right on base. Presumably this idea will be utilized in building LOX plants right on an ICBM base.

An idea of how much new chemicals might be utilized in a new propulsion evaluation program was given by Dr. John F. Gall of Pennsalt Chemicals Corp. Property testing requires but a few pounds of materials but advances to several hundred pounds while still in the laboratory stage. Static engine tests of a few thousand pounds of thrust might require 400 pounds of propellant per second with a total consumption of 2-4 tons. Thus, consumption in a more advanced test phase would soar to several hundred tons per month.

After this, during peace time conditions, the use might sag considerably. Requirements would only be for replacement, training, and minor development programs. And unless, other uses could be found this would represent a bad product growth curve which might seriously deter the chemical firm from starting in the first place. Dr. Gall, in making his pitch for fluorine propellants, stated that present production is equal to 10,000 tons per month of elemental fluorine and that even a large program would not tax the available fluorine capacity.

Managing Molecules

In an unusually detailed analysis, Rocketdyne's Research Chief, John F. Tormey stated that F-O-N-C-H chemical systems would form the basis of liquid propellants for at least ten years and that during this span we might expect specific impulse to be jacked up by about 50% over present systems.

Future oxidant systems will take advantage of more fluorine and will have increased stability and increased boiling points. Mr. Tormey was confident that materials progress would keep up with the hotter combinations. Though lithium, boron, or beryllium might play greater roles in propellants, Tormey was not so optimistic about aluminum or magnesium compounds.

The storage life of the *Nike I* is now five to ten years even though the system is obsolete. Richard B. Canright, of Douglas Aircraft stated that the booster was a multi-perforated double base solid developed by Allegany Ballistics Laboratory. The sustainer uses UDMH/JP-4 (dubbed M-3 fuel) and IRFNA. Temperature storage limits are now —50°F to 140°F.

A great deal of interest was generated when E. A. Weilmuenster of Olin Mathieson presented his run-down on Project Zip. Based on early German and British work, OM embarked on its boron program in 1952 for BuAer. Of particular interest were the boron hydrides which gave combustion heats of 28,000-32,000 BTU/lb.

Declining to say just what compounds were now being manufactured, it was stated that there was "lots of interest" in the liquid pentaborane. The high energy fuels are not spontaneously ignited in air, and have flame speeds comparable to JP-4. HEF systems are in the works for several missile and aircraft systems. With development, HEF might be used in the B-58 system. OM also thinks that there are commercial applications for Zip.

The liquid portion of the program was terminated by Robertson Younquist who described engine developer's applications and needs from his Reaction Motors viewpoint.

Solids Growing

With some 1-5% of a production missile's cost, the propellant is but a small item said H. W. Ritchey of Thiokol. However, using the Thiokol-made polysulfides in solid propellants has paid off for the firm since some 50-75% of income is from rockets. Thus small chemical firms such as Thiokol, imbued with the systems concept, can profit from a low-volume, high-cost item.

No Upper Size Limit

Lyman G. Bonner emphasized that solid propellants are the most mature of rocket systems and that Allegany Ballistics Laboratory operated by the Hercules Powder Co. was called on early to supply double-base propellants. World War I techniques were the only ones available at the start of World War II. However, double-base solids can now be cast and performance is edging up toward the limit of about 250 Isp. Bonner said that the upper limit of grain size has not yet been reached.

According to Rohm & Haas Co.'s Redstone Research Div. General Manager, Allen R. Deschere, development of solid propellants differs from other chemical products mainly in the rather dangerous nature of the materials being handled. R&H is content with operating a research lab at Redstone and has no plans for getting into the missile business.

How to Get In

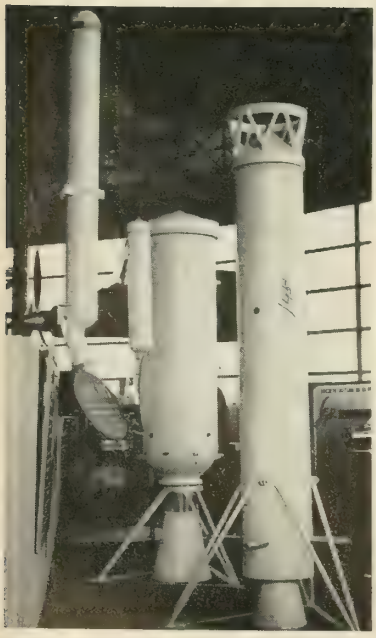
Although the amount of chemicals used in missiles may not be huge, it could be significant for newer materials and for smaller firms. The big payoff is seen to be for those who get in on a systems basis. The road for the chemical industry is clear: get cleared, get out and find out what is needed and start to make it.

Missiles Highlight Paris Air Show

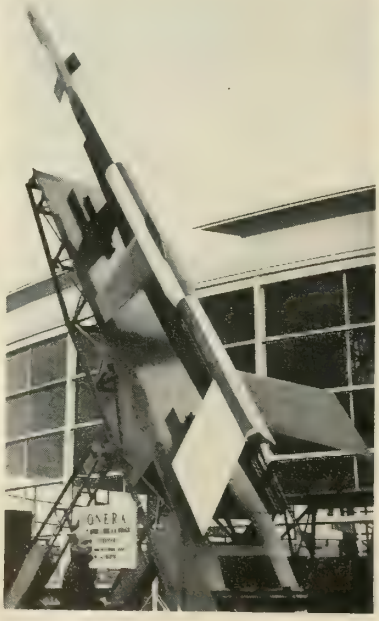
U.S., Britain and France Show the Most Security Keeps Best from View

By Anthony Vandyk and Jean-Marie Riche

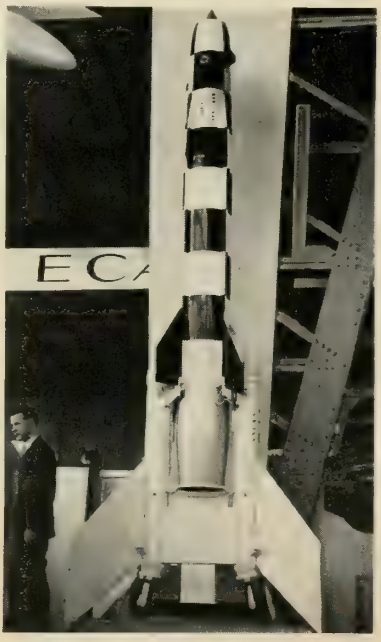
PARIS—U.S., British and French missiles were prominently featured at the International Air Show here. Ranging from the Northrop *Snark* and Martin *Matador* to the smallest experimental rockets, the missiles were the main talking point of visitors. It was clear the European aircraft industry has suddenly become missile-minded.



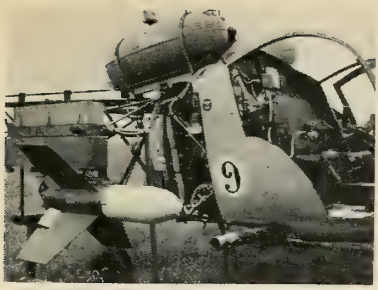
No major manufacturer represented at the show was without some sort of missile exhibit or project. Nonetheless, security prevented any of the latest European missiles from being shown but there were plenty of older models on the British and French stands. Most of them appeared to be subsonic or transonic.



The Bristol *Bobbin* test vehicle made its first public appearance at the show. The Australian *Jindivik* was shown by Fairey Aviation together with its *Fireflash*.



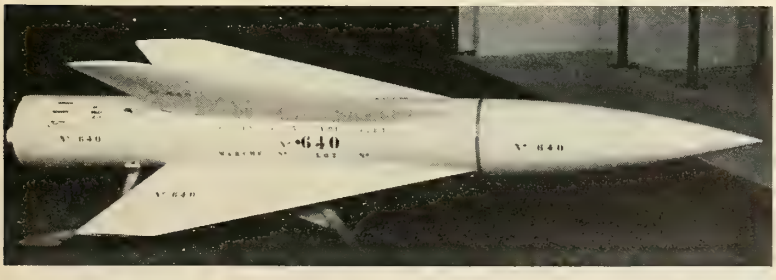
The de Havilland and English Electric/Napier stands held many missile exhibits.



The French, like the British, mainly showed test vehicles. SNCA du

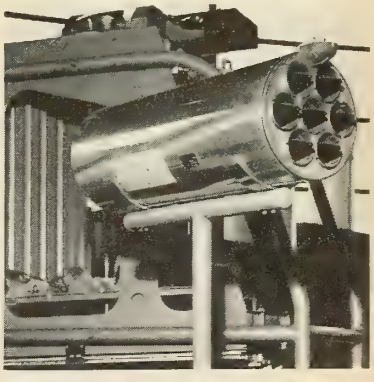
Demonstrating that the French have not exactly been lacking in missile development, this array gives some idea of the different lines of approach being taken by the French aircraft industry. To the left is the Matra 510 air-to-air missile. At the lower left is a selection of solid propellant rocket engines manufactured by S.E.P.R. (Societe d'Etude de las Propulsion Par Reaction). Below center, an experimental two stage test vehicle built by ONERA. Below right is the experimental ST 450 missile (SNCA du Nord) for ramjet testing. A ground-to-air missile has been developed from this vehicle. SNCA du Nord is also working on a ramjet.

This series of pictures shows the French anti-tank missile SS 10, from which the U.S. Army DART was derived. Simplicity and versitility is a feature of the French missile. Both the SS 10 and SS 11 (not shown) are wire guided. Speed of the SS 10 is 328 feet per second; of the SS 11, 655/820 feet per second. Ranges are 1.25 and 1.85 miles respectively. The SS 11 is stabilized in flight by a jet deviator.



Nord was permitted to display its CT-10 and CT-20 drones and to present full data on them which will be reproduced in a future issue of m/r. Nord's SS10's highly successful SSMs were also displayed. Matra's production AAM was slung under a Dassault *Mirage* interceptor.

During the show it was disclosed that France's Bronzavia has licensed its missile ram-air turbine to General Electric for U.S. production. SEPR showed a large number of rocket motors including the model 734 which develops 57,700 lbs. of thrust for four seconds. SNCA du Nord showed evidence of important work on ramjets.



A significant presentation was made by SNECMA of its *"Flying Atar"* VTOL—a piloted jet engine with no wings or other control surfaces. The controllability of this device appeared to be excellent.

It was difficult to obtain specific information on what new missiles are being developed by the French industry. It is known, however, that the French government wants a French atomic ICBM to be ready by 1965 at the latest and for effective SAMs to be in service much earlier.

Improved AAMs are already on the way. In fact, all indications are that the French missile industry is making excellent progress.

To the upper left is the Nord 5.103 air-to-air missile now in production for use on super-MYSTERE day fighters and VAUTOUR all-weather fighters. Carrying a warhead of 57 pounds of TNT the missile has a range of 6.2 miles and a speed of 1640 feet per second. It's either a beam rider or radio guided. Lower left is the CT 20 target drone which have been used by French forces and exported to Britain and Sweden. Above is a MATRA rocket launcher.

Bourns NEW TRIMPOT JR.®

- micro-miniature size
- high power rating
- humidity proof

*Trade Mark

This micro-miniature potentiometer is designed for use with printed circuit boards and modular-type assemblies, and is derived from Bourns' original TRIMPOT.® The new TRIMPOT JR. is only 3/16"x 5/16"x 1" in size. Seventeen units can be mounted in one square inch of panel space. Power rating is 2 watts, and maximum operating temperature is 175°C.

The TRIMPOT JR. is built to meet or exceed government specifications for humidity, salt spray, vibration, acceleration, and shock. This potentiometer features a 15-turn screwdriver adjustment and 1½", 0.016" diameter leads. The shaft-clutch assembly idles when the mechanical limits are reached, thus preventing possible damage from forcing of adjustments. The TRIMPOT JR. is mounted with 2-56 screws through stainless steel eyelets on ¾" centers.

New Propellants Insensitive To Shock

A new solid propellant, a replacement for black powder and diglycol propellants, was described by Dr. G. von Francois, formerly a special Speer Ministry employee. No. 36E, dubbed yellow powder, consists of 53.5% tetranitro carbazole, 42.5% potassium nitrate as oxidant, 2% carbon, 3% wood flour and 4% polyvinyl acetate as binder. The cool-burning propellant can be used over a temperature range of —58° F to 140° F. Not sensitive to shock, the plasticized mixture burns to give a slightly yellow smoke exhaust.

German solid propellants formerly based on black powder or diglycol dinitrate now appear to be shifting to the high energy composites. Also, the production of synthetic glycerine by one of the Farben groups will now give capacity for production of nitroglycerine-type double base solids. Another propellant combination is based on tetranitro diphenyl amino sulfone. Several German labs are doing research on new organic solid monopropellants: nitro, nitrate, or nitroso compounds.

French SEPR Builds Two Big Boosters

The French SEPR group has successfully scaled up solid propellant rockets and have come up with two new boosters:

	SEPR 73	SEPR 5052
Thrust, lb	55,000	29,700
Burning Time, sec	4	4
Chamber Pressure, psi	1,030	1,030
Propellant Weight, lb	940	620
Total Weight, lb	1,625	1,030
Total Length, in	106	105
Diameter, in	25	18

Propellant type is not known.

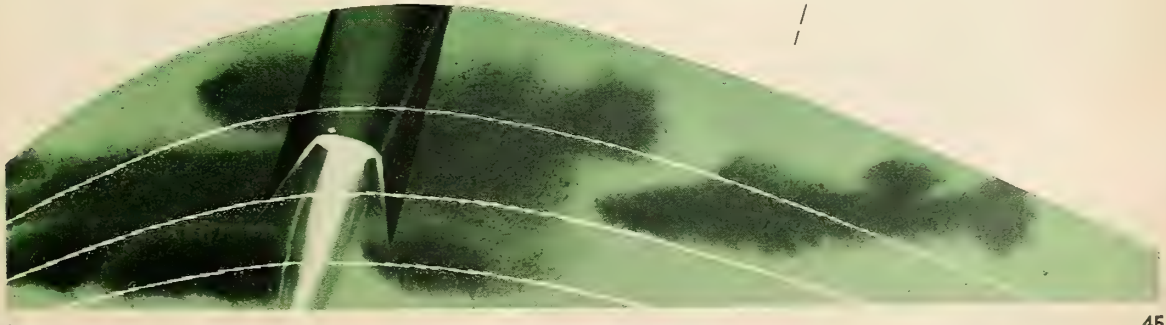
Longer Satellite Lifetimes Predicted

At the recent American Astronomical Society meeting in Cambridge, Theodore E. Sterne postulated that the *Vanguard* orbit may result in a satellite decay period of 8-10 years based upon latest Air Force Cambridge Research Center atmospheric model. If this turns out to be so, subsequent satellites will be launched at lower altitudes or lower speeds to obtain upper atmosphere density checks within a shorter interval.

Now! Cool through the thermal barrier with FLAMEMASTIC!

The high-heat insulating *material proved* in *actual production* for *4 years*

Now, you can provide positive protection and high-heat insulation for metal surfaces with FLAMEMASTIC. For four full years, FLAMEMASTIC has been used exclusively on one of the major production missiles. And it has been applied extensively in other experimental firings of rockets and missiles and on allied test and launching equipment.



FLAMEMASTIC protects against high-velocity combustion heats, ranging from 3000°F. upward. This insulation provides positive protection for vital electronic equipment.

FLAMEMASTIC is readily applied by conventional application methods.

Missile Program Sharply Criticised by Congress

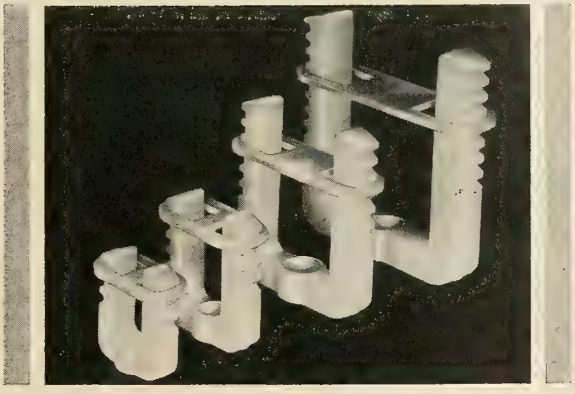
The House Appropriations Committee subtracted $2,586,775,000 from the military appropriation request for the fiscal year beginning July 1, but insisted the cut will not jeopardize U.S. military striking power.

The lawmakers reported out a bill recommending $33,541,225,000 in new obligational authority for the Defense Department in fiscal 1958, compared with the $36,128,000,000 originally requested by the Administration and the $34,698,523,000 actually voted for the current year.

In support of its cut, the Committee said that the Soviet military threat to the U.S. and its allies appears to have "somewhat abated," but it acknowledged that the Soviet Union is closing the gap in military power.

"In the field of missiles we are in a nip and tuck race with Russia. We are no doubt ahead of the Soviets in the field of guided missiles generally. In the ballistic field, we are probably behind the Soviet Union in progress made in the perfection of the Intermediate Range Ballistic Missile. In the Intercontinental Ballistic Missile area, we are very probably ahead of the Soviets," the Committee said.

The House group had some harsh words in its report for what it called the "apparent lack of timely, effective and decisive action on the part of the Office of the Secretary of Defense in achieving a well-rounded, coordinated guided missile program at minimum cost commensurate with an adequate system." (See Industry Spotlight, p. 169). The Committee strongly urged more prompt and effective evaluation of competing military missile projects, particularly for the non-ballistic missile area.



The congressmen agreed that a certain amount of duplication is necessary in the ballistic missile projects, but added: "It is hoped that within the next few months the ballistic missile program will become clarified and the maximum of lost motion eliminated."

Except in the case of the Air Force, the precise impact of the Committee's action on the missile program was not disclosed. The USAF's $1,414,800,000 request for missile procurement ($676,900,000 for ballistics and $737,900,000 for non-ballistics) was trimmed $70,000,000 "as a reflection of the Committee's dissatisfaction with Air Force efforts in this area," but it was stated that none of the reduction is to be applied to the ballistic projects. Another $5,000,000 was lopped from the Air Force's $105,700,000 request for missile spares to take account of the cut in missile procurement money.

The Committee also gave the airmen a tip on cetrain missiles they might do well to abandon. It said some of the 18 separate missile development and production projects now carried on by the Air Force are of "doubtful value" and it included the Bell *Rascal* air-to-surface missile in this category, noting that the Defense Department feels it is a "marginal" weapon.

A $12,000,000 cut was recommended in the USAF request for $661,000,000 in new research and development funds, but this was not allocated among specific projects. The Committee said this reduction was ordered to emphasize that all possible economies should be effected, particularly in scientific and engineering manpower.

The Army's $583,000,000 procure-

new Zytel wire clamp cuts weight in planes and missiles

This unique wiring clamp weighs only 0.001 lbs. for 3/16" capacity handling 58,000 circular mils . . . only 0.052 lbs. for 2-1/2" capacity handling 8,570,000 mils. It resists fatigue in any position, and withstands loadings up to 50 g's. Easy installation—place wire bundle between U-shaped horns; push down the keeper—it locks, with permanent holding power. Sizes range from 3/16" to 2-1/2" across the horns.

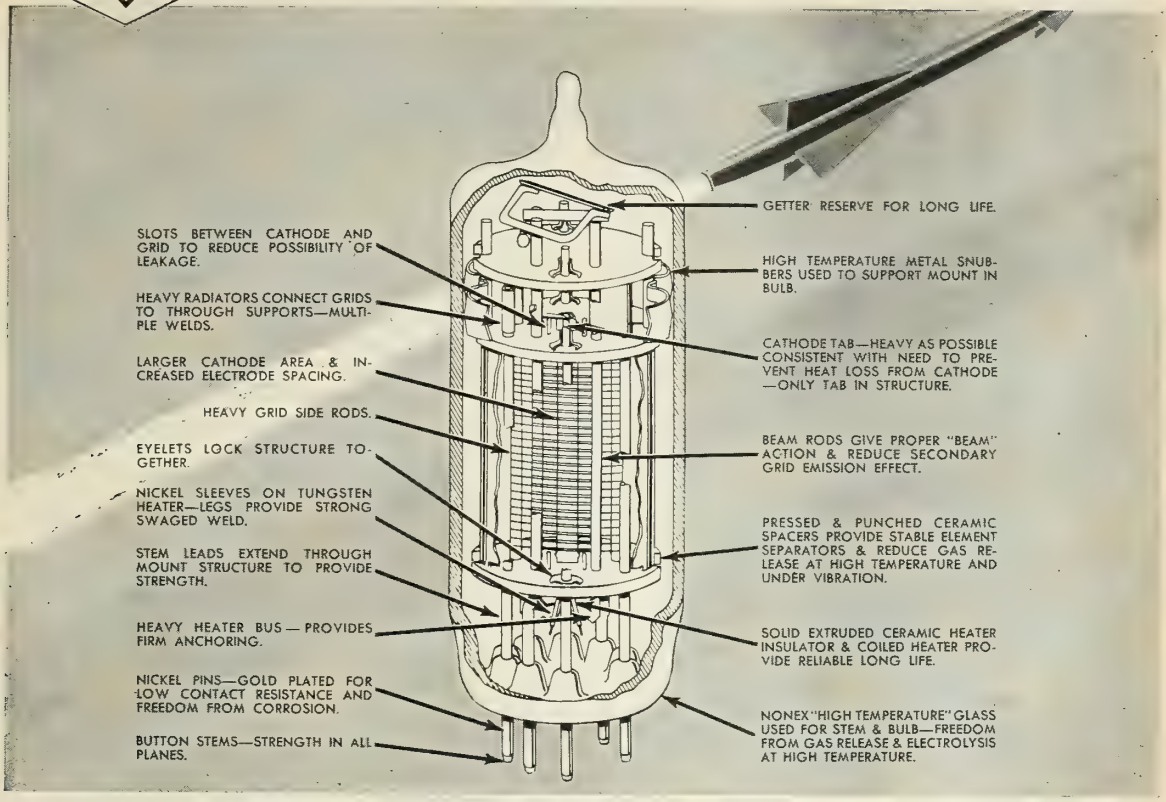
ment request for hardware, including missiles, was reduced by $516,000,000—the amount of the total request the soldiers expect to carry over into fiscal 1959 unobligated. The Committee acknowledged that the reduced amount will give the Army less latitude than it wants, but said the amount should prove adequate if improvements continue in management and planning operations. A cut of $8,000,000 was also ordered in the Army's $400,000,000 R&D request.

The Navy buys missiles in two separate accounts—aircraft and related procurement administered by the Bureau of Aeronautics and ordnance and ammunition, handled by the Bureau of Ordnance. BuAer's request for aircraft, missiles, drones and related items was cut $120,000,000 to $1,812,000,000, but the Committee expressed confidence that the Navy can carry its program with the lesser amount since experience has shown that considerable savings through program changes, contract repricing and the like may be expected.



BuOrd's $256,000,000 request for ammunition and missile money (including *Polaris*) was reduced to $176,000,000, on the strength of BuOrd's past poor performance in hitting its obligation targets, anticipated reimbursements from the military assistance program and the volume of carry-over funds available. The Navy's total R&D request of $505,000,000 was also cut by $10,000,000.

Soviet Research Poorly Organized

Professor Peter L. Kapitsa, the celebrated Soviet physicist, in an article published in the Moscow *Pravda* last month complained of the poor organization of certain important research projects in the Soviet Union today. Giving the construction of an atomic-powered airplane as an example, Doctor Kapitsa pointed out that one Soviet scientific agency usually takes over the entire project, then farms out certain parts of it to various other agencies, whereas a better approach would be for only one team to be responsible, without farming out even the project's smallest parts.

He listed agencies and specialists in atomic energy, thermotechnical problems, and aerodynamics among those now involved in the building of the Soviet atom-powered plane. He hinted in his article that some of these agencies and experts do not work with others in entire harmony. Better team work, through greater centralization, is necessary, declared Dr. Kapitsa.

HY-G-300 **ELECTRON TUBES FOR SURVIVAL**

WHY BENDIX* HY-G-300 ELECTRON TUBES ARE BEST FOR EXTREME SHOCK, VIBRATION AND TEMPERATURES!

From the standpoint of design features (see above), these reliable hard glass tubes offer the superior quality needed to survive today's severe environmental demands.

Specifically, Bendix HY-G-300's are designed to withstand the following environmental conditions—bulb temperatures up to 300° C; vibration up to 20G's over the range of 5-2000 cycles; and shock of 200G's having 20-millisecond duration.

Launched toward the Future in WEAPON SYSTEMS MANAGEMENT

Rascal—GAM-63 air-to-surface missile of the USAF—is an operational example of complete weapon systems management by Bell Aircraft. As prime contractor, Bell's responsibilities embraced the design, development, and production of the entire system including airframe, guidance, rocket engine, servo-mechanical devices, launching and ground support equipment as well as flight testing and training.

The personnel responsible for this successful program has recently been regrouped to form a new *Guided Missiles Division.* Its sole function is to provide complete and coordinated management and production for any weapon systems program.

The men who make up this division ar a skilled and diversified team of specialists with a total of some 100,000 man-years of experience in guided missiles. Prior to "Rascal", they were responsible for Tarzan, Shrike and Meteor. Current responsibilitie also include important components for the Niké, Hustler, Regulus, Navaho and various I. C. B. M. and I. R. B. M. programs.

These men have past success to attest to their capabilities and foretell future accom plishments. They will be heard from again and again for important achievements in the years ahead.

Russians Report Super Peroxide

A member of the D. I. Mendelev Institute of Chemical Technology in Moscow, A. P. Purmal, suggests the existence of a super hydrogen peroxide—H_2O_4. Reporting in the *USSR Journal of Physics,* the scientist told of irradiating a fresh hydrogen peroxide solution with a mercury arc light to drive off all oxygen. Oxygen evolved is measured and the solution titrated with potassium permanganate.

Titration results were shown to be lower than calculated. The gas evolved gives the bonded oxygen while titration gives the hydrogen combined with peroxide oxygen. The scientist states that the two methods agree when no other peroxide forms are possible. Purmal, in typical scientific fashion, however, wants other confirming proof.

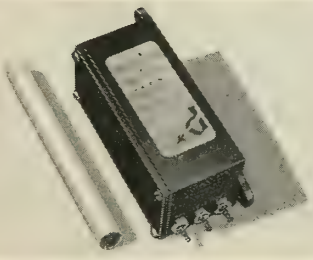
If super peroxide could be prepared, it would be very useful as a replacement for normal peroxide. Although containing some 97% oxygen (hydrogen peroxide has 94%), it could yield twice as much *available* oxygen. Other desirable properties hypothesized: higher density, ease in catalytic decomposition, high boiling point and low freezing point. The next step, perhaps already in the mill, would be isolation and study.

Controversial Clue Sparks Symposium

Over-instrumentation was one of the most controversial subjects discussed at an informal missile forum held during the Instrument Society of America's 3rd National Flight Test Symposium in Los Angeles, Calif.

All participants agreed, however, there was too great a variation in the nature of tests to establish an arbitrary line between too much and too little.

It was emphasized that all firing tests of complete missiles should be made on an "inter system" basis by placing a boundary or engineering parameter around each system and measuring only such actions as take place between systems. This theory assumes that component accuracy is within specified tolerances and that each component of each system has been thoroughly checked prior to the test of each system.

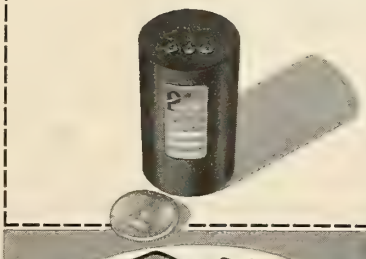


The use of system boundary techniques would limit the amount of monitor channels to about 140-150 rather than the several hundred required when system components are

ONE OF THESE 4 PACIFIC
Accelerometers
CAN PROVIDE RELIABLE ACCELERATION MEASUREMENT FOR YOUR OWN NEEDS!

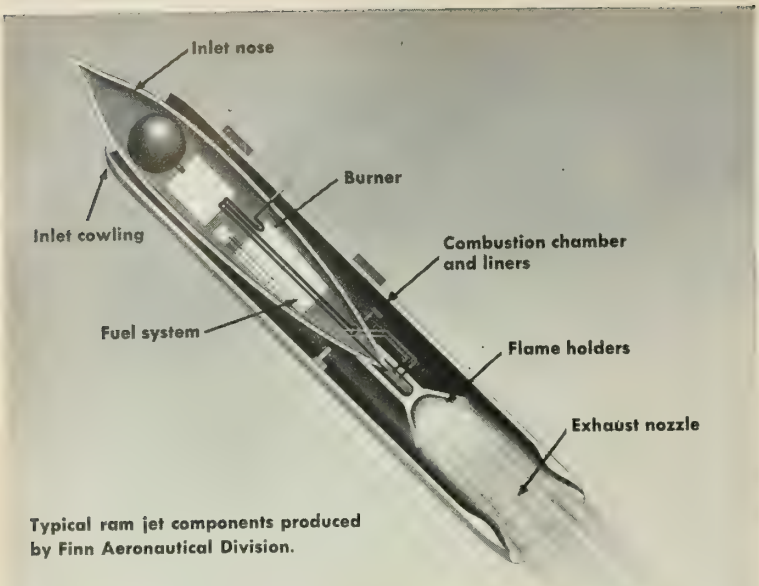
Four basic Pacific Accelerometer types — already designed and developed — can be used to meet practically any acceleration measurement requirement! Send for complete data sheets!

HIGH ACCURACY POT
Single or dual potentiometer pick-off and/or switches . . . automatic caging mechanism. A unique torsion-bar suspension and restraining system provides very low hysteresis with exceptionally rugged, long life. Available in a wide variety of G ranges.
SERIES 4202



LIGHTWEIGHT, MINIATURE
accelerometer combines a wide flexibility of design and performance characteristics with a proven, high production instrument. Potentiometer pick-off... wide selection of G ranges with an operating range of 0—±1 G to 0—±50 G.
SERIES 4201

HIGH ACCURACY AC OUTPUT
linear accelerometer designed for high response systems requiring AC signal. This unit provides an accurate, large output AC signal while maintaining a high natural frequency and low cross talk. Temperature compensated fluid damping provides exceptional dynamic characteristics *without* heater.
SERIES 4204



NO CROSS TALK
due to uni-directional design this instrument measures acceleration in one direction only, and cannot produce any output signal from cross accelerations. Pot pick-off . . . available in a choice of many G ranges.
SERIES 4203

measured at the tame time system performance is being evaluated. It was felt that component measurement has no place during a test firing other than sufficient instrumentation to "fingerprint" which components *could* have malfunctioned. This technique, it was stated, was one means of providing maximum information with a minimum effort, resulting in fewer dollars spent.

It was stressed, however, that the amount of instrumentation required for test firing varied with the project's size and complexity. Although an aircraft may have hundreds of hours of flight testing prior to acceptance, a missile must render the bulk of its information in a single flight, and missile engineers need all the information they can get on the performance of any system or component involved. Some concern over inadequte instrumentation during test firings was also expressed.

Pointing out that as new equipment and new installations are made, new instrumentation will be required, a representative of one missile test facility noted that their static test instrumentation was increasing at the rate of approximately 20 per cent per year, but the additional instrumentation tended to reduce the number of tests required.

There was general agreement when several of the panel and members of the informal "workshop" declared the responsibility for the amount of instrumentation should be a decision of the instrumentation engineer after an evaluation of the design engineers' requests.

French Astronomer Speaks at Harvard

The well-known French astronomer, Gérard de Voucouleurs, recently told a Cambridge, Mass. audience why he would like to have a close look at the planets. Speaking at a panel discussion at Harvard University, he excluded all the bodies of the solar system but Venus and Mars for reasons of distance or temperature extremes.

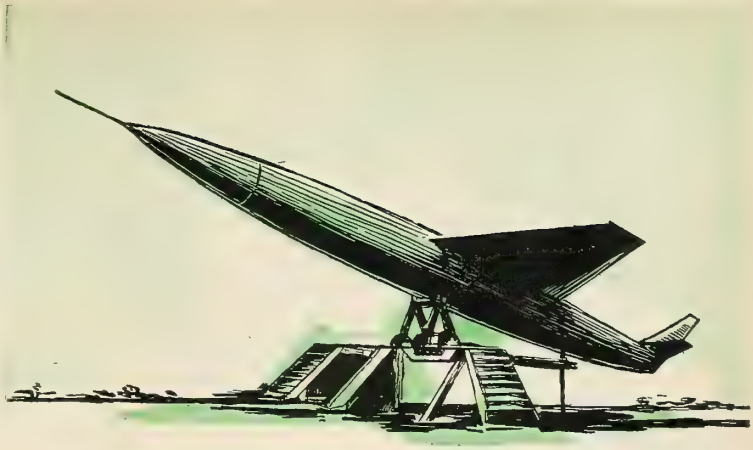
Dr. de Voucouleurs would like to determine the mass of Venus by satellite techniques, a quantity inaccurately known today because of the fact that Venus lacks a natural moon. He suggested that radio-ranging could be employed to find not only the depth of the atmosphere but the diameter of the planet. Observations, he said, could be made either by artificial satellites or some sort of probe.

Mars received the lion's share of the French astronomer's attention. Among the studies that could be made,

Dr. de Voucouleurs discussed the following: oblateness and internal structure and discrepancies between present optical and dynamical determinations, fine structure of surface markings, continuous strip mapping surveys, spectroscopic tests of the atmosphere (carried out either between two vehicles or using one with a reflecting mirror), radio observations for determination of Martian relief, variable frequency sounding for detection of ionized atmospheric layers, possible ring-current investigations and magnetometer surveys. He felt that it may be feasible to shoot rockets into the atmosphere from a satellite to determine wind velocities and directions.

Naval Factory Honors Rocketeer

The Naval Powder Factory at Indian Head, will honor the late Dr. Robert H. Goddard on 25 June 1957 by dedicating its new power plant in his name. It will be the Navy's first high pressure (900 lbs.—825°F), centrally controlled, electric and steam generating plant.



The Naval Powder Factory has supplied the Navy's need for cannon powder since 1900 when the manufacture of smokeless powder was begun.

Today, the powder factory is devoted almost exclusively to the scientific investigation of propellant ingredients, grain design, and experimental production, as well as full scale manufacture, testing, inspection and surveillance of propellants for rockets and guided missiles.

Dr. Goddard conducted rocket research at the powder factory between 1920 and 1922. His efforts were directed toward devising a rocket driven, deck-penetrating bomb.

Tiny Meteorite Detector Developed

Instrumentation for measuring meteoric surface erosion or penetration depth has been developed which weighs only three quarters of an ounce. Developed by Professor S. Fred Singer at the University of Maryland, the device utilizes Sr-90 as the radioactive source in a transistorized circuit. The system is adaptable to operation from either the Minitrack 22 volt supply or, with a different circuit, to 2.5 volts. Current drawn is only 0.1 microamperes. Tests are being run in a shock tube to simulate high speed meteoritic dust particle impacts. The experiment appears suitable for both satellite tests and high altitude sounding rockets.

When it has to be heated rely on Safeway Woven Heat Elements

. . . and the "it" can be just about anything from a simple tray to the curing blankets for honeycomb structures.

Safeway Woven Heat Elements are custom tailored to fit specialized requirements of many applications. A single aircraft, for example, may need upwards of 80 different heating and de-icing elements, all of which are made by Safeway. Other applications are on helicopter rotors, rocket tubes, missile launchers, and on a wide variety of molds, dies, tanks, ovens and dryers in industry.

If you have a problem that requires heat, let Safeway engineers study your requirements and—without obligation to you—submit an appropriate recommendation.

For your copy of a fact-filled folder, write to:

Moscow Claims to be Building an Atomic Plane

They are now building an atomic-powered airplane in Moscow, it has been announced by the Soviet government. The plane will make uninterrupted globe-circling flights at speeds up to 1800 mph. It will also fly nonstop from Moscow to Mirny, the new Soviet base in Antarctica.

"We need regular air communications with Mirny and other Antarctic points," Professor G. Pokrovsky, the chief Soviet authority on atomic planes declared recently.

Despite the fact that the Soviet atom plane is as yet in its first preliminary phase of experimentation, Pokrovsky and his associates have not the slightest doubt that the plane will be a working reality soon. Professor Pokrovsky and his staff admit that there are still unsolved problems but they claim Russian science is confidently on its way to their solution.

Another Moscow physicist-mathematician, Y. Balabanov, elaborates: "The most serious handicap in the utilization of nuclear energy in airplanes is the heavy weight of the protective concrete walls safeguarding passengers from harmful radiation of the reactor. This weight reaches 100 tons.

"Should we succeed in reducing the weight of such walls to 40 tons, such an airplane could lift a cargo of 15 tons and could carry 180 passengers at 1600 kilometers per hour."

Professor Pokrovsky admits that "the problem of relaying heat from the reactor to the motor is also complex." Still, he says, the Soviets can and will make it light and compact. He feels that the entire plane could weigh about 100 tons.

The plane's reactor will have to work at temperatures of more than 1000°C. "What materials are capable of bearing this heat without disintegration or even softening?" asks Pokrovsky. "What materials would successfully resist the furious bombardment by neutrons able to cause complex changes in matter?"

But such materials can be found, the Soviet scientist asserts. On the one hand, science must awaken new and yet newer forces of nature to action.

Atomic power will make the future plane's speeds exceed by far even the top rates of present-day supersonic aircraft. The surface of the plane will become so heated that it will generate tremendous streams of super-hot air around itself. Therefore men must have new, heat-resisting alloys for the plane —different alloys perhaps than those for its reactor. Moscow's scientists are now laboring on this problem too, with every prospect of early success, Dr. Pokrovsky tells us.

Pokrovsky adds that future atomic aircraft will have rotating jet motors which, on the plane's ascent, will assume a vertical position and will thus give the plane vertical takeoff capabilities. "Just like a helicopter."

Balabanov adds:

"Such an atom-driven plane will be able to fly endlessly. With a supply of 1000 kilograms of nuclear fuel, an atomic airplane would have operating power at its disposal equal to about 2 million kilograms of benzine."

This means, continued the Moscow spokesman, that interplanetary flights will in due time, become a possibility. "A rocket to be used for this purpose will have to move in airless space," Balabanov reminds us, "and for its jet-propelled motion a sufficient supply of liquefied gas is necessary."

Rocket Trends

By Erik Bergaust

Missile talk in recent months—for good reasons—has been mostly about intercontinental vehicles. *Navaho* versus *Snark*. *Atlas* versus *Titan*. These missiles will continue to be in the news for years to come because they are important. The long-range missiles have top priority. They should have.

But let us not forget that intercontinental missiles make up only part of the important arsenal that is required for the defense of this country and the rest of the free world. Let us not move along blindfolded, neglecting the other categories. In particular, let us not forget the anti-aircraft and anti-missile missiles. We have heard some terrifying statements about lack of accuracy in *Bomarc* guidance, for example. And what has happened to the *Talos?* Is the *Talos* program bogged down? Last but not least, the latest word on the "incapability" of our *Nike* systems comes from Russia!

Among the publications that our "Russian Editor" scans carefully every month is Sovietskaya Aviatia. This newspaper-type periodical had plenty to say about our *Nike* last month.

It described launching facilities, radar-guidance systems, speed, range and altitude limits of the *Nike* and its installation in conjunction with 90-millimeter antiaircraft artillery.

After reviewing some details, the paper said that the *Nike* missile was very far from modern, because it can hit only single targets.

Sovietskaya Aviatia minimized the value of tests of the *Nike* as reported by the U.S. Army. It said these were conducted against "obsolete piston-engined planes flying at speeds of 200 miles an hour."

"When firing the *Nike* missile under real conditions, where the speed of maneuvering planes keeps changing, the chances of hitting the target become greatly lessened" from the 65 hits out of 100 claimed for the missile, the paper said.

The Russians aren't telling us anything new. Of course, we know the *Nike* is far from perfect. It remains a sad and grim fact, nevertheless, that the Russians are so fully aware of the holes in our air defense system. Certainly it should spur our military leaders to accelerate our advanced anti-aircraft and anti-missile missiles. Obviously, the Russians know that these weapon systems do not exist in this country as yet other than on paper.

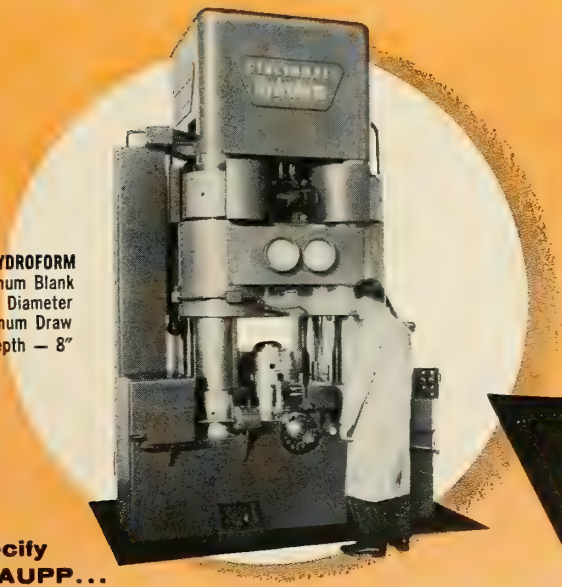
There has been some talk about sky-high expenses and non-feasibility in connection with anti-missile missiles. But the majority of our missile experts say an anti-missile missile can be built. Can we afford not to try?

As far as money is concerned, we have noticed that the airmen have programmed $955.7 million for the ICBM/IRBM program for next fiscal year, while "other missiles" will receive $739.9 million worth of attention. How much money will go for *Bomarcs* has not been disclosed. Nor do we have any figures on how much the Army can and will spend on the *Nike Hercules* and *Zeus*. But since the Army's share of the defense budget is microscopic, it appears very little effort is being put into the life-and-death defense weapon, the anti-missile missile.

The drastic slicing of the defense budget is going to hurt all around, of course. In particular, the missile program will suffer considerably. Certainly, there doesn't seem to be any large sum around for an extensive anti-missile R&D program unless Charlie Wilson can dig it up from his special emergency vault. The worst that could happen would be the need for Congressional sanction for such money. Congress probably wouldn't have time to okay this before it adjourns this summer. And this would mean a dangerous set-back time-wise in the anti-missile program.

Now...a battery of Hydroforms at

Kaupp



8-INCH HYDROFORM
Maximum Blank — 8″ Diameter
Maximum Draw Depth — 5″

— to reduce your development time and costs on every pre-production run!

Kaupp hydroformed prototypes and pre-production parts are accurately formed and drawn in less time, at lower cost. Hydroforming produces short run, and in some cases production pieces, quicker and more economically than tool and die methods. New equipment installed by Kaupp assures faster service. For complete information on Kaupp metal forming facilities, call or write today!

FEWER DRAWING OPERATIONS

Washington Spotlight

By Henry T. Simmons

Booming missile activity is a chief factor in the massive over-run in Defense Department expenditures anticipated for the current fiscal year. The Administration predicted a $36 billion spending total for the Pentagon in January; now it looks like the military will go through at least $38 billion before the close of business on June 30. Almost three-quarters of the $2 billion over-run can be traced to the Air Force hardware accounts. The airmen told Congress they expect to exceed their January estimate by $1.4 billion—half the excess coming in the *Atlas*, *Titan* and *Thor* projects. Pentagon has slammed the brakes on overtime payments to contractors in an effort to bring runaway spending under control, but the vital ballistic projects were specifically exempted.

•

Third test flight of the *Navaho* in April was a complete washout. The big missile's multiple booster engines fired for perhaps two seconds, then cut off in response to a wild signal from within the missile. Source of the trouble is known. Meantime, North American has successfully tested a 400,000-pound liquid-propellant booster for the production version of the *Navaho* (if there is one); it would replace the three units of 120,000 pounds each now used with the XSM-64. The new engine, incidentally, is the largest liquid rocket motor known to exist today.

•

Lockheed's supersonic X-7 ramjet test vehicle has evolved into the Q-5, a recoverable drone now under development by the Air Force. Like its prototype, the Q-5 utilizes a ribbon chute to slow down after burnout and lands on its spike nose without damage to the rest of the vehicle. USAF has worked out a deal with the Army at nearby White Sands which permits the soldiers to blaze away at the Q-5 with *Nikes* during the test flights. Army has promised to crank an offset error into its fire control system to assure a minimum number of actual hits on the speedy drone development vehicles.

•

Apropos of the deliberate destruction of the USAF *Thor* IRBM during its second test flight, a tale now going around puts the blame on a faulty radar instrument used by the range safety officer. According to the story, the IRBM was sticking to its course, but was detonated by the safety officer on the basis of false information reported by his instruments. Two other monitoring systems reportedly showed that the *Thor* stuck to its flight plan during its 38-second trip.

•

The Navy isn't happy about its contractual arrangement with Convair for procurement of the *Terrier* ship-launched anti-aircraft missile, now priced at $64,000 a copy. Rear Adm. Frederic Withington, Chief of the Bureau of Ordnance, told lawmakers he would like to have a more competitive type of contract for the bird, but said this is not possible because of the high cost of bringing in a second source. Grumbled Withington: "I wish that I could get out of Convair's pocket with the *Terrier* missile, but I cannot . . . I do not like it, and I have to accept it."

•

On the other hand, the Navy appears to be quite happy with its *Sidewinder* air-to-air missile, which was developed by the Naval Ordnance Test Station at China Lake, Calif. Cost of the infra-red bird has dropped almost 50% over a three-year period. It cost $4,591 in 1956, $3,998 this year, and its estimated fiscal 1958 cost is $3,540.

To the ENGINEER of high ability

Through the efforts of engineers The Garrett Corporation has become a leader in many outstanding aircraft component and system fields.

Among them are:

air-conditioning

pressurization

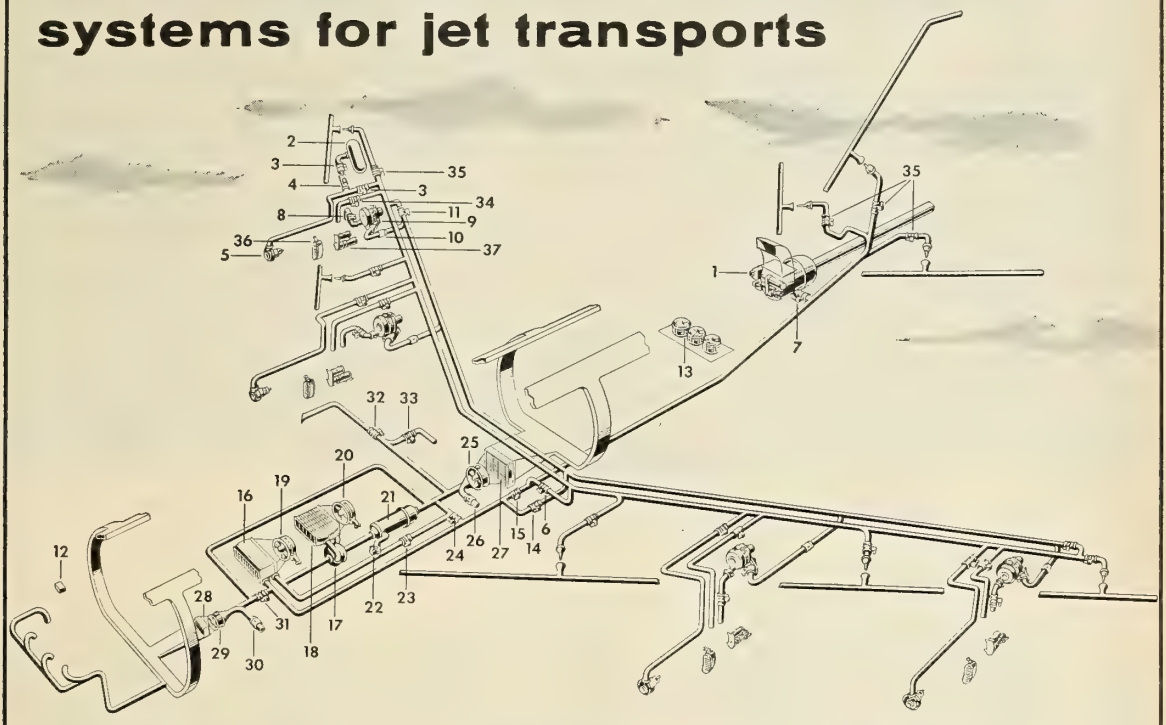
heat transfer

pneumatic valves and controls

electronic computers and controls

turbomachinery

The Garrett Corporation is also applying this engineering skill to the vitally important missile system fields, and has made important advances in prime engine development and in design of turbochargers and other industrial products.



Our engineers work on the very frontiers of present day scientific knowledge. We need your creative talents and offer you the opportunity to progress by making full use of your scientific ability. Positions are now open for aerodynamicists . . . mechanical engineers . . . mathematicians . . . specialists in engineering mechanics . . . electrical engineers . . . electronics engineers. For further information regarding opportunities in the Los Angeles, Phoenix and New York areas, write today, including a resumé of your education and experience. Address Mr. G. D. Bradley

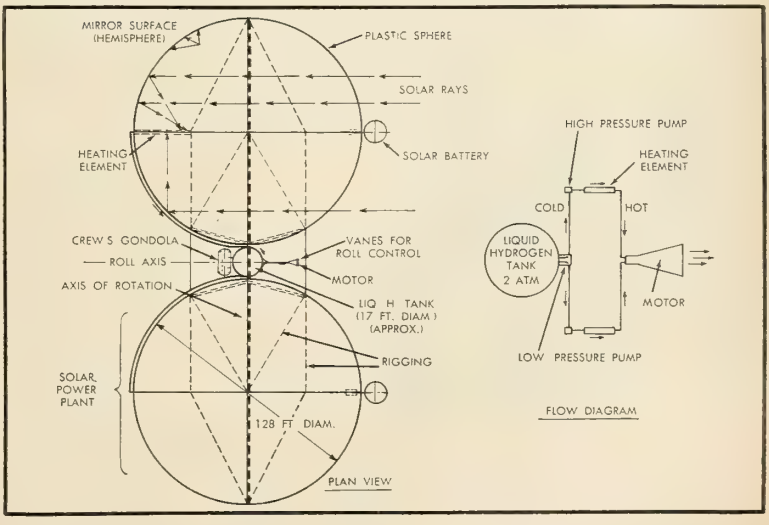
Known Limits on Chemical Propulsion Systems Demand Early Answer to "What Comes Next?"

By Seabrook Hull

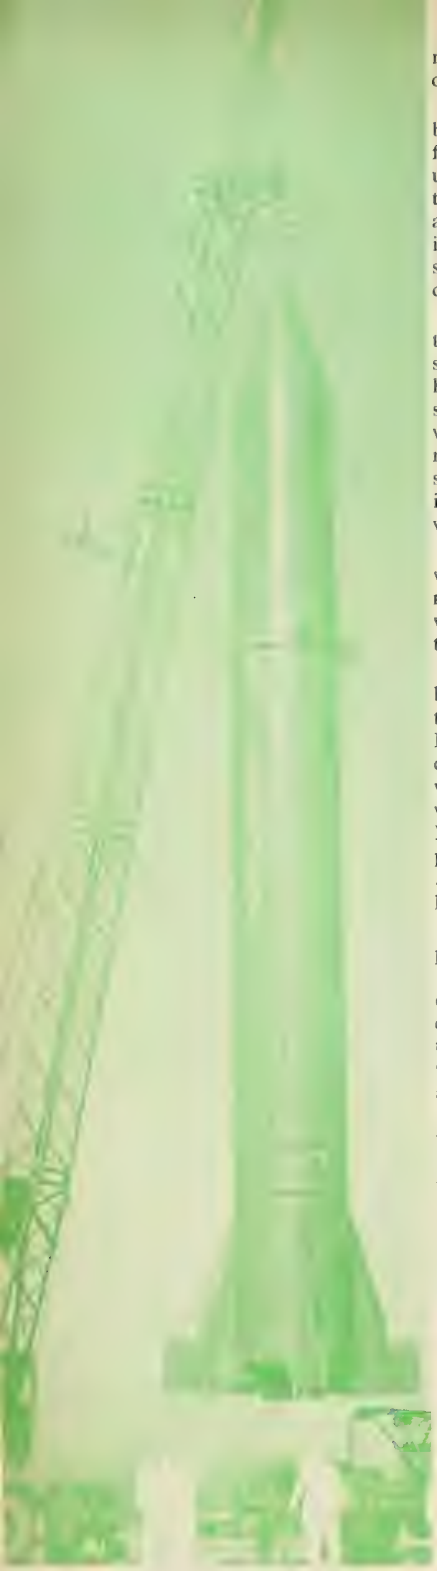
WITHIN LESS TIME than it's comfortable to contemplate—perhaps within a decade—man's demands on flight propulsion systems will exceed the capabilities of any known or imagined purely chemical combination, such as the turbojet, ramjet or rocket. This will be true first of military, later of commercial requirements. It is inevitable not only in the case of practical space flight, but also as flight operations are extended into the upper reaches of the earth's atmosphere.

The military urgency is to maintain air superiority over the Soviet Union. In the absence of specific fact there can be no other assumption than that the Russians are exerting a major effort to transform their long-term interest in astronautics into usable hardware. And who first rules the ionosphere gains an immense advantage over his adversary. In turn, the same is true of outer space.



A major consideration in this connection is a propulsion system that has both flexible power and endurance and that is adaptable to the changing conditions of its environment—that can ease readily from the dense lower atmosphere to the ionosphere to free space and back. It should also be as economical as possible in original construction costs, operation and maintenance.

As detailed elsewhere in this issue of m/r, materials will limit combustion chamber temperatures of chemical propulsion systems to about 3000 degrees Kelvin. No matter how efficient a free radical or "zip" fuel reaction may be in heating and accelerating exhaust gases, if it entails higher temperatures, it cannot be used for flights of more than a relatively short duration. They would have to be based on the gradual destruction of the combustion chamber.



Thus, barring development of a practical means of reconstituting the basic structure of matter so that atoms will take a much stronger grip on other atoms, enabling materials to remain solid to higher temperatures, the absolute theoretical limits of chemical propulsion are known. The very best that can be done, for example with a liquid, solid or jelly propellent rocket is a 40% increase in specific impulse.

For flights about the earth this means a specific and relatively low ceiling on velocity. For travel into outer space it means a prohibitive limit to range and maneuverability. For this reason there is as much urgency as academic interest in determining as soon as possible what comes next.

Among the possibilities are four of purely nuclear propulsion; two electrical systems; one photonic and an as yet undetermined number of others including gravity control, though this last still flounders in the most elementary basic research stages. Not all of these are practical in all three environments —atmosphere, ionsphere, and exosphere. Thus, unless some major technological break-through occurs, as in being able to control local gravitic fields, the propulsion system of tomor-

Kraft Ehricke's solar propulsion system is another new power concept. Future will tell . . .

A piece of hardware we can see, this REDSTONE ballistic missile represents the closest advance man has made to the future age of flight. Now being weaponized by the Army, this missile is a liquid fueled rocket.

row will probably be a combination of two or more.

Nuclear propulsion possibilities break down evenly between fission and fusion. One in each case involves the use of nuclear power as a heat source to expand and raise the temperature of a gas, either air drawn in through an inlet or, in the case of space flight, some light gas that is integrally carried on board.

In the case of fission, the ability to design a reactor to supply the necessary heat exists. What doesn't exist, however, are materials capable of standing up to the temperatures that would come with any material improvement over present thrusts. The one singular gain over conventional chemical systems for airborne operations would be in endurance.

In space flight, even this advantage would be lost, for while the fuel supply might conceivably be "limitless," range would be limited by the volume of gas that could be carried.

In theory, a fusion system could be developed along similar lines, but the same materials limitation applies. It is doubtful if, under present concepts, such a nuclear rocket or ramjet will ever reach wide acceptance, whether it be based on fission or fusion. Particularly in the case of manned applications, the problems of shielding are severe. This is also true in ground handling.

The other two possible nuclear approaches entail use of the nuclear reaction not only to heat and accelerate exhaust particles, but also as the source of the particles themselves. While it is theoretically possible to hold and contain a controlled fusion or fission reaction out in space well aft of the vehicle, thus perhaps obviating the materials problem (the fission bomb generates temperatures on the order of 50 million degrees Kelvin; fusion, 100-to-200 million), this has yet to be done successfully in the laboratory. Work is now in process to attempt it, however. It is a possible answer to some future propulsion needs, but the engineering of such a capability into practical vehicle presents appalling obstacles.

Nuclear power, however, does stand out as the white hope in almost any propulsion system of the future, not as a source of heat or as a rocket itself but as a source of electricity for powering other systems.

The most promising of these at the moment is ion propulsion, where charged particles are accelerated either electrically or magnetically through a kind of inflight linear accelerator. Though there are two distinct schools of thought, due largely to some of the problems encountered with extremely high voltages, magnetic acceleration appears to be more practical. The main disadvantages of either electrostatic or magnetic ion systems, however, are that thrusts obtained are relatively small when thinking in terms of escape from the earth's gravitic field, and as in the case of the earlier nuclear systems, the material to be ionized has to be carried for space flight.

But there are certain distinct advantages. For one, being an electrical rather than a heat engine, there is no theoretical limit to the amount the particles could be accelerated except that imposed by relativity, which is the speed of light. The practical limit, of course, is the amount of electric power which is available.

Such a magnetic accelerator would probably look much like a ramjet, and in fact might actually work as a "zip" fueled ramjet in the atmosphere, switching gradually over to magnetic acceleration as it rose into the ionosphere where virtually all the particles are already ionized.

Nobody seems to doubt that such a vehicle would automatically include a nuclear electric power source. Radiation from the reactor would probably also be used to ionize the propellent.

The photon rocket is a theory. It would use light for thrust. The idea is based on Relativity's assumption that energy (light) has mass, thus permits utilization of momentum transfer.

Theoretical calculations done on photon propulsion indicate that it would be most useful probably for space travel over great distances—outside the solar system.

Another kind of propulsion that might find practical application in free space but within the solar system, as in an artificial satellite or some other vehicle that was never concerned with operation within the earth's atmosphere, would utilize solar power. Large mirrors would gather the sun's light and use it to heat hydrogen or some other light gas.

Research into anti-gravity takes various courses ranging from theoretical calculations and subnuclear studies with bevatrons and the like to simple empirical work on the relationship of gravitic and inertial mass. Basically what still seems to be needed is some break in the laboratory or in the calculations that would point the way in which to proceed.

Gravity remains probably the most baffling mystery facing science today. Solution of that mystery, however, would bring a greater revolution in man's approach to his environment promised by nuclear power.★

FUSION FOR FLIGHT

A major goal in researching propulsion systems of tomorrow is development of an idealized nuclear rocket based on controlled fusion. The first step is to find a means of containing such a reaction. It is believed that fusion occurs at the sun's center at 20 million degrees and at a pressure of 400 billion atmospheres. At normal pressures it's estimated that the thermonuclear reaction would be self sustaining at about 100 million degrees.

In this connection it's significant that Britain's Atomic Energy Authority is building equipment at its research establishment at Harwell, Buckinghamshire, to do just this. It will consist of a "huge" glass container, in the center of which the reaction is to be contained by magnetic fields. The AEA claims to have already produced temperatures of two million degrees in small scale equipment without having caused damage to the container.

Cold fusion is another possibility. This involves catylization by the negative mu meson of thermonuclear reaction at reasonable temperatures, but with a full release of energy. This reaction has been observed by Dr. Luis W. Alvarez in a hydrogen bubble chamber at the University of California at Berkeley. Provision of an adequate, controllable source of negative mu mesons presents formidable problems. This work is still at the level of basic theory.

Meanwhile work is continuing in Britain, Russia and the U.S. to contain the hot reaction magnetically. An excellent summation of U.S. efforts in this field was recently given by Chairman of the Atomic Energy Commission, Lewis L. Strauss:

"In seeking the means of heating and confining the ionized gas, the scientists in the Sherwood Program (The Atomic Energy Commission's code word for the controlled thermonuclear program) are working with what some of them termed a 'Magnetic Bottle.'

"Electrically charged particles can be controlled by magnetic lines of force, supplied by suitable coils or by powerful electrical currents passing through the plasma itself.

"The magnetic lines of force cause any ionized particles to be deflected whenever it tries to cross them. The particles, instead of crossing the lines, are compelled to spiral around them. Thus, with the 'Magnetic Bottle' we seek to throw up invisible barriers to prevent the plasma from coming into contact with the walls of the tube.

"The scientists believe it will be possible, in such a system, to contain the plasma at a temperature of more than 100-million degrees, while the walls of the container remain relatively cool, or at least well below the melting point of the material.

"Here we come up against another baffling problem, perhaps the most difficult problem of all. 'How do we set about making the Magnetic Bottle as nearly leakproof as possible?' When the magnetic lines are employed as barriers against escape of the plasma, pressure is built up inside the lines with resulting instability of the plasma. The lines behave much like rubber bands. They're inclined to bend inward and let the plasma flow out around them. Our scientists are hard at work at the present time on this problem of instability.

"The magnetism must be just strong enough to confine the ionized gas at the right density and temperature and to maintain that confinement long enough for a reaction to take place. Since the reaction raises the temperature, the magnetic field must have variable qualities. It must grow stronger when necessary to keep things in balance. We must be able to draw power out of the thermonuclear machine without disturbing its tricky balance.

"In our research on this particular problem, some of our scientists are working with what is known, in the parlance of the laboratory, as the 'pinch effect.' They are trying to regulate the strength of the magnetic field, and obtain a direct interplay between the magnetic energy and the energy of the plasma; in other words, to produce a balance.

"A heavy current, such as a bolt of lightning, can squash a copper drain pipe through which it passes. The 'pinch' is the same phenomenon in a gaseous discharge. This is based on the familiar fact that parallel circuits carrying currents in the same direction attract each other.

"In applying this fact to controlled thermonuclear research, the scientists are seeking through heavy discharges of electricity to 'pinch' the atoms of the plasma together and suspend them in a thin line away from the container.

"Interesting results are being obtained in this particular effort, but the problem is far from being licked; perhaps even years from its solution."

"We have produced very high temperatures for the briefest fraction of time from these 'pinched' discharges. But the time during which these can be maintained, at present, is reckoned only in microseconds. As yet, the 'pinch' is not fully stable.

"And, of course, to be valuable for the purposes of producing power, the atoms to be fused together must be held in a tight bundle long enough and at a temperature high enough for an appreciable number of them to fuse. Furthermore, the energy output must far exceed the amount of energy that is required to produce the reaction.

"As I stated at the beginning of my remarks—I should like to emphasize again—we are making progress, but the problems are formidable."

Three nations have made public announcements that they are working towards controlled nuclear fusion. They are the U.S., Britain and the Soviet Union. The latest position report on the British program is noted above. The Russians, as usual say little. However, it's known that their thinking in this connection, at least, is very advanced.

U.S. progress can best be described as at the stage where scientists are seeking to get to a stage comparable to the first fission reactor which was built by Enrico Fermi's group in 1941. As of April 1, according to AEC's Chairman, "There has been nothing yet that could be described as a major breakthrough."

Efforts to achieve controlled fusion, however, are getting a $10-million boost from private industry. The Texas Atomic Energy Research Foundation last month signed a contract with General Atomic Division of the General Dynamics Corporation for a four-year research program in the field of controlled thermonuclear reactions. The Texas foundation is supported by private electric power companies operating in the Southwestern United States.

Though their objective is controlled fusion for the production of electric power, any such reaction that worked safely and economically would be a major step forward in the search for a fusion rocket. Research under this project will be carried on at General Atomic's new multi-million dollar John Jay Hopkins Laboratory for Pure and Applied Science at San Diego.

Atomic Power Packages For Missile Launching Sites

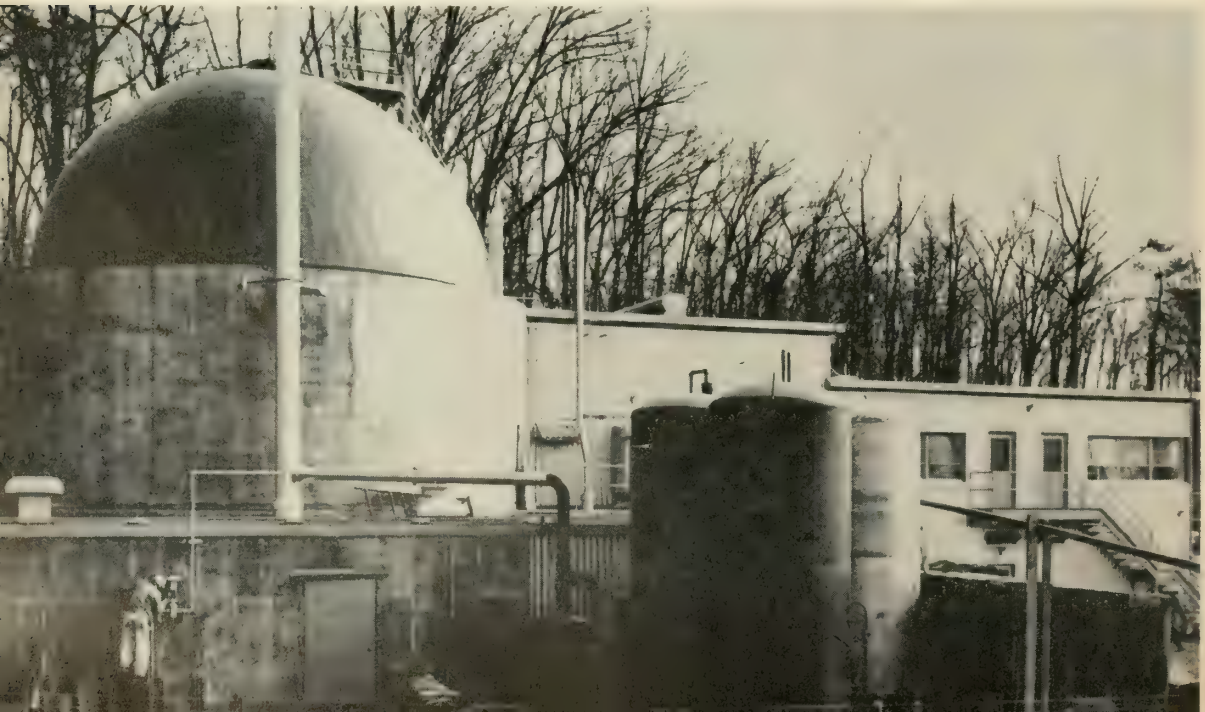
AS MILITARY strategy and tactics enter the era of operational missiles like *Snark, Navaho, Bomarc, Thor, Jupiter, Atlas* and *Titan,* problems switch from exciting to essential.

It's one thing to build a missile and test fire it from point A to point B. It's quite another to develop reliable, mobile support equipment for servicing and firing missiles from any point in the world as required by a military situation.

The primary task is development of a source power to keep an operational missile base functioning. There are crews' quarters to be supplied with heat and light; radar and other electronic gear to be powered; gantries and launching gear to be powered; oxygen to be separated from the air, purified and liquified; fuel and oxidant to be pumped, etc.

Ideally this power unit should be air transportable—perhaps ultimately air dropable—and it should contribute a minimum to logistical supply problems. It should be an atomic power plant.

Recently the first test prototype of just such a power plant began operating at the Army Engineers' Research and Development Laboratory at Fort Belvoir, Va. Heavily encumbered with extra-special safety shielding and precautionary measures because of its proximity to the nation's capital, the Army Package Power Reactor, APPR-1, is anything but packageable and anything but air transportable. However, its basic components, stripped of the probably-unnecessary additional "catastroph shielding," form the basis of just such a mobile unit.



At the present time a joint Army-AEC program has been established with the objective of developing a family of nuclear powerplants to meet the requirements of Army, Navy and Air Force. The large plants will be capable of use in areas where logistical support is difficult, costly, or vulnerable to interruption by enemy action.

Smaller plants are to be developed as mobile or semi-mobile compact powerplants for support of military operations in theaters of operations and for emergency power requirements.

The great military advantage of nuclear power is the elimination of all but a small fraction of the logistic effort which otherwise would be required to transport and store bulky conventional fuel.

The Army Package Power Reactor, APPR-1, is designed to operate at full power for a year and a half on a single charge of nuclear fuel, which

General view of the Army Package Power Reactor, with the vapor container at left. This heavy concrete dome is a major part of the extra precautionary measures taken because of the plant's proximity to the nation's capital.

is smaller than a barrel and weighs only a few hundred pounds. Over the same period a comparable conventional plant would consume some 60,000 barrels of fuel oil, equivalent to the capacity of a medium-size tanker.

Our Arctic base system is a good example of a power requirement where use of nuclear power offers a great advantage. Ship supply is seasonal, limited to the short ice-free period of less than 60 days each year. Unfavorable weather may completely throw out of adjustment the re-supply schedule for any one year to say nothing of what enemy attack would do.

In more temperate climates there are also bases which in ordinary times are subject to delay in re-supply due to their remoteness. In time of war their existence at the end of long, vulnerable supply lines is precarious.

The use of nuclear power would reduce total supply tonnage required to support many of these bases to less than half of that required when using conventional powerplants.

In addition to the present requirements, a situation of war would multiply power requirements for military operations and disaster relief. The use of nuclear power to satisfy these demands would simplify the difficult logistic problem which they create.

The military need for a family of such nuclear powerplants was established as the result of a series of investigations begun during 1952 by the Corps of Engineers.

As a result of these studies, the Army recommended the construction of a prototype nuclear powerplant in the U.S. In late 1953 the Defense Department approved the Army's plans and requested the Atomic Energy Commission to undertake the necessary development program. Shortly thereafter a joint organization was established to coordinate AEC and DOD activities in the Army Nuclear Power Program.

The Corps of Engineers representing the Army, has been given the responsibility for development of the non-nuclear portion of the plant on behalf of the Department of Defense. The Army Reactors Branch within the AEC fulfills the Commission's responsibilities for development of the reactor and associated equipment.

Three general categories of military nuclear powerplants are already being developed under this program. The first category covers fixed plants to furnish electric power and heat at remote and relatively inaccessible military installations where the cost of conventional fuel is high.

In the second category, development has been started on mobile nuclear powerplants for support of military operations and for emergency power systems. The objective is to develop plants which can be mounted on trailers, railway cars or barges, with essentially no requirements for replacement fuel or water for the duration of military operations. Two major projects are now under way.

This artist's conception shows how simplified such an atomic power plant might become once it has been stripped of such things as class-rooms and all but the most essential shielding.

The third category covers special-purpose nuclear reactor systems. Feasibility studies are being conducted on nuclear propulsion of land vehicles. The Transportation Corps is directing particular attention to a nuclear-propelled "sno train" suitable for overland supply of arctic bases.

A special-purpose reactor is about to be constructed to furnish ionizing radiation for use by the Quartermaster Corps in the irradiation and preservation of food.

Army Package Power Reactor is the first prototype of a field, military, nuclear power plant to be built as a result of this program. It has been constructed to accomplish three broad objectives:

Solve technical construction and operation problems associated with a reliable nuclear power plant.

Provide firm cost information, operating parameters and engineering test data necessary to adapt the system to a remote location.

Provide a training facility for troops and specialists who might eventually be required to operate and service remote plants.

Early in 1954 the Commission invited proposals from thirty-three major industrial firms for complete design, construction, and test operation of a prototype nuclear power plant, the APPR-1. Eighteen proposals were received in response to this invitation, and in December of 1954 the contract was awarded to ALCO Products Incorporated. The contract provided for guaranteed operation, to be established by a 700 hour performance test and a six-month operating test during which the plant would be producing usable power. The provision for a fixed price was the first such agreement in the awarding of reactor contracts.

After a survey of various locations within the U.S., and with the approval of the Atomic Energy Commission's Advisory Committee on Reactor Safeguards, the Engineer Research and Development Laboratories area at Fort Belvoir, Va., was selected as the plant's site. Since it will be in a heavily populated area, elaborate precautions have been taken in the design to insure maximum safety of operation. In addition, the reactor core will be located within a container designed to retain all radioactivity even in the event of a major incident.

The plant's design as conceived by the Oak Ridge National Laboratory and as detailed by ALCO, is based upon a pressurized water reactor operating at a power level of 10 megawatts. Pressurized water circulated through the reactor, is heated and passes to a heat exchanger where it transfers its heat to a secondary loop of water.

This heat converts the secondary water to steam which is then used to drive the turbine. The net electrical output of the plant will be utilized to supplement the Fort Belvoir power distribution system.

Construction of the plant was begun on October 5, 1955. The 700 hour performance test is scheduled to be completed before July 10, 1957. Trained men from all three military services will assist ALCO in starting and operating the plant in anticipation of the day when the plant will be turned over to the military. Experienced cadres for future nuclear power plants will be taken from this group of military operators.★

International Control of Outer Space

What Will Outer-Space Missiles and Advanced Earth Satellites Mean to World Security?

By Dr. Donald W. Cox

IN THE LONG HAUL our safety as a nation may depend upon our achieving space superiority . . . Several decades from now the important battles may not be sea battles or air battles, but space battles . . . We should be spending a certain fraction of our resources to insure that we do not lag in obtaining space supremacy."

Major General Bernard A. Schriever, Commander of the Western Development Division of the Air Research and Development Command, USAF, made this statement before the first government-industry sponsored "Space Symposium," held in San Diego last February.

The significance of this challenge by an Air Force official, who, probably more than any other man alive, is closer to the realities of the coming space flight age, is worth pondering. With the announcement of the first successful IRBM launching and hints that the first earth satellite might not be too far off, it is not too early to consider possible future legal problems involving ownership and use of the last unexplored frontier—space.

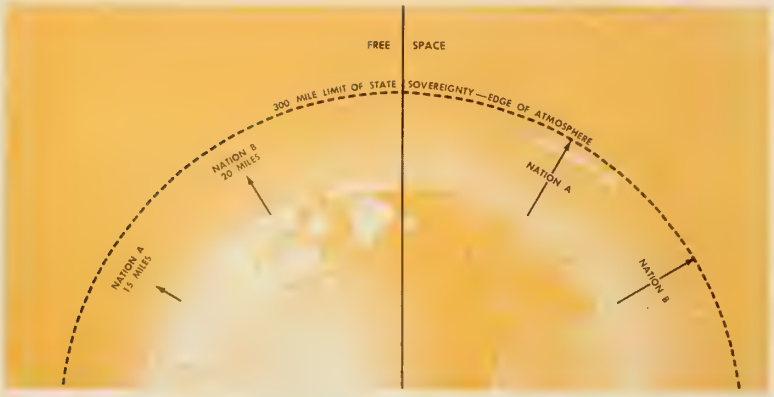
A noted international lawyer, Wilfred Jenks of Great Britain, recently summed up the need for promulgating a body of space law that will be mutually accepted by all nations.

He wrote: "It is not premature for international lawyers to give some preliminary consideration to the problems which will confront them as a matter of urgency if the current efforts of scientists and engineers, specializing in astronautics and electronics, should suddenly achieve a dramatic success . . . There are circumstances in which the possibility of developing the law on sound principles depends primarily on initiative being taken in the matter before de-facto situations have crystallized too far. The exploration and exploitation of space may proceed as slowly as the course of polar exploration or the conquest of Everest; they may however, develop as rapidly as the utilization of atomic energy, or of rocket propulsion. It is wise to be prepared for any eventuality."

With technology beating a steady tom-tom on the door of outer space, a search for a rational and acceptable space control theory is essential to help insure civilization's survival.

Theories of Space Control

In the past few years, several renowned international lawyers have taken an interest in space law in its embryonic state. Their theses have appeared in such journals as: MISSILES & ROCKETS, *Jet Propulsion, The Journal of Air Law and Commerce, The Nation's Business* and *The International and Comparative Law Quarterly.*



Excerpts and briefs of four of the leading theories will be analyzed here:

Oscar Schachter, an English international lawyer and a Director of the UN General Legal Division has fathered the Airspace Theory, which is adhered to by many U.S. experts.

Schachter's theory holds that national sovereignty upwards is limited to navigable airspace which will reach a maximum of 40 miles in the future.

This doctrine sets some legal precedents. This is evident in the multilateral air treaty agreed to by 49 nations at the Chicago Convention of 1944. Although this treaty is adhered to by most of the civilized world in granting exclusive sovereignty to airspace over national territories, it does not define the term "airspace." Because of this, there is no general agreement of height limit to sovereign control by the leading nations.

This theory is unrealistic since nations today do as they please except where treaties or their own best interests dictate otherwise. Space law like international law, therefore, will probably develop according to the relative

Shachter's "Airspace" theory—State sovereignty is limited to the height at which aircraft and balloons can operate.

Jenk's "Free Space" theory—State sovereignty is limited to activities within the limits of the earth's atmosphere only.

power of various nations instead of through any master plan. Failure to perceive the power realities is the major flaw in the workability of this theory.

Jenks' Free Space Theory

Mr. C. Wilfred Jenks, L.L.D., an Associate of the Institute of International Law at Cambridge, England, has written "International Law and Activities in Space," (1956), in which he propounds a *Freespace Theory*. In a 6-step program, he theorizes that:

(1) The appropriation of outer space by any one nation is impossible because of its nature. State sovereignty is limited to activities within the atmosphere with control similar to that "exercised in territorial waters or over a wider maritime frontier belt."

(2) Jurisdiction over space activities should be vested in the U.N.

(3) Failing this, jurisdiction should be determined by analogies to maritime and aviation law.

(4) Rules will be necessary to protect national authorities in space.

(5) The sovereignty of the moon should be vested in the U.N.

(6) The natural resources of the moon should be vested in the U.N.

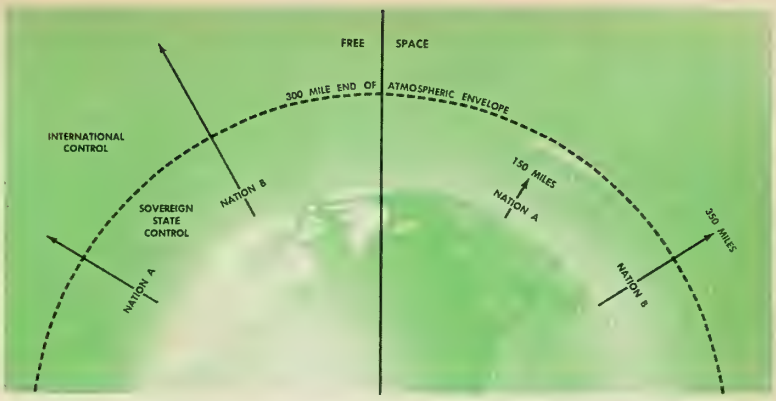
Although Jenks' theory appears to be more realistic than Schachter's from a power competition standpoint, it, too, would establish an illogical power control limit at the edge of the atmosphere. Will those nations which perfect a device to penetrate outer space submit to such a limitation?

Some moralistic nations might acquiesce to such a hypothetical limit, but not immoral ones.

Haley's International Unanimity Theory

Andrew Haley, General Counsel for the American Rocket Society and one of the two most prominent international space lawyers, has written several articles on space law. In one of his more comprehensive tomes, he propounds a theory which we will call the International Unanimity Theory.

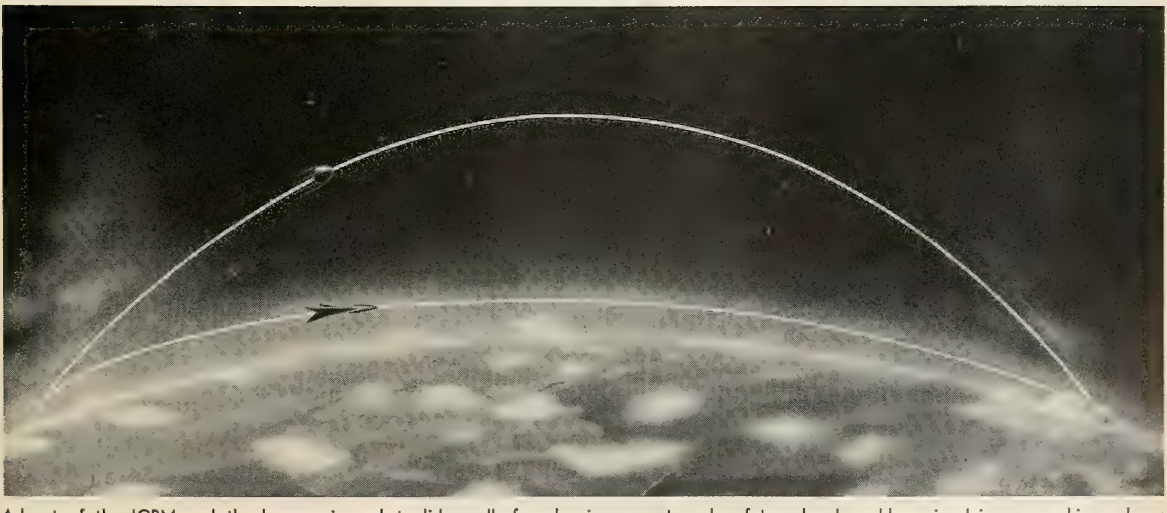
Haley theorizes that areas above the atmosphere (roughly 300 miles and up) *might* be subject to sovereign control by one or more nations. But the now historic fact that no nation objected to the plan to send earth satellite vehicles over their sovereign territories during the IGY, leads Haley to conclude that the sovereignty of space has been, ipso-facto, given to the U.N.



This mutual understanding will undoubtedly continue as long as outer space is to be used for peaceful, exploratory purposes, or as long as no one nation has the ability to intercept a satellite or space missile. Haley feels that the "scientists in the IGY Program have benefited mankind as a whole in a field where the lawyers might well have failed."

He says that the present body of international law, based on maritime jurisdiction and restricted aviation law is entirely "hostile" to the realities of space flight and is therefore inadequate. This inadequacy applies to both civil space flight rules and rules of space war. This is why a new system of space law, under the U.N., is needed.

Haley's plan calls for a mutual agreement on space communications. He rules out the possibility of any nation, with outer space capability, breaking a U.N. agreement and offers no plan if such an event should occur, putting his faith in the peace making machinery of the U.N.

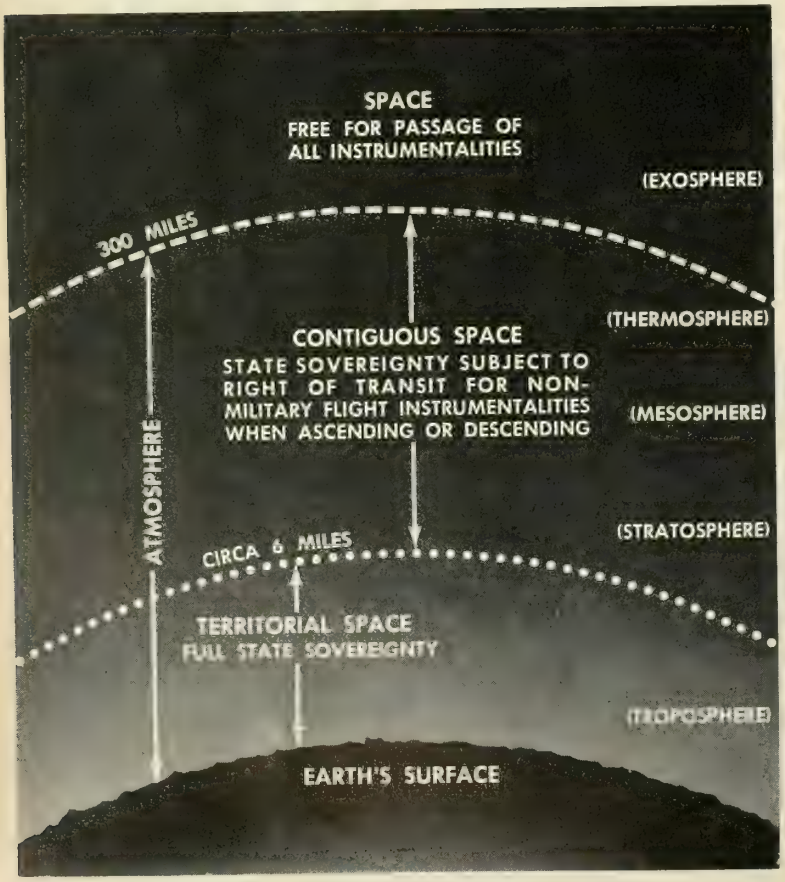


Cooper's "Control" Theory

John Cobb Cooper, the Dean of American International Air Lawyers,

Haley's theory—Extra-atmosphere "might" be subject to sovereign control; with international control for peaceful purposes.

Cooper's control theory—Sovereignty extends as far as a nation is able to govern those events occurring over its territory.



Advent of the ICBM and the hypersonic rocket glider calls for planning now to solve future legal problems involving ownership and use of space. Regulations are needed to insure peaceful exploration of our last frontier. One theory calls for a uniform code covering such activities as: instrument-carrying missiles and satellites, space radio communication, navigation, space stations and passenger transport.

An artist's view of the artificial earth satellite and the moon as seen from outer space. Fact that it is to be sent aloft during the IGY program should spark public interest in space law.

formerly Chief Counsel for Pan American World Airways and currently a member of the Institute of Advanced Studies at Princeton, has propounded a Power Theory of Space Control, which is unlimited in its scope. It is based on the assumption that a nation's ability to govern activities over its territory varies only with the nation's ability to penetrate up into space.

Cooper's "Tri-space-level" theory, as adapted from the Journal of Air Law and Commerce.

According to this theory, one nation may not be able to launch a vehicle which can escape the confines of the earth's atmosphere—while another one may be able to reach out well beyond the space frontier.

Realizing the efficacy of potential future space rivalry, Cooper proposed that an amendment to the 1944 Chicago Convention be adopted to restrict space power enthusiasts.

He feels that full state sovereignty could be maintained in the territorial space between the ground and a 10 mile high altitude in the troposphere. However, he felt state sovereignty should rule between the 10 and 300-mile levels, in what he termed "contiguous space," subject to the right of transit for flight instrumentalities when ascending or descending.

Space itself, he feels should be kept free for the passage of all intrumentalities, military or civilian, with any nation having the right to launch space flying vehicles as high and far as they wish.

Such an eventuality was predicted by General Schriever at the first Space Symposium last February, when he supported the concept of using ICBMs as a lever for the U.S. exploration of Space. He emphasized the direct military importance of space to the U.S. and added that the nation's prestige as a world leader "might well dictate that we undertake lunar expeditions and even interplanetary flight when the appropriate technological advances have been made and the time is ripe."

However, according to Haley, Cooper's rule of space control "presents the disquieting prospect that a state with extraordinary scientific resources could extend an empire into deep space. It is a counterpart of the might makes right principle which pervades maritime law and kept England mistress of the seas for centuries. This rule . . . imposes a limit over national sovereignty." This would give Cooper's theory an empirical limit.

The trouble with Cooper's control theory is that sovereignty is limited only by relative state power.

Nations that possess the capability to blast any satellite or missile from the skies overhead, regardless of their purpose, could do so at will, while other nations would be helpless to do anything about various types of spacecraft passing over their territory or to intervene in support of a friendly space exploring nation.

The concept of space ownership as envisaged by these four theorists does not call for a universally agreed space code.

However, certain common assumptions seem to be held by all the theorists studied, regardless of their differ-

ences on application of individual theses of space law and rules.

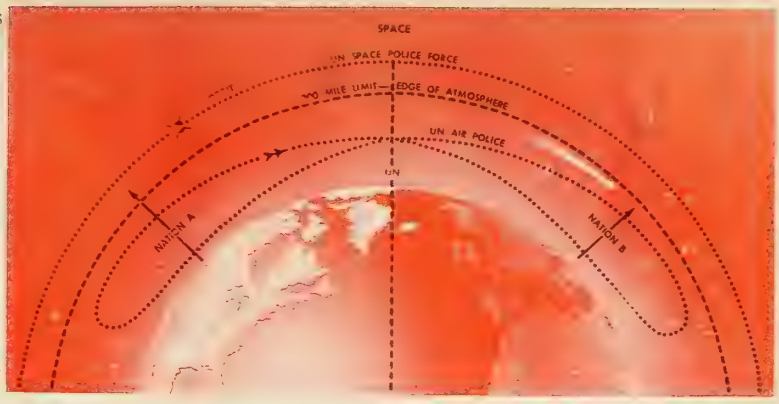
However there is general agreement that there is an inherent conflict between the doctrine of freedom of the seas and that of state sovereignty over territorial airspace. Rules for the former seem to be more applicable to outer space vehicles than the latter.

The inability of present rigid "air curtains" over fixed territorial boundaries, to adapt themselves to the constant changes of spatial relationships of a space vehicle, due to the rotation of the earth, is the logical determinant which negates the present state sovereignty air law.

All four theories propose some limit on national air sovereignty, which should be enough to seal the coffin on this present doctrine and to prevent its application to space flight.

Because missiles and space stations would be constantly changing positions, new, progressive legal regulations are needed to insure the peaceful exploration and exploitation of space.

Jenks proposes eight such regulations which still need to be written and agreed upon by all the nations, in a progressive series of steps. International uniformity will be necessary in most of these rules to guarantee civilized activities in space and to keep space instrumentalities under proper control. The legal regulations which he prescribes would encompass the following:



(1) Instrument-carrying missiles and satellites; (2) A Navigation code in space; (3) A space radio-communication code; (4) Certification of space navigators and other space persons; (5) Rules governing construction of space stations, bases, etc.; (6) A space rescue code; (7) Rules governing the carrying of passengers and goods; (8) Rules determining the law applicable to legal transactions occurring in space.

In preparing an ultimate space law code, we can learn much from the "freedom of the seas" maritime law established by Grotius.

Need for a New Theory

There is an important omission in all four theories of space control: recognition of the need for a UN space police agency to control and patrol the interplanetary regions.

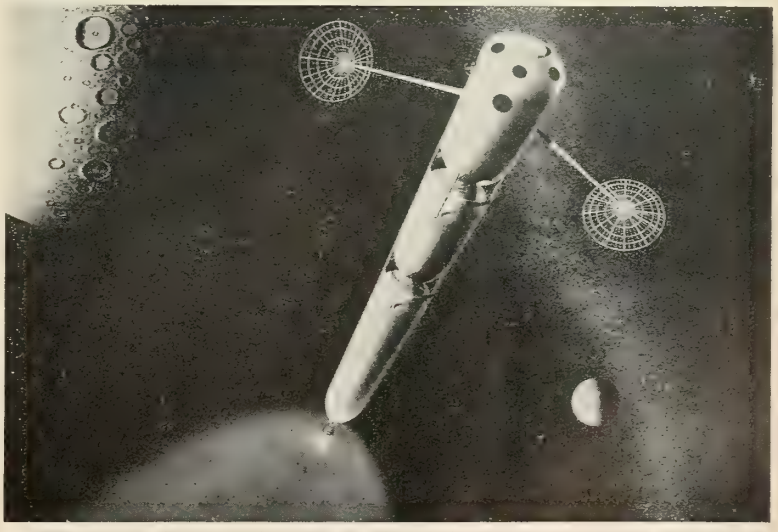
The precedent for the feasibility of such an international space police force has been the relative success of the recently organized first international police force which has been operating on the ground only in the disputed areas between Egypt and Israel. To make sure that any power-mad nation or nations does not usurp their free space prerogatives, a police force will have to come into being. The vehicles could be supplied by the major earth national powers, but the crews could be composed of space police-navigators recruited from secondary or neutral UN powers (much like the present Suez Police Force). Space control stations on earth could also be supervised and monitored by UN designated teams, even though constructed and owned by sovereign nations.

An "International Space Force" theory would have both United Nations air police and a UN space police force.

Without a permanent UN space police organization, in advance of any space dispute, Haley's *International Unanimity Theory* is in danger of being compromised.

Haley hits at the necessity of guaranteeing the joint world ownership of space in the following statement:

. . . "These principles must necessarily have only interim application, for there must be a basic principle that the regions beyond the aeropause may be called by no nation; mankind may make only such utilization of space as will be for the benefit of all mankind and to the detriment of no other intelligent creature."



The expansion of the first UN police force's duties in the Suez dispute points up the faith which the Free World has in such an organization.

The extension of the UN's control to the upper air and outer space regions with its own air and space force is a need which merits immediate consideration for initial planning purposes.

An international air-space police force could be established in a series of steps, with the conventional UN air police force patrolling the air over the Poles, oceans and uncivilized desert and jungle regions.

Such experience would provide the force with valuable insight into the greater problems with which they will have to cope when their duties are extended to the upper atmosphere and eventually to outer space.★

Note: The views expressed in this article are the author's and do not necessarily reflect those of The Martin Co.

When space becomes a highway, who will control the traffic.

SHIPS for SPACE

Some systems considerations on high performance power plants

By Dr. Peter A. Castruccio

Westinghouse Electric Corporation
Air Arm Division

FIRST ESSENTIAL for practical space-flight is an economical propulsion plant. Present-day power plants are almost adequate for exploratory expeditions, but they do not fulfill the requirements for military usage of spacecraft. Military vehicles should possess mobility: to maneuver essentially at will, to deploy in formations as required by their mission, and generally should adapt to a wide variety of kinematic and dynamic conditions as may be dictated by the maneuverings of an intelligent adversary.

Among the missions which military spacecraft will be required to perform are: reconnaissance of enemy territory, bombing missions, rescue operations, refueling in flight, and battles with other ships, stemming from the adversary's desire to thwart these missions.

These requirements necessitate that military ships have a sufficient "acceleration reserve" above and beyond the bare minimum necessary for takeoff and subsequent landing. These craft must be able to endure prolonged periods of sustained, even though not intense, acceleration.

The basic, and only propulsion system so far considered practical for space flight is the reaction principle, based on the law of conservation of momentum. According to this law, if a body of mass M + m ejects a fragment of itself of mass m with a speed v, the body M will receive a "recoil" speed equal to $\frac{mv}{M}$.

This is true for a "one-shot" ejection. If the ejection becomes continuous, as in a rocket motor, the law of recoil states that:

$$a\ M = q\ v \qquad (1)$$

where a is the acceleration imparted upon the mass M, v is the jet velocity, and q is the mass ejected per second (flow). It should be noted that (1) is only true instantaneously: as time progresses, the mass M will constantly diminish by the amount of the ejected mass, so that the acceleration will increase as time goes on (if q and v are maintained constant).

From Equation (1) we derive this expression for the acceleration:

$$a = \frac{qv}{M} \qquad (2)$$

This means that a ship of mass M can theoretically achieve any desired acceleration by using a sufficiently high qv product.

A space vehicle with high acceleration reserve should be designed to use as little reaction mass as possible in order to make the reaction mass last for as long as possible.

A reduction of reaction mass can be obtained by an increase in the jet velocity v, maintaining the product qv constant. Equation (2) shows that as far as acceleration capabilities are concerned, we can trade indifferently reaction mass for speed of ejection.

The Power P required from the ship's power plant to eject a flow of

TABLE I

Spaceship Loaded Weight = 100 Tons
Mass Ratio = 1.09
Reaction Mass = Mono-ion H^2

Acceleration	Power Output HP	Accelerating Voltage	Flow	Time to Burnout	Burnout Velocity Miles/Sec.	Time Required to Cover 50 Million Miles—Start From Rest, End at Rest
1g	2 Billion	100 KV	11.5 Oz/Sec	8.6 Hours	194	5.8 Days
0.1g	200 Million	100 KV	1.15 Oz/Sec	86 Hours	194	7.8 Days
0.01g	20 Million	100 KV	0.12 Oz/Sec	36 Days	194	21 Days

0.1g	7 Million	100 Volts	2.2 Lbs/Sec	10,000 Sec	6	200 Days
0.01g	700,000	100 Volts	3.5 Oz/Sec	1.16 Days	6	129 Days
0.001	70,000	100 Volts	0.35 Oz/Sec	11.6 Days	6	66 Days
0.0001	7,000	100 Volts	0.035 Oz/Sec	116 Days	6	244 Days

The practical realization of a high performance rocket ship hinges upon three basic developments:

1. A means to achieve high jet velocities.
2. Development of power plants of high specific power.
3. Development of energy sources of high specific energy.

A practical means to achieve high jet velocities is the acceleration of charged electrical particles.

A body of mass m and charge e, in passing through an electric field of V volts acquires a speed:

$$v = \sqrt{2\frac{eV}{m}}$$

mass q per second at speed v is ½ q v^2. By substituting (2) in this latter equation, it is easy to show that the required power is:

$$P = \frac{1}{2} M a v$$

This means that, for a given ship mass and acceleration, the power required from the ship's power plant increases directly with jet velocity (and inversely with the flow of reaction mass): thus a reduction in reaction mass can be achieved only at the expense of increased power.

Let us also assume for simplicity, that the reaction mass required for the trip is small compared with the ship's own mass, so that the simplified equations given above can be used; consider now two ships, starting from the same point, and of identical masses. If both ships travel with the same acceleration, one with a low jet velocity, the other with a higher jet velocity, both ships will cover the same distance in the same time, in other words, both will perform the same amount of external work. The ship with higher jet velocity will use a greater amount of energy than the other. Precisely, the energy used is proportional to the jet velocity.

This points out a basic law of the rocket motor: more power and more energy is required to perform the same amount of external work if the reaction mass must be economized.

A measure of basic rocket efficiency can be had by consideration of the following simple case. Consider a ship in a gravity-less field, starting from relative rest, and required to travel from Point A to Point B, a distance d apart.

Assume the trip is performed by constantly accelerating with acceleration a for half the distance d, then decelerating at the same rate until B is reached with the ship at rest. (This is almost optimum from the standpoint of power reduction.)

Under these conditions, the external power required to perform the trip is:

$$P_e = Ma^2$$

The power required to propel the ship via the rocket mechanism (the actual power the rocket must expend) equals:

$$P_r = Ma^2 \times \frac{M}{2q}$$

The ship's power must be greater than the external power by a factor $\frac{M}{2q}$

The quantity $\frac{2q}{M}$ can be considered as a measure of the basic "power efficiency" of the rocket propulsive system. The efficiency is obviously lower, the lower the reaction mass ejected. We reach the following general conclusions:

— Reaction mass can be economized by increasing the jet velocity.
— Any reduction in reaction mass must be paid for by an equivalent increase in energy expenditure.
— Any reduction in reaction mass must be achieved by a corresponding increase in power capability of the power plant.

It follows that a ship capable of sustained accelerations with economy of reaction mass must possess an energy source with high energy per unit weight, and a power plant capable of high power output per unit weight. Nuclear reactors satisfy the energy storage requirements; however the power plant is another matter.

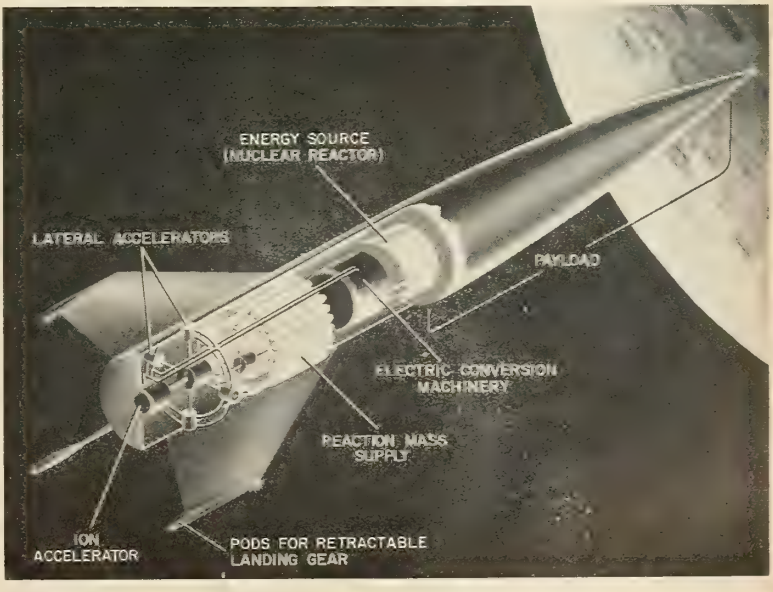
As an example of the quantities involved, consider a ship of 100 tons weight (about the size of a DC-8), to be propelled at an acceleration of 1g, with a total reaction mass of 10 tons. At a flow of 1 kilogram (2.2 lbs.) per second, the power output required will be 700 million HP. Such a ship will possess almost three (3) hours acceleration capability.

Starting from rest in gravity-less space, this ship could attain a speed of 35 miles per second, and still have sufficient reserve mass to decelerate again to rest. The total energy required to exhaust the reaction mass is equivalent to 25 lbs. of U238 at full efficiency.

By contrast, the external power required to do the same job is only about 13,000 HP.

These figures point out the huge inefficiencies of the rocket mechanism, and the tremendous discrepancies between energy requirements—which are low in terms of nuclear sources—and power requirements, which are great.

The power requirements can be reduced by either increasing the flow (the power reduces directly as the flow is increased) or by decreasing the acceleration (the power reduces as the square of the acceleration). Thus, if our ship be limited to a 0.01g acceleration, with the same flow, the power output is reduced to 70,000 HP, and the energy is reduced by a factor of 10,000. The terminal velocity reached by the ship will be only 0.7 miles per second. Table I, above, gives various relationships pertaining to the assumed ship model.



The speed is seen to depend on the charge-to-mass ratio e/m. Thus lighter particles will be speeded up more than heavy particles.

Electrons can be accelerated at higher speeds than any other particle. Electrons, however, do not constitute desirable reaction material because their total mass is but a small fraction of the mass of even the lightest substance.

In a given amount of electron-emitting metal, for instance, less than $\frac{1}{100{,}000}$ th of the metal's mass is composed of electrons.

Even if it were possible to strip a given amount of material of all its electrons, the mass of electrons thus gained would be insignificant with respect to the total mass of the material. At such low masses, extremely high jet velocities would be required and thus the power requirements would be enormous.

The converse process to electron generation is ion generation. Ions possess practically the entire mass of the reaction material, and can still be

Proposed layout for an ion-propelled space vehicle.

An ion propelled space ship accelerating at 1 g would have a power output of some seven million horse-power. A mythical cable car to the moon accelerated from an outside source would take 13,000 horsepower.

accelerated to high velocities by reasonably strong fields.

In theory, the basic concept of the ionic rocket motor is simple: the reaction material is passed through an ionizing device: the ions so formed are accelerated through an electrostatic or electromagnetic accelerator, and are ejected in space beyond the rocket.

The criteria for design of an ionic power plant depend on the intended use for the ship carrying the plant.

Generally, the known data will be: the mass of the ship, the mass of the reaction material, and the power output available from the power plant.

If the ship is required to reach the highest possible top speed with the available reaction mass without regard for the time involved, the motor should be designed to yield the highest possible jet speed. This stems directly from the "rocket equation":

$$V_f = V \times \ln \frac{M + Mr}{M}$$

where V is the final velocity attained by the rocket, Mr is the reaction mass, M the ship's "empty weight."

In this case it will be desirable at least in theory, to use ions of high $\frac{e}{m}$ ratio, namely light ions, such as hydrogen.

The characteristics of this mode of operation are: low acceleration, low values of jet flow, low power requirements:

As an example, assume a ship of the following characteristics:

Total Weight: 100 Tons
Reaction Mass Weight: 10 Tons
Power Plant Output: 10,000 HP

Assume H_2 is chosen as the reaction substance: a linear accelerator operating at 100 KV is used. The jet velocity will be 3,000 Km/sec. The acceleration turns out to be 0.000005g's.

At burnout, the ship will reach a velocity of 285 Km/sec.: it will employ a little over 180 years to reach this speed. During this time the ship will cover better than 500 billion miles (in gravity-less space). The flow will be 1.66 milligrams per second. The total need will be equivalent to 200 pounds of U238 at 100% efficiency.

In this case, the time lapse involved is undoubtedly excessive. A better criterion is the requirement to cover a given distance (in gravity-less space) in a given time for the minimum amount of power output, at a given expenditure of reaction mass. A distance d can be covered by accelerating to a given velocity, then coasting without power for a period of time, and finally decelerating back to rest: or it can be covered by constantly accelerating for half the distance, and subsequently decelerating for the other half. It turns out that, for a ship of low mass ratio, the first alternative is slightly better, if the flight parameters are properly chosen: the second method is, however, almost near optimum.

In our spaceship example, if a distance of 50 million miles must be covered in 30 days (at the specified mass ratio of 1.09), the power requirement is around 3 million HP. If the same distance need be covered in five (5) months, the power can be reduced at 24,000 HP.

At higher mass ratios, a proportional reduction in the power requirements can be secured.

We conclude that, at least in theory, an ion rocket which must reach high speeds, or which must deliver low acceleration for prolonged periods of time should have these characteristics: Reaction substance as light as possible, or with high $\frac{e}{m}$ ratio, high jet velocities and high specific power output.

If the ship's specifications call for high accelerations, sustained for relatively short times, (such as may be required to leave the Earth's gravitational field, or for certain military vehicles), then the jet velocity should be reduced, and the flow correspondingly increased, or enormous power outputs are required. For any reasonable power, the flow must be increased to such an extent that completely impractical operations result.

In our previous example of a 100-ton ship, equipped with a 10,000 HP power plant, an acceleration of 2g's calls for a jet velocity of only 4 meters/second. The corresponding flow is 500 tons/second: only 20 milliseconds are available for acceleration. (By comparison, this amount of power, applied externally, could lift the ship at a constant speed of 25 feet per second, another demonstration of the basic power inefficiency of the rocket propulsion mechanism.) Thus, the ionic rocket is definitely not a high-g device.

The ionic rocket can yield very high specific impulse; it offers in principle high performance operation at low mass ratios.

Full utilization of these advantages requires very high power outputs, and thus necessitates machinery of very high specific power, of the order of ten to fifty horsepower per pound, at high efficiencies. If such high powers are not available, we must resign ourselves to low accelerations and longer times of flight, still retaining the advantage of low mass ratios.

It is worthy of note that at high powers, efficiency is necessary to keep the heat generation down. In one of the previous examples, a power output of 3 million HP at 50% efficiency would generate sufficient heat to melt all the metal in the spaceship in less than a minute, and even at efficiencies of 95%, a good heat dissipating mechanism would be needed to insure reasonable temperatures.

Machinery such as this is completely beyond our state-of-the-art today. Thus the high-g, lightweight, high performance spaceship is still very much in the future: its realization may well require a radically new concept.★

SPACE AND SOCIETY

The relationship between astronautics and society, with emphasis on economics, has been dramatically underscored by plans for launching the IGY satellites.

Scientific achievements have, in the words of Wernher von Braun, now placed us on the threshold of the "golden technological age." He has even referred to the previous periods in civilization's advance as "bondage." Regardless of philosophy, the new scientific advances offer large fields of speculation for the economist.

In fact, von Braun says the *technological revolution* has brought about an entirely new set of unprecedented problems for the organization of human existence on this planet. Most of today's political problems are a direct consequence of this technological revolution. Capitalism, Socialism and Communism were unknown words before the invention of the steam engine. So were terms such as trade unions, raw material bases, transoceanic supply lines, and oil concessions.

"One of the most crucial problems of our times lies in the fact that the very nature of technology is dynamic, while the forms of political law and order which mankind needs for a peaceful co-existence are fundamentally static," von Braun says.

The contradistinction between the static forms of political order and rapidly changing technological conditions is likely in the future as it has in the past, to create a continuous source of conflict. Every major invention changes the basis of human existence far more profoundly than a treaty between nations or statesmen.

The technological revolution knows no national boundaries. Its smokestacks, roads, railroads, power lines and industrial cities can be found on both sides of the Iron Curtain, in America and Europe, the cradle of modern industry, as well as in historically agricultural Russia and China.

It has spread like wildfire to South America and Australia and is establishing ever firmer footholds in the darkest parts of Africa. "Even spiritual India," says von Braun, "where since time immemorial men had held that the only road to human happiness was abstention from worldly ambitions, goods and riches, is now competing with the rest of the world in the construction of hydro-electric plants and the operation of transcontinental air lines."

Although the impact of astronautics on society and our economy has been felt, if economic barometers can be projected to any degree, the advances which have been made to date have been merely small, hesitant movements in preparation for the steps which will inevitably come later.

If energy controlled by man is the first factor in his steady advance, communications is the second. Mass communication has been a dream of every progressive leader in history.

Space satellites will teach us how to achieve mass communication. The increasing demand for energy will, of course, not be truly resolved until atomic energy complements other power. To be properly effective, energy must be plentiful and within the reach of the population served. This goal will be realized shortly. The satellites will speed this up. This is particularly true in radio and television.

The radio-television industry can foresee a universal series of networks. In the United States the feasibility of this has been demonstrated. European TV is equally obvious, based on the continental performance during the winter Olympics last year. Universal telephonic facilities can be projected just as easily as TV and radio. Dial an associate in Tokyo . . .

The family farm is no longer a sound economic entity. Technological advances and the scientific advances in the utilization of chemicals have doomed the barefoot farm boy with his mongrel pup and his fishing pole. Agricultural corporations with agronomists, auditors, mechanics, packers, merchandisers and salesmen make up the personnel on today's farm. Hence the economists use the term food and fiber industry.

Take the food and fiber industry for example. Proper weather charting by space satellites will bring on a new era, enable further development of the industry, creating the opportunity for greater research across the board.

To the economist, the extended development of mass communications portends great, new markets for goods and services. The efforts to achieve a measure of productivity in keeping with the demands will tax the ingenuity of the industrial engineers. But there can be no doubt of the ability of these men to cope with the problem. Automation will play an important role, as it does even now.

The need for the increased productivity will also show up the need for additional financing. It always does. Thus, the monetary structure must be considered. During periods of controlled inflation, the prosperous periods of expansion and development, investors are eager to support new developments and risk capital is fairly easy to come by. The nation is in just such a period, and indications are it will continue in this phase for a long time.

There can be no doubt that the studies produced during the IGY will, in all phases of the social structure, have a direct effect on the economic structure. Corporations seeking diversification, and expansion will find new lines to enter. Banking establishments, too, will want to support some of these productive enterprises. As a result the basic diversification of industry will probably be accelerated.

If all of these ideas can see any measure of fulfillment, then the economist will revise his thinking on a national scale and bring it up to a truly international scale.

For man will have to concern himself with the gross universal product. The fact that the IGY satellites now are estimated to cost $57 million, much more expensive than originally planned, is insignificant. This is the most promising investment man has undertaken.

In the words of von Braun:

"It is difficult to think of a field of human endeavor that will not be involved in Man's Greatest Venture. Thus it is only natural that space flight has moved to the forefront of scientific research.

"It is the ultimate objective of our great Technological Revolution to free Man from the slavery of heavy physical labor, to elevate Mankind from its historical bondage to a race of masters, in whose service toils an army of mechanical and electrical slaves.

"This liberation through technology will enable Man to devote more time to think and to dream; it will raise all our civilizations to levels never before attained in human history. Space flight will free Man from his remaining chains, the chains of gravity which still tie him to this planet. It will open to him the gates of Heaven."

Air Force Studies Ion Power

By Henry T. Simmons

INGENIOUS NEW IDEAS in the field of ion propulsion are spurring lively government and industrial interest in the charged particle as a posible key to the next big rocket power breakthrough.

Probably the most active government agency in the ion propulsion picture right now is the Air Force Office of Scientific Research, which carries out highly advanced study projects for the Air Research and Development Command. At least three AFOSR contractors are presently working on various phases of ion propulsion:

Giannini Research Corp., Costa Mesa, Calif., ion plasma jets; Avco Manufacturing Co., Research Division, Everett, Mass., means of magnetic acceleration of gases; North American Aviation, Inc., Los Angeles, a feasibility study of ion propulsion.

In addition, several companies are investigating ion possibilities with their own funds. These include The Martin Co., Baltimore, and the newly-formed Astronautics Division of General Dynamics Corp., located in San Diego.

It is doubtful whether the dollar value of present ion propulsion research exceeds $1 million a year, but it is clear that keen interest already shown in the field presages a general expansion of such activity.

This growing interest is based on a general conviction among scientists and engineers that liquid propellant rocket combustion engines can be increased in specific impulse by only about 50% over present levels, or to a figure of about 375 pounds of thrust per pound of propellant per second. Ion propulsion specific impulse figures in the tens of thousands.

Ion propulsion has some major drawbacks, to be sure. One is the fact that any ion drive requires enormous amounts of electrical power to vaporize, ionize and accelerate the particles to high velocities. An even more important disadvantage is the very small amount of thrust developed by ion systems in relation to the mass propelled. It is so low, in fact, that no ion propulsion system so far suggested can possibly lift a vehicle from the Earth without aid from combustion rockets.

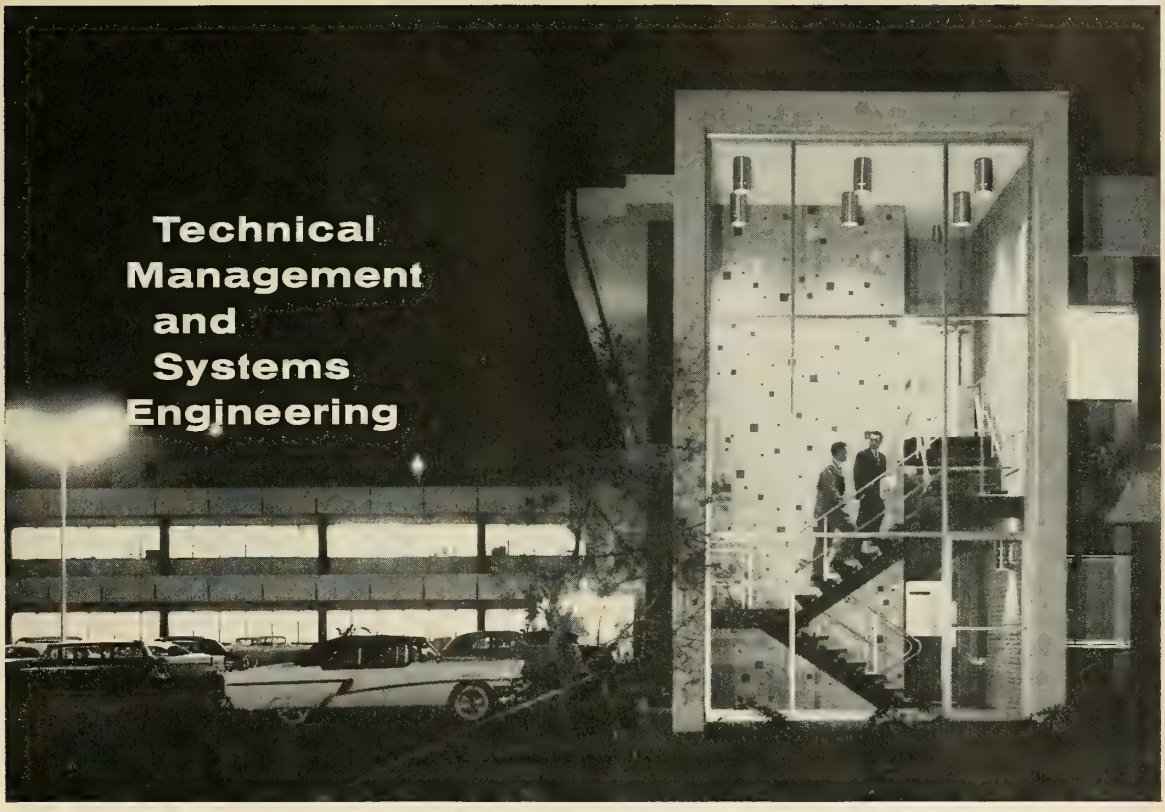
A fascinating discussion of the problems and potentialities of ion propulsion was presented to the recent spring meeting of the American Rocket Society in Washington by Martin I. Willinski, an engineer employed by the Preliminary Design Section of North American's Rocketdyne Division at Canoga Park, Calif. Willinski, together with Mrs. Elsie Orr and other North American technical personnel worked up the idea of "Project Snooper" in their spare time.

Snooper is an unmanned, ion-propelled contraption which could reach the Moon, Mars or other planets, circle them at close range, and transmit its findings back to Earth by means of television and radio. The vehicle would have a total weight of 3,300 pounds, including an allocation of 1,150 pounds for an unshielded atomic reactor, heat exchanger, turbo-generator and electrical system, 280 pounds for a heat radiator, 220 pounds for propellant, 150 pounds for structure, and 1,500 pounds for payload, including guidance.

Snooper's propulsion system would consist of two ion motors which would accelerate charged particles of cesium vapor at a velocity of 657,000 fps, compared with conventional chemical combustion exhaust velocities of about 6,000 feet per second. But the system would be limited to a total thrust of about one-third of a pound, or about .0001 gravity. This would provide Snooper with an acceleration of about .04 inch per second.

Source of Snooper's power would be a fast or intermediate nuclear reactor which could operate for a year or more before the slow accumulation of poisonous isotopes choked off the reaction. The reactor would have a total thermal output of about 1,000 kilowatts, sufficient to produce about 147 kw of electrical power. Sodium would be used as a reactor coolant, giving up its heat to mercury through a heat exchanger. The mercury would drive the turbo-generator and then flow through a second condenser-heat exchanger where it would give up its heat to a sodium loop which would circulate through the huge bat-wing radiators necessary to reject unwanted heat from the cycle. These radiators would be folded around the vehicle during the boosted portion of the flight, and unfold when the ion system would commence operation.

Cesium was chosen as the propellant for a variety of reasons, although the other alkali metals—lithium, sodium, potassium and rubidium—were also considered. Cesium has the highest ionization potential of all the alkalis, the lowest melting, boiling and vaporization points of the alkali family, and the highest density.



In the Willinski-Orr vehicle, the cesium would be contained in a tank heated by an electric blanket to about 100°F. to hold it in a molten state. An automatically controlled metal expellant bag within the tank would pressurize the vessel and force the cesium into an atomizer which would vaporize the metal at a temperature of approximately 1,500°F.

The vapor would then flow through a sintered steel distributor and then impinge upon incandescent tungsten surfaces formed into a series of ionizing grids. After a stay of only a few microseconds on the grid, essentially all the cesium atoms would lose an electron and become ions.

At this point, the ions would be accelerated across a three-centimeter gap to a velocity of 657,000 fps by a direct current potential of 27,500 volts. The cathode grid would consist of a honeycomb cross-section to assure a uniform electrostatic field in a radial direction. The authors note that this motor is based on a system proposed by Dr. Ernst Stuhlinger, research scientist for the Army Ballistic Missile Agency, Huntsville, Ala. They also make use of a Stuhlinger technique for simultaneous ejection of the electrons along with the ions by means of an emitting system located downstream of the cathode grid. The electrons thus mix with the ions at a point which does not interfere with the efficiency of the reaction and no excessive negative potential is allowed to accumulate in the vehicle.

The Willinski-Orr proposal is not related to North American's contract to study ion propulsion for AFOSR. So far as is known, there is no working model of an ion propulsion system now in existence. But the enormous potential of ion propulsion means that such hardware will be placed under contract before much more time elapses.

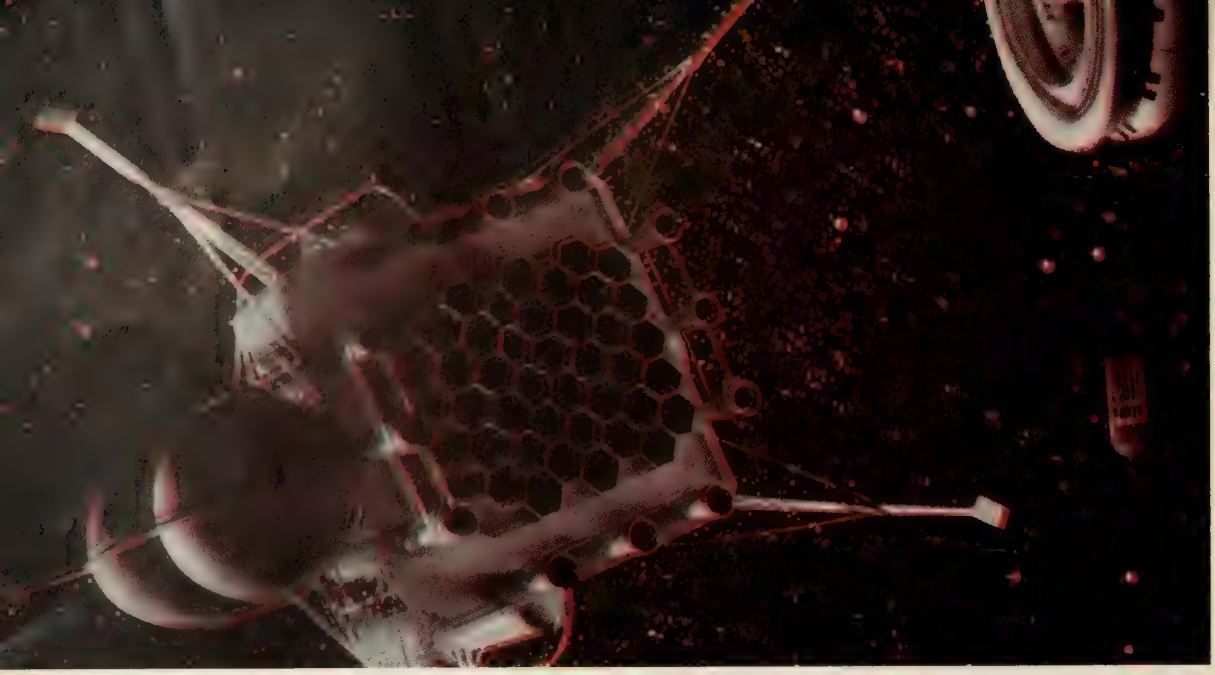
As to the task of getting such a vehicle into an orbit around the Earth, Maj. Gen. Bernard Schriever, chief of ARDC's ballistic missile program, has all but promised that the ICBM will be available for scientific research after its development as a weapon. He said in February that 90% of the unmanned space exploration projects now visualized "could be undertaken with propulsive, guidance and structural techniques presently under development in the Air Force ballistic missile program." ★

In systems engineering work, it is necessary to bring together a team that includes scientists and engineers of a wide range of technical specialties. In major weapons-systems projects, such teams will include hundreds of scientists and engineers.

But the assembly of a large group of scientists and engineers, no matter how capable they may be individually, does not of itself ensure good systems-engineering performance. The caliber of the project management has a major effect upon its technical accomplishment. It is not easy to coordinate the activities of large numbers of scientists and engineers so as not to stifle their creativeness on the one hand, nor to permit the various development sub-efforts to head toward mutually incompatible objectives on the other.

Of primary importance for good systems management is the philosophy underlying the selection of the supervisory personnel. The head of a technical activity should, first of all, be a competent scientist or engineer. A common mistake — nearly always fatal in systems work — is to fill such positions by non-technical men who have been trained only in management techniques. In the highly complex activities of major systems work, what is required is *technical management*, and of the two words, the word *technical* must never be overlooked.

In the selection of scientists and engineers for technical management, it is essential that the men chosen be broad in their training and approach. Each principal department head, for example, must have a good basic understanding of the technical facts of life of the other departments. When these people get together they need to speak a common language and understand each other's fields, so that proper decisions can be made on the many interrelated problems that come up. The higher the organizational responsibility of a technical manager, the more important this factor becomes.



The Ramo-Wooldridge Corporation is engaged almost entirely in systems work. Because of this, the company has assigned to scientists and engineers more dominant roles in the management and control of the business than is customary or necessary in most industrial organizations.

Scientists and engineers who are experienced in systems engineering work, or who have specialized in certain technical fields but have a broad interest in the interactions between their own specialties and other fields, are invited to explore openings at The Ramo-Wooldridge Corporation in:

Guided Missile Research and Development

Use of space stations or space platforms for reconnaissance purposes and possibly for military use has been proposed by many experts.

Open Sky Plan in the Atomic Age

by Dr. Edgar A. Parsons
Member, Planning Staff
Federal Civil Defense Administration

WITHIN A DECADE the major military powers will be able to activate open-sky inspection plans through use of satellite vehicles. These will contain military reconnaissance gear, camera scanning equipment, television and telemetering instrumentation.

Use of reconnaissance satellites will be an inevitable outgrowth of the IGY satellite effort. Now is the time to consider the forthcoming sky sweep from all angles.

Meanwhile the big-two are attempting to reach agreement on mutual arms inspection. Major recent events include:

—The Soviet Union's statement that it will accept a limited "open skies" inspection plan, including creation of ground inspection posts.

—The U.S. counter-offer of a three-way surveillance over Alaska, Northern Canada and Northern Siberia.

If the statesmen are groping for solutions, the scientists and engineers are already demonstrating their own solutions for the manufacture and delivery of appalling payloads in a matter of minutes to distant targets. Achievements here include:

—The United Kingdom exploded its first H-bomb May 16th.

—A new $100-million base which will serve as our first operational launching site for ICBM, and the training of launching crews has been opened at Camp Cooke, Calif.

—The tempo of firings at Patrick Air Force Base has increased.

In view of these developments, what can man do in the interim period until operation sky-sweep becomes a reality? What kind of inspection is possible meanwhile?

General Nathan Twining, USAF Chief of Staff, has summarized the danger to the U.S. of nuclear disarmament. In a statement cited by a Senate Committee on Reduction and Control of Armaments, he stated: "To give up our nuclear weapons, unless arms were truly banned, would mean victory for the Communists."

Inspection poses a tremendous problem: It is not technically feasible to detect hidden nuclear stockpiles or to accurately account for past production of nuclear weapons. Atomic bombs can be made peculiarly insensitive to instrumentation. One could be almost on top of such a bomb and not know it.

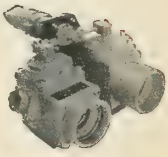
The difficulty of accounting for past production of nuclear weapons is attributed in part to three factors: (1) the relatively inaccurate character of the assay for uranium isotopic content, (2) the tremendous extent of the atomic energy plants, (3) undetectable but legitimate losses within the process.

Dr. Manson Benedict, Chief of Operation Analysis of the Atomic Energy Commission, has speculated that "from one to five bombs per year could be produced from non-accountable material if one sought to divert material improperly."

Unreliable accounting of fissionable materials, together with relative ease of this interchangeability for either peaceful or military uses, are basic difficulties which must be overcome. In an unprecedented step to help overcome these difficulties, the U.S. Government, through the Disarmament Commission of the United Nations, recently invited

The common denominator of all Hydromatics missile valves

MOTOR OPERATED CONTROL VALVES



Sizes from ¼" to 1½". Ports per MS33514, AND10050, AND10056, or special configurations. DC motor with automatic current shut-off. Response times from 0.8 to 3.0 sec. Remote light position indication. Positive locking design.

✻ Proven reliability for missile operation.

MULTI-LINE PROPELLANT VALVES

Sizes from ¼" to 4" in any combination. Motor or pressure operated. Actuating pressures from 200 to 3000 psi. Mechanically linked, simultaneous control of fuel and oxidizer lines. Available with adjustable fuel-oxidizer lead.

✻ Proven reliability for missile operation.

PRESSURE OPERATED CONTROL VALVES

Sizes from ¼" to 8". Ports per MS33514, AND10050, AND10056, and ASA flanges. Fast response rates from 20 milliseconds full stroke. Single or double acting actuators. Actuating pressures from 200 to 3000 psi. Remote light position indication.

✻ Proven reliability for missile operation.

✻RELIABILITY

PROVEN TEMPERATURE RELIABILITY
−320°F to +250°F

PROVEN PRESSURE RELIABILITY
0 to 3000 psi

PROVEN MEDIA RELIABILITY

"the scientists and officials of any nation in the world, if they believe they have a method which can completely account for past and present production of fissionable materials and to insure against improper diversion of nuclear weapons, to come forward and advance for consideration such method."

Aerial Reconnaissance

With present equipment, one plane can photograph a 490-mile wide strip across the entire United States—a distance of 2700 miles—*in less than four hours.*

There is a great difference, however, between taking photographs and interpreting the results. While aerial reconnaissance is most effective in detecting large objects, it has definite limitations: the camera eye can be fooled, there is difficulty detecting small objects, and a camera cannot look through opaque surfaces.

Today's ICBM launching and testing sites are huge and complicated agglomerations of extremely bulky equipment. As soon as intercontinental ballistic missiles become available in operational numbers, launching sites will probably be "miniaturized" and dispersed throughout the country. This would make detection extremely difficult and destruction by long-range bombardment almost impossible.

It is assumed the sites will gradually be decreased to about the size of the launching pad. For some missiles, this might be only 10′ x 10′. The missile itself, as well as its launching pad, might well be below the surface of the ground, and maintained in a state of readiness by personnel housed in underground chambers. Sliding or folding doors with great resistance to blast, over-pressure, and radioactivity, would protect the missile from bombardment, as well as from chance detection by the camera.

Although the art of subterfuge and camouflage is clearly superior to the science of aerial photography detection, if the photogrammetrist knows precisely where to look, and is provided a series of detailed photographs, large scale activity would be detectable.

Need for Speed

It was reported last fall that an Army test vehicle traveled 3,300 miles. The missile allegedly soared to an altitude of 650 miles and terminated its flight in the South Atlantic. Continued high level of progress is evident in the press statement last March by Maj. Gen. John B. Medaris, Commander of the Army Ballistic Missile Agency, that development of the Army's Jupiter is "on schedule or ahead of schedule in every respect" and will be "brought to a successful conclusion on time."

The essence of the problem is to control the military application of atomic weapons by control over the means of mass delivery.

The longer the period of time that elapses before international agreements are consummated, the greater the opportunity for deceit and subterfuge.

If the technologists and engineers produce operational missiles before the diplomats agree on an inspection procedure, no nation can be sure that the other nations will reveal the true extent of their respective arsenals. Without such certainty, of course, disarmament is not feasible, and the world must continue to live with the fear of surprise attack.

Much can be done to make the most of whatever time remains without waiting for international agreement.

We should:

(1)—*start now to train the ground inspectors and aerial technicians required to implement a reliable inspection system.*

The administrative problems can be solved now, and personnel can be trained to implement our inspection agreement without delay.

(2)—*institute a ground and aerial inspection system now with an ally.*

This would facilitate the training of ground and air inspectors and reemphasize to the world the seriousness with which the United States regards its mutual inspection proposals. Such an interchange would reveal the capabilities and limitations of ground and air inspection, and thus provide opportunity for refinement of techniques.

(3)—*negotiate for expansion of the existing military attache system.*

The U.S. and the USSR have for many years exchanged attaches, who are now customarily invited to witness certain military demonstrations. This attache exchange arrangement might serve as a nucleus for future ground inspection teams.

Initially, it would not be necessary to give these attaches permission to visit all the buildings of a particular installation. Through working level agreements, reinforced with concurrent high-level negotiations, it may be possible to facilitate mutual information exchange as an interim measure.

(4)—*institute an inspection system with a part of the USSR or a Soviet-satellite now.*

This recommendation would also facilitate the training of required inspection personnel. It would demonstrate, at first hand, the possibilities and limitations of the open skies proposal. This would provide first hand experience, without irrevocably committing the two parties.

(5)—*establish a working procedure with recipients of fissionable material to insure proper accountability and minimum danger of diversion to military use.*

Various technological arrangements will be required to insure that fissionable material will not be diverted for military purposes. To some extent agreements will provide the basis for a continued U.S. inspection and supervision over these fissionable materials; and these same arrangements might provide a basis for continued U.S.-USSR negotiations.

(6)—*pass the legislation required to establish open skies inspection now.*

Special amendment of the Atomic Energy Act was required to furnish atomic weapon information to our partners in NATO. According to Atomic Energy Commissioner Strauss, the Atomic Energy Act would have to be amended to permit foreign inspectors to examine atomic energy installations, facilities and stockpiles. If this evaluation is correct, the U.S. could not legally agree to a bona fide inspection system without new legislation. It is feasible, of course, to provide a legal basis for such inspection through the treaty device but even here ratification would require approval of the Senate. Experience does not warrant optimism for the speedy passage of such a treaty.

A comprehensive international inspection system might well be regarded as diluting the war making power of the Congress. An inspection system might also impinge upon the President's Constitutional powers as Commander in Chief. The precise Constitutional implications, of course, will not be clear until inspection agreements have been drafted. Nevertheless, the American public should be alerted now to the Constitutional implications.

Prospects for a speedy legal solution are dim indeed if inspection and disarmament procedures require amendment of the Constitution. The Second Amendment to our Constitution suggests some of the legal obstructions, which may not be insurmountable, but will undoubtedly be time consuming: "A well regulated Militia, being necessary to the security of a free State, the right of the people to keep and bear Arms, shall not be infringed." The possibility of this obstacle cropping up should be faced now and overcome.★

Rocket Engineering

By Alfred J. Zaehringer

NEW FUEL: DIMETHYL SULFIDE. West Coast researchers have found the compound valuable in controlling the combustion of monopropellant ethylene oxide. Crown Zellerbach Corp., Camas, Washington, now offers the low cost fuel, of 99% purity, in tank car lots.

ETHYL CORPORATION has patented a new process (US 2,787,626) for producing aluminum triethyl (AT). AT ignites spontaneously in air and is being tested by government and industry as an igniter and fuel for ram jets and turbojets. US Industrial Chemicals has recently made this material available in pilot plant quantities.

USE OF LITHIUM and its compounds as a missile fuel is still small. Total lithium production in 1956 was about 50 million lbs. Estimates put nondefense lithium at over 11 million lbs. The difference is now going to AEC in their nuclear program and in government stockpiles. However, Purdue University chemists now see a promising future for lithium hydrides in conjunction with boron hydrides in the preparation of exotic boron fuels.

COMPOSITE LIQUID PROPELLANTS—premixed solutions of fuel and oxidizer—are now being tested in rocket runs here in the U.S. Biggest problem seems to be stability and shelf life. Getting performances of 250-300 sec is now "routine" for many of the new high-energy liquid combinations but they start to fall apart in stability over the 225 sec mark.

INDICATIONS OF PHILLIPS PETROLEUM potential in the solid propellant field can be gleaned from these annual production figures from their Chemical Division: 235 million lbs. of carbon black, 715,891 tons fertilizer, and 56,121 long tons of synthetic rubber. The Rocket Division uses unknown quantities of all these materials for producing ammonium nitrate-type solids.

MORE ON FREE RADICALS: University of California scientists have mapped the infrared spectrum of typical atoms. The potential rocket fuels have already been studied in the ultraviolet and visible regions by others.

SEVERAL MATERIALS are compatible with gaseous fluorine at atmospheric pressure but, says NACA, only Teflon and aluminum oxide can stand up at pressures of 1,500 psig.

FURALINE III is the furfuryl alcohol base fuel used with 98% nitric acid for the SEPR 481 rocket engine. The three-chambered 481 is used on the SO.9000 *Trident* I aircraft. Total nominal thrust is about 9,900 lbs. Maximum sea level thrust is 10,500 lbs. and nearly 11,500 at an altitude of 40,000 ft. The *Trident* II is to be equipped with an improved model, the SEPR 631.

MORE NITRIC ACID ON THE WAY: Allied Chemical & Dye Corp. is adding a new nitric acid unit to its Newell, Pa. facility which will double present capacity.

SCALING DOWN a solid propellant rocket motor presents some unusual difficulties. In miniature motors of a few ounces of thrust, standard design techniques are not wholly adequate because of excessive heat losses to the relatively more massive chamber walls. NACA's Langley facility did manage to design a small rocket to deliver 3 ounces of thrust for 2 seconds. Propellant weight was slightly over 1 gram, total loaded weight was 18.5 grams. It is interesting to note that the Cordite SU/K propellant produced an I_{sp} of 145 sec at a chamber pressure of 353 psia.

Ion Propulsion and Why . . .

A Comparison of Space Ship Propulsion Systems

by Ernst Stuhlinger

Army Ballistic Missile Agency
Huntsville, Alabama

A SPACE VEHICLE, like any vehicle in any system of reference, can be accelerated in a given direction only by accelerating some mass in the opposite direction by a force which acts between vehicle and mass. The resulting movements of the vehicle and the reaction mass are governed by the law of conservation of momentum.

The main requirement of a propulsion system can be described thus: the product m.v should be as large as possible, where m is the total propellant mass, and v the exhaust velocity. An additional requirement applying to a space ship is that the ratio of the total initial mass of the vehicle to the payload mass should be as small as possible to make the trip economical.

The total mass includes the structural mass, the propellant mass, the mass of the thrust chamber, the payload mass, and, where applicable, the mass of the power plant.

A number of different propulsion systems have been suggested for space vehicles. Four of them will be considered here.

In the first system, the propellants are accelerated by heat energy from chemical reactions.

In the second, the propellants are accelerated by heat energy from a separate power source like a nuclear reactor, an electric arc, or the sun.

In the third, the propellants are ionized and accelerated by electric fields.

In the fourth, photons are emitted. They create thrust by virtue of the momentum which they impart to the vehicle when they are emitted from a radiation source.

Chemical Systems

Chemical rocket engines are the best known since they have been used successfully in many earth-bound rockets. They have the great advantage of combining the propellant mass and the power for its expulsion in the fuel-oxidizer system. No separate power source is necessary. Their disadvantage is that the exhaust velocity v, a function of the combustion temperature, is limited to relatively low values. The total propellant mass m must therefore be high. The combustion temperature is determined by the energy of combustion, by dissociation effects, and by the temperature resistivity of structural materials. Modern rocket engines have exhaust velocities of 2500 to 3000 meters per second. It does not appear likely at present that chemical rocket engines with much greater exhaust velocities will be developed in the near future for space-going vehicles.

Several studies have been published dealing with chemical propulsion systems for space vehicles. The most detailed of these, "The Mars Project" by W. von Braun,[1] provides the characteristic data of a chemical propulsion system capable of taking a space ship to Mars and back.

This system uses hydrazine and nitric acid as propellants with an exhaust velocity of about 2800 meters per second. The highest acceleration attained during the trip is of the order of one G.

The ratio of take-off weight to final weight after consumption of all fuel, is about 25 to 1. Burning time is 16 minutes. Travel time from earth to Mars would be 260 days.

Gas-Heating Systems

The next category is characterized by three different designs. The characteristic data of the first one, a propulsion system using a uranium reactor which heats liquid ammonia, can be derived from reactor design and operation data that were published recently.[2]

The second is a solar energy ship proposed by K. Ehricke.[3] The third is based on the high-intensity electric arc, a gas-heating method which may find application in wind tunnel systems.

In all three proposals, the energy source is separate from the propellant mass. This separation introduces a weight penalty as compared to the

chemical propulsion system which can only be compensated by higher exhaust.

The nuclear reactor system, in which ammonia is pumped through graphite tubes inside the reactor, provides an exhaust velocity of about 4000 meters per second. This value is limited by the heat resistivity of existing structural materials.

Using pure hydrogen, exhaust velocities of the order of 6000 meters per second can be expected. It seems that the reactor-heating method becomes superior to chemical systems only when space ships are considered whose take-off weights are greater than a few hundred tons.

The solar-powered ship designed by K. Ehricke uses two large reflectors which are formed by inflated balloons of Mylar polyester; one half of each balloon is coated with aluminum. In the focal area of each reflector there is a boiler in which liquid hydrogen is vaporized and heated to a temperature of 850°C. Blowing out through a nozzle, the hydrogen jet develops a thrust of about 160 pounds. Its exhaust velocity is of the order of 4500 meters per second. The acceleration of the ship is about 1/100 of one G.

Since the energy-producing system in this case is very light, the solar-powered hydrogen ship may well be superior, weight-wise, to a chemically propelled ship on shorter interplanetary trips. Its life would be limited, though, by the action of meteors which puncture the balloons. Even though the deflation would be very slow, one could not expect an operating lifetime of more than a few weeks.

The technique of heating a gas, or rather a plasma consisting of atoms, molecules, and ions, by a high-intensity electric arc, has been developed mainly by Finkelnburg, Maecker, and Peters[4], and by Giannini.[5] Exhaust velocities of about 6000 meters per second have been obtained.

The electric power needed to operate the high-intensity arc could be generated with a nuclear reactor driving a turbo-generator. Considering the fact that exhaust velocities of the same order can be obtained by direct heating of hydrogen in an atomic reactor, it seems doubtful whether the complicated mechanism of turbo-generator and electric arc would pay off.

Direct generation of electric power by means of radioactive isotopes has been considered by H. Kaeppeler.[6] Although this method of providing electric power would be very straightforward, it is likely that the production and handling of such large amounts of radioactive isotopes as needed would present insurmountable difficulties.

The heat generated within the radioactive substance and the structural elements of the battery would amount to at least 20 or 30 per cent of the electrical power output. Dissipation of this heat would be a severe problem.

Electric Systems

Electric propulsion systems for space vehicles were proposed as early as 1923 by H. Oberth.[7] A more detailed design and performance study of an electrically propelled space ship has been worked out recently.[8] The payload chosen for that design is 150 tons.

The primary power source is a uranium reactor which generates heat for steam production. Electric power is produced by a turbo-generator with radiation cooler. The propellant material is rubidium or cesium; these metals ionize easily and with an efficiency of almost 100 per cent, if they are vaporized and brought in contact with hot platinum surfaces. The ensuing ions and electrons are then subjected to electrical fields which accelerate them to high exhaust velocities.

The power contained in the jet increases with the square of the exhaust velocity; the total mass of the power plant, including cooler, increases at nearly the same rate. The thrust, however, increases only with the first power of the exhaust velocity. This fact is the reason why the exhaust velocity of the ions should not be too high.

A detailed investigation of a representative design resulted in an optimum ion exhaust velocity of about 80,000 to 100,000 meters per second, corresponding to an accelerating voltage of about 5000 volts. A higher or lower accelerating voltage would mean larger total mass of the ship for the same payload.

The ion thrust chambers as required for an electric propulsion system can be operated only when the space charge effects connected with charged particle beams are successfully eliminated. Neutralization of the space charge as soon as the ions have left the thrust chambers can be achieved by mixing the ions with the electrons from the electron thrust chambers.

Actually, the thrust contributed by the electrons is very small because of their small mass. However, they must be expelled from the ship anyway to keep the ship electrically neutral.

A representative space ship with an electric propulsion system, capable of carrying a payload of 150 tons to Mars and back, would have a total take-off mass of 730 tons, a propellant mass of 365 tons, an accelerating voltage of 5000 volts, a total electric power production of 23,000 kilowatts, a thrust of 50 kilograms, and an acceleration of a little less than 10^{-4} of one G.

The propulsion system would work during the entire trip, partly accelerating, and partly decelerating the vehicle. Total travel time from earth to Mars would be about 400 days.

Photonic System

The common feature of the three previous kinds of propulsion systems is that they could be built with techniques as we know them today. This is not true for the fourth kind of propulsion system, the photonic rocket.

A photonic propulsion system emits an unidirectional beam of photons. Their momentum is E/c, the quantum energy divided by the light velocity. The theory of photonic propulsion systems is based on the assumption that the photons can be created by direct and controlled conversion of matter into radiation energy according to the fundamental Einstein equation $E = m c^2$, a conversion which can be observed in nuclear processes, for example in the annihilation of an electron and a positron to form a pair of gamma quanta, but which is not yet known to exist on a technical scale.

Provided that the entire mass of the propellant could be converted into energy according to Einstein's equation, the energy content of matter is 10^{10} times greater than the chemical energy content of conventional propellants, referred to the same mass.

For a proper functioning of the photonic propulsion system, the further assumption must be made that photons of all the wavelengths generated in the conversion process can be reflected and collimated to form an almost parallel bundle. The collimating mirror must have a reflecting power of the order of 0.99999999.

If the photons are generated within a container, its walls must have a transmissivity of the same order. With lower reflectivities and transmissivities, the mirrors and walls would absorb such great amounts of radiative energy that they would vaporize immediately.

Although these requirements are still completely out of the range of present technical feasibility, it is most interesting to study the principal features of a photonic propulsion system. A number of very thorough studies on the mechanics of photonic propulsion have been published by E. Saenger.[9]

Assuming that the direct and controlled conversion of matter into radiative energy is feasible on a technical scale and that the ensuing photons can be collimated without noticeable absorption by lenses or mirrors, the relativistic formulae for mass consumption, thrust, velocity, mass ratios, and

flight times of photonic space ships can be developed. It must be admitted that the photonic propulsion system opens horizons to space travel which are entirely out of reach for "classical" designs of space ships. Since the exhaust velocity of the photons is equal to 300,000 kilometers per second, an appreciable thrust could be obtained even with an extremely low mass consumption. After a sufficiently long time of operation, the ship would approach light velocity.

The relativistic dilatation of its own time, as experienced by the space travelers, would then become noticeable. Even trips to remote galaxies could then be made within a few years as counted by the crew of the ship. The following table shows the time interval $\triangle t$, the acceleration b, and the total elapsed time t as measured from the earth and on the ship.[10]

Table I. Relativistic transformation formulae.

Earth system	Ship system
Time interval	
$\triangle t = \triangle t_0 / \sqrt{1 - v^2/c^2}$	$\triangle t_0$
Acceleration	
$b = b_0 (1 - v^2/c^2)^{3/2}$	b_0
Elapsed time	
$t = c/2b_0 (e^{b_0/c\, t_0} - e^{-b_0/c\, t_0})$	t_0

These formulae show that the relativistic effects are the same for positive and negative velocities, and for positive and negative accelerations. In particular, if a crew of space travellers left the earth on an accelerating ship and returned after some time on a decelerating ship, the crew members would find that during their absence everything on earth has aged more than they have themselves.

The difference between the time elapsed for the earth and the time elapsed for the crew is determined by the formula in the last line of the above table. Some pertinent figures of space trips made with photonic propulsion systems are listed in Table II.

While the propellant mass needed for a voyage as far as the planets would be negligible, the necessary mass ratio of a photonic ship capable of a round trip through the universe would require, for an empty mass of about 600 tons, a propellant mass equal to that of our whole earth

Even though a photonic space ship cannot be achieved with technologies which may be at our command within the forseeable future photonic propulsion studies are most interesting as speculations because they give an idea of where the limits are set in principle by the basic laws of physics as we know them today.

It seems very obvious, though, that the two main problems of the photonic propulsion principle, the conversion of matter into radiative energy and the extremely high reflectivity of surfaces, will not be solved by engineering effort alone. Both problems are of a very fundamental nature. If they are solvable at all, their solution should be expected only as an achievement of basic scientific research.

Table III shows a few characteristic figures relevant to the four groups of propulsion systems considered in this paper. It is very likely that the first trip to another planet will be made with a chemically propelled ship, simply because its techniques are well developed.

Electrically propelled ships would be more economical from a weight standpoint, but they require a longer development time. Preference should always be given to that type of propulsion system which gives the greatest assurance for the crew's safe return.★

TABLE II

Characteristic Data of Photon Space Ship *

Trip	Mass Ratio	Ship Time	Earth Time	Distance
Half around earth	1.00007	47 min	47 min	2×10^4 km
Moon	1.0003	3.5 h	3.5 h	4×10^5
Planets	1.006	2 d	2 d	10^8
d Centauri	20	3.6 y	6 y	4×10^{13}
Center of galaxy	10^4	20 y	6×10^4y	2.8×10^{17}
Andromeda nebula	10^{11}	26 y	2.5×10^6y	7×10^{18}
Round trip thru the universe	10^{19}	42 y	4×10^9y	3.2×10^{22}

* A constant acceleration of 1 g to the midway point, and a subsequent deceleration of the same magnitude, was assumed for these trips. Mass ratio is the ratio of take-off mass to burn-out mass.

TABLE III

Comparison of Propulsion Systems

Propulsion System	Exhaust Velocity (m/sec)	Acceler. (G)	Power/Thrust (kw/kg)	Technical Feasibility
Chemical	3×10^3	1...8	15	Technology Proven
Nuclear or solar power plus light gas	$4..6 \times 10^3$	1...8	20..30	Technology Known in Principle
Nuclear power plus ions	1×10^5	10^{-4}	500	Technology Known in Principle
Photonic	3×10^8	1...2	3×10^6	Technology Unknown

The Ion Rocket

The Most Attractive Power Plant for Space Flight?

Dr. John E. Naugle

Convair Division

General Dynamics Corporation

THE ION ROCKET is a low thrust system which must be placed in a satellite orbit by a high thrust chemical or nuclear powered rocket. Once there, if the ion rocket has sufficient thrust it will slowly accelerate and escape from the earth's gravitational field. With the advent of the ICBM program and high-current ion ejectors the ion rocket moves from the realm of the imagination to a candidacy for advanced research and development.

A propulsion system with ultimate exhaust velocities in the neighborhood of 3×10^{10} cm/sec. is attractive but when this is combined with a system which allows these high exhaust velocities and the rate of mass flow both to be controlled, the possibility of interplanetary space travel moves from the realm of science fiction toward reality. The ion rocket works on an entirely different principle than a chemical rocket. Many people familiar with the operation and problems of the chemical rocket are not aware of the principles of the ion propulsion system. The purpose of this article is to present a highly simplified version of an ion rocket to illustrate the basic principles of the system.

An ion rocket operates by ejecting ions at high velocities. To accelerate the ions to these high velocities the propulsion system must exert a force on them and by Newton's third law an equal and opposite force will be exerted on the propulsion system, thereby accelerating the rocket ship.

The basic difference between an ion propulsion system and a chemical propulsion system lies in the difference between an ion and an ordinary molecule. An ion is a particle which carries a net charge. An atom or molecule is normally neutral. However, under certain conditions an electron can be added or removed. This charged molecule is an ion.

Neutral molecules are accelerated and acquire high velocities through collision with other neutral molecules whereas an ion can be accelerated in an electric field. In a gas composed of ordinary molecules the directions of motion of the molecules are completely random. A cloud of ions in the presence of an electric field will all move in the direction of the field.

An ion of net charge Q, mass m and in an electric field of magnetic E will have an acceleration a, given by:

$$a = \frac{EQ}{m} \qquad (1)$$

The acceleration of dust particles or any aggregate of molecules of mass m, and net charge Q will be given by equation (1), thus from a propulsion standpoint they should also be classified as ions and considered as possible propellants.

It is customary to refer to a beam of ions as a current of given amperage. If f ions of charge Q pass a certain point in one second the current I, in amperes will be:

$$I = fQ \qquad (2)$$

if Q is measured in coulombs.

The diagram illustrates the functions which must be performed to achieve propulsion in an ion rocket. The propellant is carried as neutral molecules. These are ejected into the ion source and ionized. Ions can be formed by radio frequency discharges, arc discharges and by other ions traveling at high velocities.

Electrons are removed from neutral molecules leaving them positively charged. The electrons may attach to another neutral molecule forming a negative heavy ion or remain as free electrons-light negative ions. An electric field can then be used to move the ions out of the source.

The positively charged ions move in the direction of the field and the negatively charged ions move in the opposite direction. After leaving the source, the ions pass into region B where their trajectories are curved to bring their direction of motion out the end of the rocket. This can be done

either by an electric or magnetic field in region B.

In region C strong electric fields are used to accelerate the ions to their exhaust velocities. This is a highly simplified concept but it serves to illustrate the basic principles. It is necessary to eject ions of both signs and in equal numbers, otherwise the rocket would acquire a net charge and attract and slow down ions it is trying to eject.

The thrust F, on the rocket is given by the relation:

$$F = fmu \qquad (3)$$

where f is the number of ions of mass m, and velocity u, ejected per second. If an ion of mass m, and charge Q is accelerated through a potential V, the kinetic energy which it acquires is given by:

$$\tfrac{1}{2}\, mu^2 = QV \qquad (4)$$

Using equations (2), (3) and (4), it is possible to express the thrust in terms of the important parameters as:

$$F = I\sqrt{2mV} \qquad (5)$$
$$\overline{Q}$$

Disregarding losses, the total power P put into the beam would be VI, the thrust per unit power would be:

$$\frac{F}{P} = \frac{I\sqrt{2mV}}{\overline{Q}} \cdot \frac{\sqrt{2m}}{\overline{VQ}} \qquad (6)$$
$$\overline{VI}$$

The thrust per unit mass is:

$$F' = \frac{I}{m}\sqrt{2mV} \cdot \frac{\sqrt{2V}}{\overline{Q}} \cdot \frac{I}{mQ} \qquad (7)$$

According to equation (6) a high thrust-to-power ratio is obtained with a propellant of high atomic weight and a low accelerating potential. A high thrust to mass ratio is obtained with a propellant of low atomic weight and high acceleration potential.

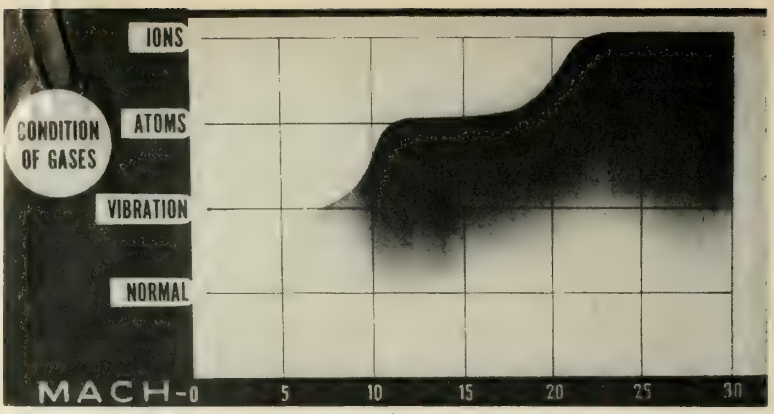

Chart showing dissociation of earth's atmosphere with increased speed. Ions from about Mach 20 and up could be used in electrical ion "ramjet."

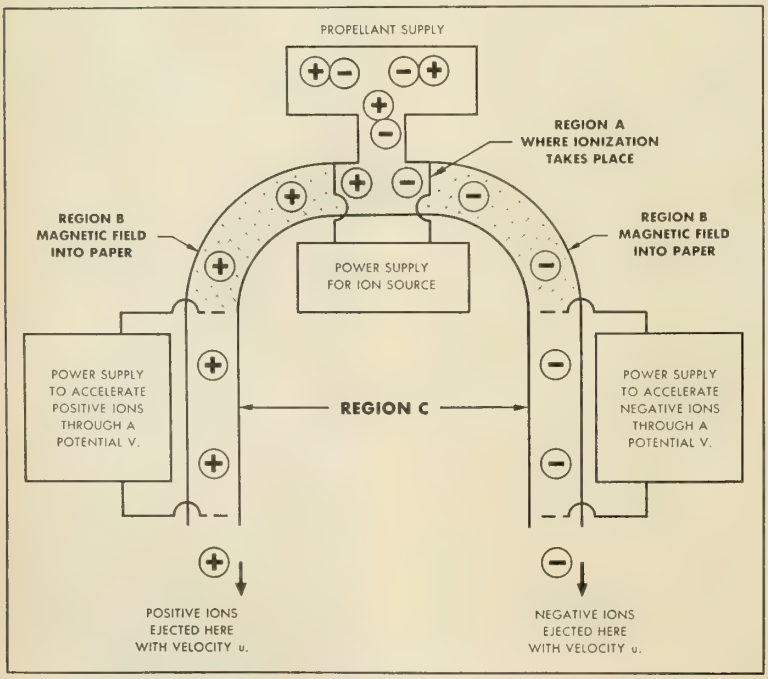
In any actual design the weight of the power supply will have to be taken into account. This power supply may be electrical energy stored in batteries, a nuclear powered generator or a device to convert solar energy into electrical energy.

One of the very attractive features of the ion rocket is that both I and V can be easily controlled. This means that both the exhaust velocity and rate of propellant utilization can be varied.

The final design would incorporate the proper propellant and a programmed flight regime to make the rocket travel the maximum distance, in the shortest length of time with a minimum initial weight.

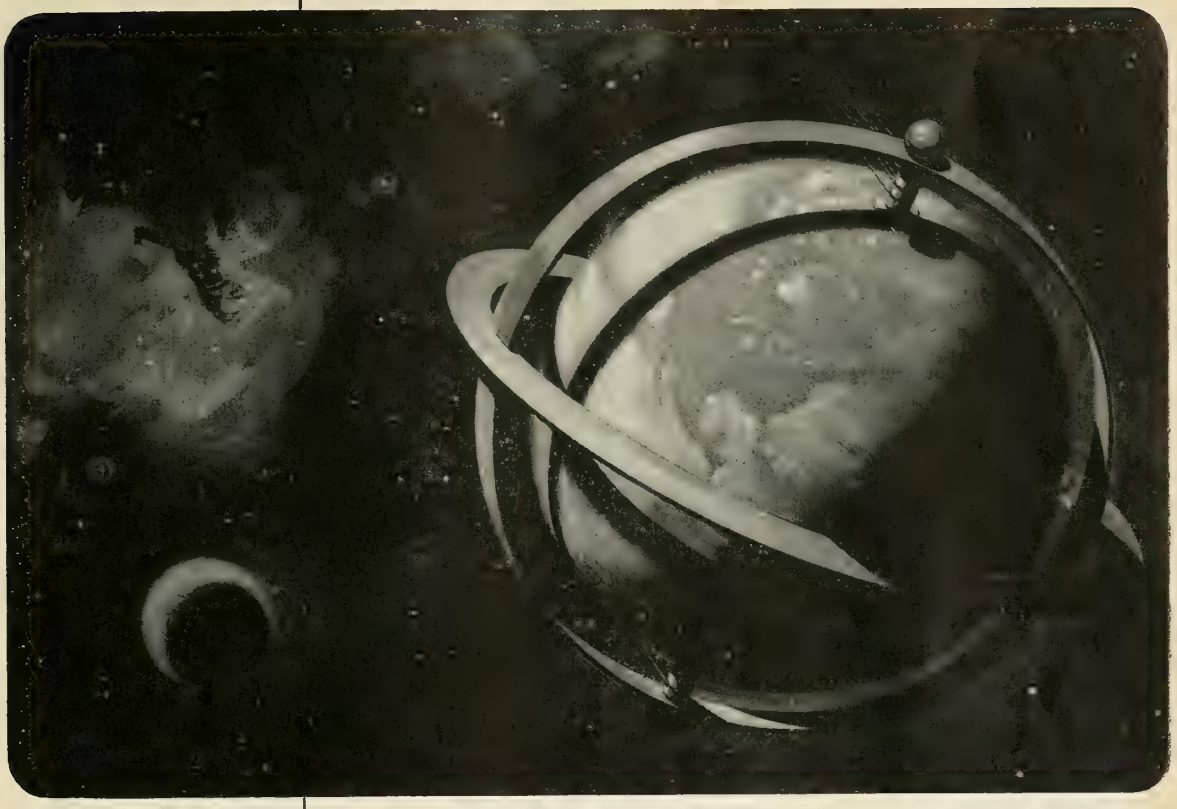
The major obstacle to be overcome to make the ion rocket feasible is the development of a high current ion source and a light and efficient power supply. The ionization process requires about 4 to 10 watts of power per ampere of ions.



The actual process as used in the high current ion ejectors is still very inefficient. It actually required about 10 to 100 kilowatts of power to produce an ampere of ions. This power, however is independent of the exhaust velocity of the ion.

If the ions are accelerated through a sufficiently high voltage the power lost in ionization can be made small compared to the power in the beam or to the kinetic energy transferred to the rocket by this process.

The present "state of the art" for ion sources is best illustrated by the "High-Current Ion Injector" described by W. S. Lamb and E. J. Lofgren in Rev. Sci. Instr. 27, 907 (1956). This machine produces a 0.75 ampere beam of 100 kilovolt deutrons.



The total power into the machine is about 170 kilowatts, the power in the beam is about 75 kilowatts or about 44% of the electrical energy is converted into kinetic energy of the ions. The total thrust from this beam however, would be only about 5000 dynes or about 10^{-2} pounds. The exhaust velocity is 4.4×10^8 cm/sec.

In summary: the ion rocket is attractive because of the high and controllable exhaust velocities, the efficient conversion of electrical energy into kinetic energy and the overall control over the propulsion system. A major effort is required to produce ion sources of thousands of amperes, which ionize and accelerate the major fraction of the propellant carried aloft. A companion effort is required to produce an efficient light weight power supply.

Schematic diagram showing the basic layout of ion propulsion system.

IMPORTANT DEVELOPMENTS AT JPL

The Jet Propulsion Laboratory is a stable research and development center located to the north of Pasadena in the foothills of the San Gabriel mountains. Covering an area of 80 acres and employing 1550 people, it is close to attractive residential areas.

The Laboratory is staffed by the California Institute of Technology and develops its many projects in basic research under contract with the U. S. Gov't.

Qualified personnel employment inquiries now invited.

Pioneers in Guidance Systems

For many years the Jet Propulsion Laboratory has pioneered in the design and development of highly accurate missile guidance systems, utilizing the most advanced types of gyroscopes, accelerometers and other precision electro-mechanical devices. These supply the reference information necessary to achieve the hitherto unattainable target accuracies sought today.

The eminent success of the early "Corporal" missile flights shortly after World War II firmly established the Laboratory as a leader in the field of missile guidance. These flights also initiated experiments involving both inertial and radio-command systems employing new concepts of radar communication. Because of this research and experimentation JPL has been able to add materially to the fund of knowledge available to designers of complex missile systems.

This development activity is supported by basic research in all phases of electronics, including microwaves and antennas, new circuit elements, communications and reliability in addition to other branches of science necessary to maintain a fully integrated missile research organization.

The Jet Propulsion Laboratory, therefore, provides many challenging opportunities to creative engineers wishing to actively apply their abilities to the vital technical problems that require immediate and future solution.

We want to hear from men of proven ability. If you are interested please send us your qualifications now.

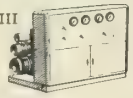
Oil free high pressure gas

FOR MISSILE PRESSURIZATION SYSTEMS

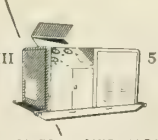
ASSEM. NO. 9200
TACTICAL DIESEL ENGINE
DRIVEN 3-STAGE 6000 PSI
COMPRESSOR FOR ATLAS MISSILE



Haskel

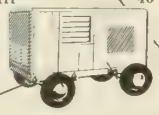
MULTI-STAGE BOOSTER COMPRESSORS compress helium or nitrogen from a variable inlet pressure source such as commercial gas bottles to a higher outlet pressure.

COMPRESSION WITHOUT LUBRICATION prevents oil contamination and insures highest purity of outlet gas.



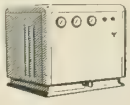
- OUTLET PRESSURES TO 10,000 PSI
- INLET PRESSURES FROM 50 PSI MIN TO 2,300 PSI MAX
- CAPACITIES FROM 1 SCFM TO 80 SCFM STANDARD
  (LARGER CAPACITIES ON REQUEST)

MODEL LS-III — 40 TO 80 SCFM



FOR TEST SITES — STATIONARY

MODEL SM-III — 5 TO 30 SCFM



FOR TEST SITES — SKID MOUNTED
AVAILABLE WITH ELECTRIC MOTOR OR GASOLINE ENGINE

MODEL LM-III — 40 TO 80 SCFM

FOR TEST SITES — PORTABLE
ELECTRIC MOTOR DRIVE — AIR COOLED

ASSEM. NO. 9315 — 1 SCFM

FOR TESTING COMPONENTS

one, two, three or four stage models available for stationary, portable or *tactical use*

engineering briefs

Robertshaw-Fulton Operates Test Facility

One of the nation's most complete facilities for testing controls and control systems used in missiles employing helium, nitrogen, oxygen or other gases as propellants or pressurization agents is now in operation at Aeronautical Division, Robertshaw-Fulton Controls Co.

The helium test equipment is capable of simulating internal environmental conditions encountered by aircraft and missiles.

According to Robert L. Wehrli, vice president and general manager of the division, the facility will be used principally for testing the company's line of aircraft and missile controls. In addition, testing assignments for outside companies and military agencies will be conducted on a contract basis.

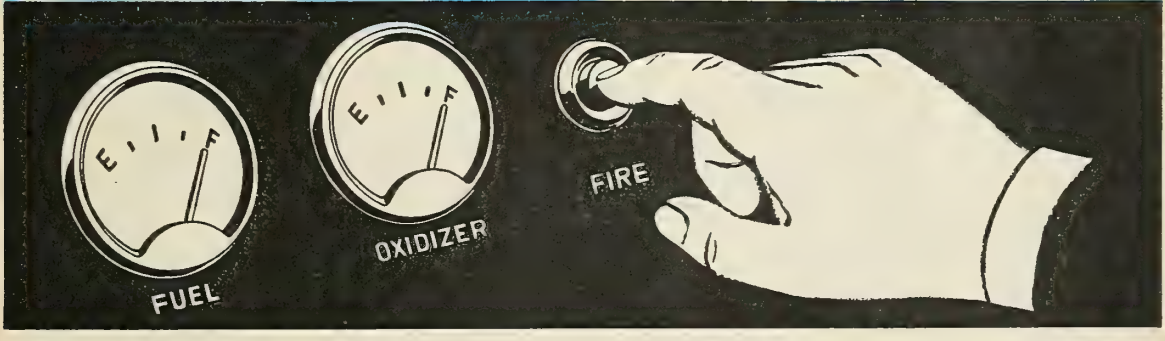
The helium test facility consists of five 2-cu. ft. cylinders manifolded together and capable of storage pressures up to 6,000 psig, 50 8½-cu. ft. cylinders similarly manifolded for storage up to 2,400 psig, and two 1,000-cu. ft. low-pressure receiver tanks for the collection of helium expended during testing.

There is also a vacuum and perlite insulated 500-gal. liquid nitrogen or liquid oxygen storage tank, plus essential piping, instrumentation, manifolding, safety valves, pressure regulation controls, vacuum protection, bleed valves and polution dampers.

The system can provide helium flows as high as 80 lbs./min. at pressures up to 6,000 psig and at temperatures ranging from —300°F to 165°F. Liquid nitrogen or oxygen, as required by special tests and for use in operating heat exchangers, can be supplied at flow rates up to 100 gal./min. at pressures as high as 100 psig.

All helium used for testing is recycled. It passes from test stations into the two large low-pressure storage tanks, from which it is drawn to be recompressed, dried, filtered and stored in the high-pressure storage tanks.

Recycling allows a significant saving in strategic gases. Absolute system cleanliness is maintained at all times.



Eldon Fiberglass Adds To Los Angeles Plant

Eldon Fiberglass Manufacturing Co. has added 40,000 sq. ft. of plant facilities to its Aircraft Division at Los Angeles. New plant is equipped for research, prototype work and volume production of fibreglass reinforced plastic parts for missiles and aircraft.

Simmonds

LIQUID LEVEL SENSING SYSTEMS can keep Rockets ready for INSTANT LAUNCHING

Before the "FIRE" signal is given, a rocket or missile stands ready on the launching platform, frequently for a considerable time. Yet it must be fueled and ready to fire at any time, in spite of the evaporation of the highly volatile fuel.

To keep fuel constantly up to capacity, Simmonds Liquid Level Sensing System senses when the fuel goes below a prescribed level. Automatically, the System then actuates a valve to add more fuel, shutting off when "full" level is reached. This process is continuous until the rocket is launched.

These Simmonds Systems have no moving parts—are shock, vibration and corrosion resistant—operate on low power consumption. They operate in any aircraft fuel, hydraulic fluid, jet engine oil and other liquids and liquefied gases, meeting all MIL specs. Detailed literature on request.

Outline of 1000 Temperature-Pressure Problems

Any rocket engine looks simple in silhouette—but its 150 or more parts present new and complex problems of operating temperatures and pressures. This is the reason why The M. W. Kellogg Company, leading designer and fabricator of industrial high temperature, high pressure vessels and steam power piping, was assigned a major role in the development and production of over ten different guided missiles to date, including the Terrier.

Steam power piping and rocket motors, for example, have much in common. In the latter, nozzle temperatures are around 5000 deg. F. and pressures 2000 psi. In steam-electric power plants, the Kellogg assignment concerns piping to withstand 1250 deg. F. and pressures over 5000 psi. Both problems include selection or development of not only the proper alloy to provide correct strength-weight relationship and resistance to corrosion or erosion, but also the welding techniques, materials, and skills to fabricate the alloy into large or intricate shapes.

M.W.Kellogg's long fabricating experience with high temperatures and pressures can be a valuable asset to all manufacturers concerned with the rocket program, and to those responsible for process equipment in the petroleum or petrochemical industries.

Fuels for the Atomic Rocket

by Alfred J. Zaehringer

TODAY'S VIEW of the atomic rocket—a pile to heat a working fluid—is beset by such bugaboos as heat transfer, high temperatures, and corrosion. These problems can be solved by technological breakthroughs or by a painstaking, empirical approach. It is certain however that developments now taking place in the atomic reactor field will form one of the ribs of any future atomic rocket.

Free world reserves of uranium oxide concentrate are estimated equivalent to ½ million tons (some 500-1,000 million tons of ore). This conservative estimate was recently made by the firm of Arthur D. Little, Inc. If one includes presently uneconomical uranium-containing shales and phosphates, the uranium reserve figure would increase. Based on 1958 military production rates, these known reserves will hold out for 25-50 years.

The U.S. now produces 3 million tons of ore each year and will increase it to 5-6 million tons by 1958. Most of this is slated for military purposes. It is estimated that our capacity for uranium will be ten years ahead of any civilian power requirement.

Propulsion

In the U.S., about 70% of our reactor work is devoted to propulsion, mainly aircraft and ships. By 1965 all new naval vessels will be nuclear-powered while the entire U.S. Navy will be nuclear by 1980. Commercial nuclear-powered aircraft will be started by this date according to Arthur D. Little, Inc.

Atomic Fuel

Replacement for chemical fuels is the atomic fuel element. The elements are mechanical structures made of a fissionable material (such as U-235). Atomic fuels are solid or liquid. Most reactors today use solid fuels. Because liquid fuels are more corrosive, much of the present reactor fuel research is with solids.

For the atomic rocket to beat the performance of a chemical rocket, atomic motors will have to operate at temperatures much higher than present 900-1,000 F power reactors. Right now, research is concerned with raising temperatures to 2,000-3,000 F in order to raise efficiencies. It is interesting to note that North American Aviation, Inc. hopes to raise reactor temperatures to over 3,500 F.

The uranium or thorium fuel elements (metallic or metal compounds)

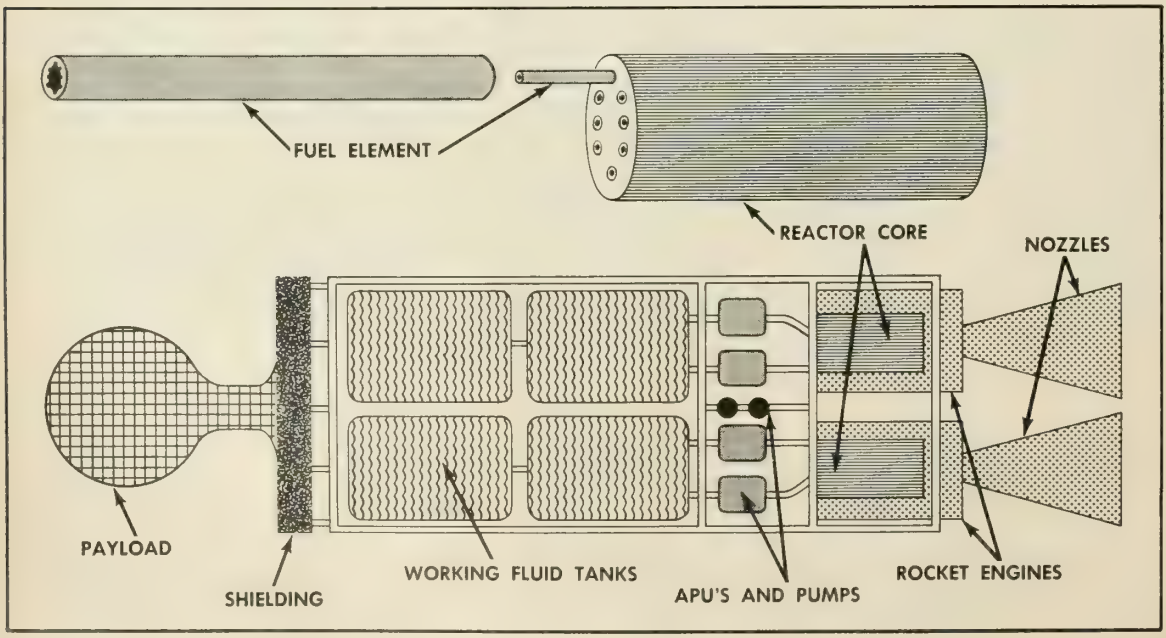
General Electric nuclear propulsion proposals as shown at recent Philadelphia atomic power exhibition. GE is one of the pioneers in this field.

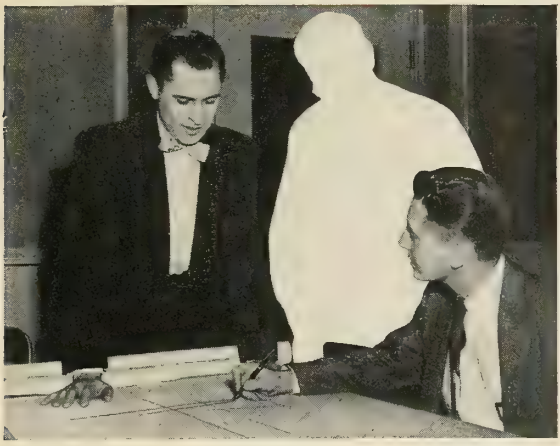
are clad with a wide variety of metals for corrosion protection. Metals include: aluminum, beryllium, chromium, columbium (niobium), copper, nickel, nickel-chromium, magnesium, molybdenum, silicon, stainless steel, titanium, or zirconium.



Mixtures of metals, ceramics, and even cermets are also being considered (see table). In considering semi- and non-metal materials, however, thermal shock is important.

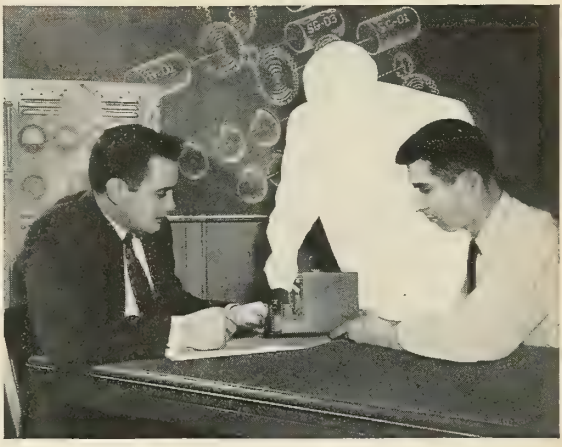
Fuel elements of the solid nuclear material may be in pellet, rod, or plate form and are of various hollow configurations. These configurations have to allow the proper heat transfer and also support a chain reaction. The geometry also has to allow for control of the reactor and for easy removal. The fuel has to be "canned" to prevent excessive loss of fission materials.

Present reactors have elements about 4-6 inches in diameter and 4-6 feet long. Several elements are assembled into a reactor core. Not only must the element and core have to stand the high temperatures and corrosion but radiation now lets only 1 per cent of nuclear fuel to be consumed before the element has to be yanked out and replaced. The reasons for this are structural damage by neutrons, and fuel poisoning.



Although the reactor problems associated with the atomic rocket now look like mountains, it is encouraging to note that developments now taking place in the power reactor field are gradually wearing down the mountain.

This growing technology that will aid the atomic rocket include: heat transfer, better high temperature materials and fuel elements, antidotes for fuel poisons, and better radiation-resisting materials. Thus, development of the atomic rocket can now take a free-ride on the rising materials and know-how curve of power reactors.★



The atomic rocket that may never be built. Although this principle is feasible—we might concentrate on electro-nuclear propulsion systems.

Where do you belong in IBM Military Products?

Systems Design Engineer: Before his recent promotion, this man formulated advanced concepts of configuration, capabilities, and operational features, and coordinated the design of radar, computer and inertial equipments for optimum integration as a system. Engineers interested in military systems, computers or servo applications will find opportunities in error analysis, ballistics, reliability, and electro-mechanical, servo and equipment interconnection design. *Could you handle his responsibilities?*

Test Equipment Engineer: Also promoted recently, this man formerly developed test sets of advanced design, requiring precision electronic measuring circuits and mechanisms meeting military specifications. He started with specification requirements and carried designs through model testing by electronic and mechanical engineers. This activity includes application of servo-mechanisms, packaging of precision components, and liaison with sub-contractors in many fields. *Could you handle his responsibilities?*

Challenging jobs are now open!

Organized only 22 months ago, IBM Military Products Division has grown enormously, opening up opportunities to engineers and scientists in all these fields:

- Circuit Development
- Components
- Cost Estimating
- Digital and Analog Systems
- Electronic Packaging
- Electronics
- Field Engineering
- Heat Transfer
- Human Engineering
- Inertial Guidance
- Installation
- Mathematics
- Mechanical Design
- Optics
- Physics
- Power Supplies
- Programming
- Reliability
- Servo-mechanisms
- Systems Planning and Analysis
- Technical Publications
- Test Equipment
- Transistors

At the new plant and laboratory in Owego, N. Y., IBM designs and manufactures advanced airborne analog and digital computers for Air Force bombing-navigational equipment. At the new Kingston, N. Y., facilities, IBM builds the world's largest electronic computers for Project SAGE, part of our nation's giant defense net.

The electronic computer field offers one of the best ground-floor career opportunities today. Economic experts rank the electronic computer in importance with automation and nucleonics in growth potential. Sales at IBM, the recognized leader in the field, have doubled, on the average, every five years since 1930. Engineering laboratory personnel quintupled in the past five years. Future expansion plans offer even better opportunities. As a member of IBM Military Products, you enjoy the stability and security of the IBM Corporation, plus the opportunity to progress in any other IBM division. Promotions open up frequently from continuous growth. The "small group" approach assures recognition of individual merit. Salaries are excellent and company benefits set standards for industry.

For the facts about an engineering career with IBM Military Products Division, please write to:

Nuclear Powered Rockets

and the Problems of Heat Release

by Rudolf H. Reichel
Bell Aircraft Corp.

UP TO THE PRESENT our rocket propulsion systems have been entirely dependent on chemical propellants, either in a liquid or solid state. Because of their heat content which results in a specific impulse in the order of 200 to 400 lb-sec/lb, high mass ratios have to be realized in order to fulfill a given mission. This means multi-stage rockets are necessary in many cases. To escape from the earth's gravitational field, or even to bring any payload in a satellite orbit, at least two or three-stage vehicles are required.

No basic change can be expected in the capability of chemical propellants even for liquid hydrogen or fluorine as components. Because the resulting high mass ratios severely restrict space flight, man is looking for higher energy propulsion systems.

A unique power source leading to basically new propulsion concepts has become available with the discovery of nuclear energy. Proposals have been made for example, to use free radicals to produce the reaction $2H \rightarrow H_2$, to heat up an inert working fluid, to produce photons or ions, or to use the nuclear energy of fission or fusion.

It is beyond the scope of this article to discuss which of these propulsion principles are or seem to be realistic. However, it is of great interest and importance to describe the critical factors which govern the application of these "super fuels."

First because of the tremendous heat content of nuclear fuels, e.g. U-235 or Pu-239 yield about 3×10^{10} BTU/lb, it is interesting to study the feasibility of any nuclear-powered rocket propulsion system. If it were not for the numerous technological and shielding problems, doubtlessly very favorable mass ratios would result.

However, this promising situation also has a major drawback. According to the momentum principle, the amount of energy which must be released in the combustion chamber or in the re-

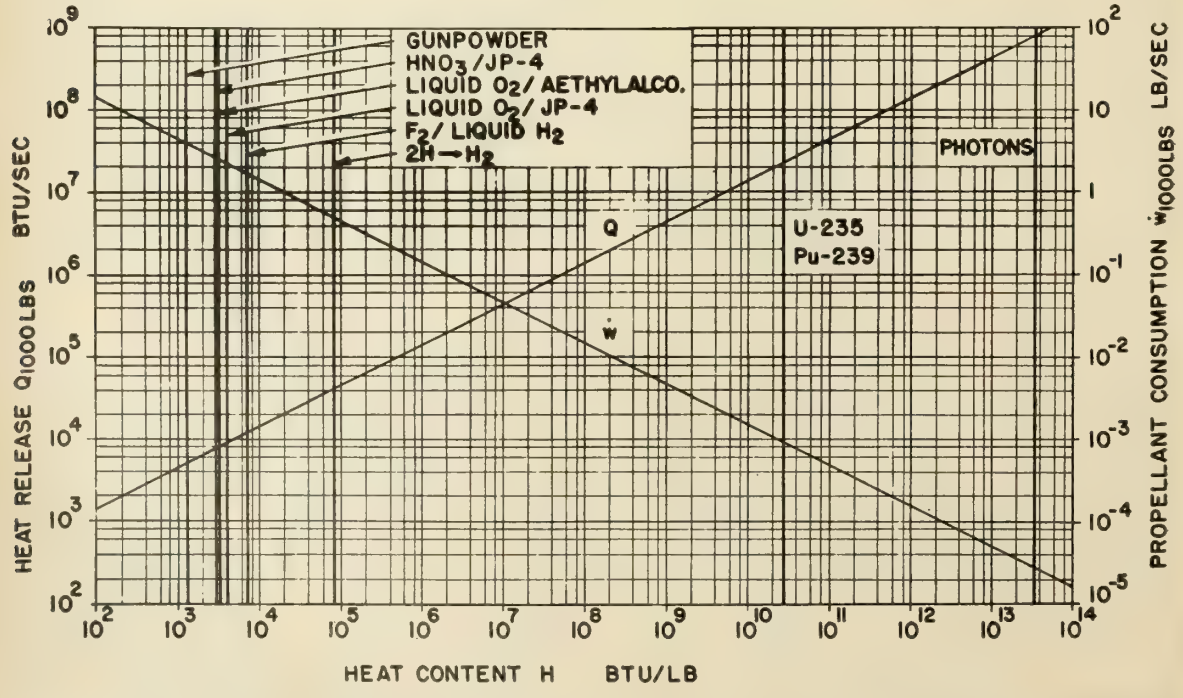

Figure 1 is a full log graph showing heat release Q and propellant consumption w for 1000-lb thrust versus heat content H for different propellants. Heat content of photons assumes the complete conversion of one pound of mass according to $E=mc^2$.

action section of the powerplant in order to generate thrust follows the simple functions of $(H/\eta_i)^{1/2}$ or c/η_i. H represents the heat content of the propellant, c exhaust velocity; η_i internal efficiency of the reaction process.

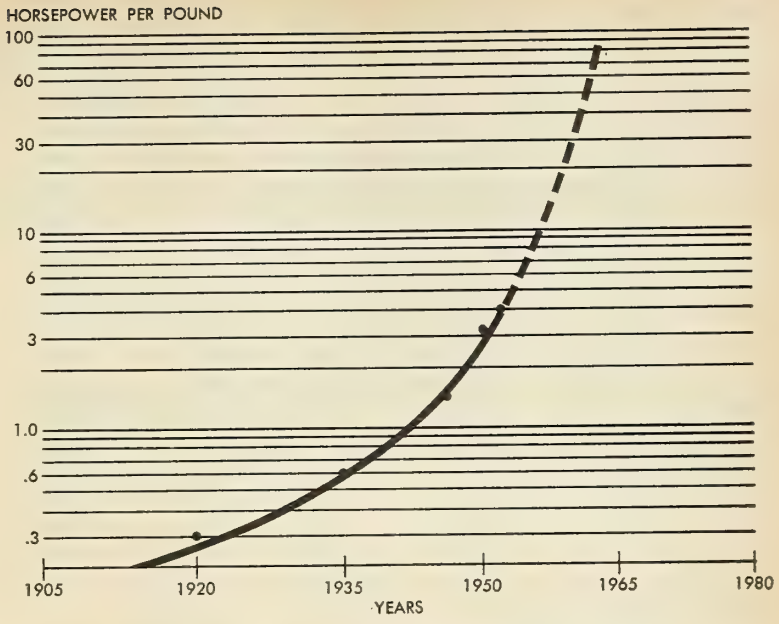
In Fig. 1 this relationship is presented by plotting the energy Q released for generation of 1000 lbs. of thrust versus the heat content H of some typical "propellants" when the internal efficiency is assumed to be 100 per cent. Moreover, the propellant consumption $\dot{\omega}$ shows that with increasing heat content it has a tendency to decrease as per the relation $(H\eta_i)^{-1/2}$.

For purposes of comparison a constant internal efficiency η_i is assumed. Heat must be released according to the ratio $(H_{II}/H_I)^{1/2}$ or c_{II}/c_I, where the subscripts I and II refer to the propellant contents with II higher than I.

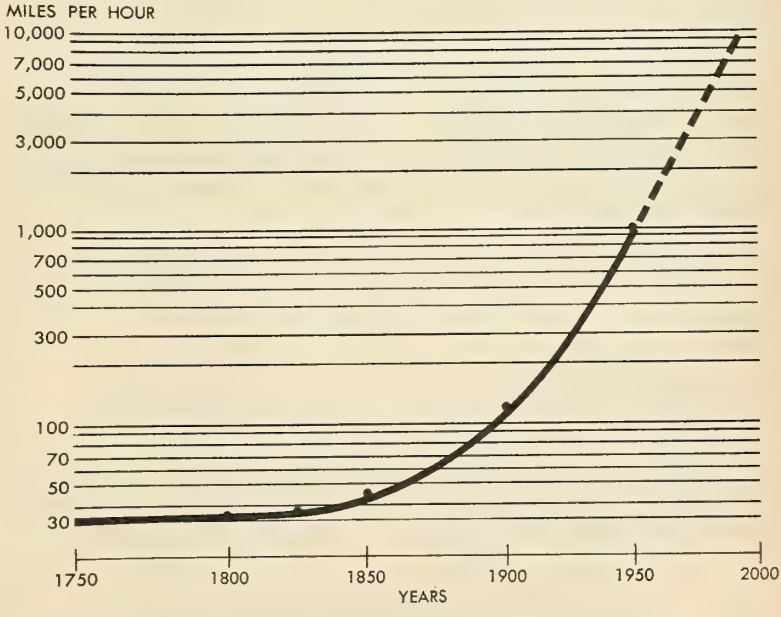
In a hypothetical rocket generating its thrust by fission of U-235, more than 2000 times the energy must be released than is required for an equal thrust motor using common chemical propellants, for comparable η_i. Even for a thermonuclear rocket using the reaction $2H \rightarrow H_2$, about five times the energy would be required compared with common chemical propellants.

In the application of the photonic rocket principle, which is still entirely hypothetical, a tremendous quantity of energy has to be released per unit thrust. About 100,000 times that of chemical propellants is necessary. The area of the photon reflector becomes very large and may become unrealistic in order to keep the surface temperature in a reasonable range.

The application of nuclear power for rocket propulsion obviously would provide tremendous energy quantities. From a pure performance point of view this would indicate great progress. However, the basic law of heat release shows that the quantity per unit thrust increases with increasing enthalpy.



This leads to problems which we currently do not know how to handle. It seems that entirely new techniques of heat transfer are needed in order to deal with energy release problems.

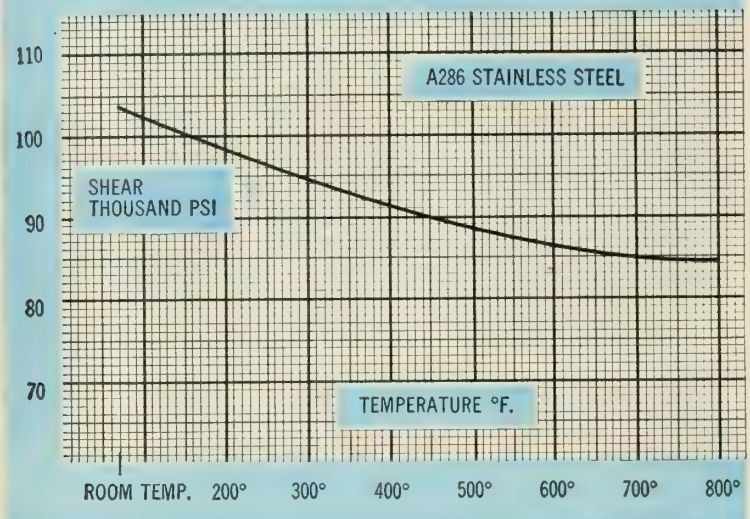


In this connection, the structural properties of materials at high temperatures form a critical factor. It would seem that any solution must probably entail the use of magnetic or electrical techniques now under study.

In addition, since at the temperatures involved virtually all particles of matter could be highly ionized, considerable additional knowledge of heat flow rates, flow characteristics and shock wave phenomena in ionized gases is needed.

Because of the high heat release when high performance propellants are applied, proposals have been made to avoid some of the problems by taking advantage of special applications, such as use beyond gravity.

In this case only a very small acceleration of the vehicle would be required. Therefore excessive reaction temperatures can be avoided and realistic reaction areas are adequate. In order to fulfill the above requirement, the ascent of the rocket from the earth must be achieved by the use of conventional propulsion. ★



These two half-log graphs provide a dramatic evidence of not only man's quest for greater and greater speed but of his success in achieving it as well. The top graph shows thrust-horsepower per pound of engine weight plotted against time. That below shows the advance of speed records against time. The remarkable point about both of these is that they curve upwards on a log plot. A straight line on a half-log plot is considered to be the normal learning curve. The accelerating rate of rise is evidence of the addition of creative thought to the normal learning process. The successful application of nuclear power to propulsion, directly or indirectly, will sharpen the curve more.

NOW, Cherry Rivet announces the

✓ HI-STRENGTH

Martin Tests Titanium For Hydrogen Content

Martin now regularly tests samples of its titanium for hydrogen content with a Vacuum Fusion Gas Analysis Apparatus developed by the National Research Corp. The apparatus could also be used to determine the amount of various basic elements in other metals.

During the various stages in the refinement of metals, small quantities of oxygen, hydrogen, carbon, and nitrogen are retained or picked up by the metal. Minute amounts of these impurities may produce marked effects upon the final properties of the metal. Good strength combinations are possible with these interstitial alloying elements—oxygen, hydrogen, carbon and nitrogen. However, other properties such as impact and notch-toughness suffer disproportionately.

GE Develops New Leak Detector

A newly-improved electronic leak detector "so sensitive it can detect one part of helium in two million parts of air" has been announced by General Electric's Instrument Department.

Based on an original development for the wartime Atomic Energy Program, the re-designed mass spectrometer leak detector features extreme sensitivity and fast response.

Ten times more sensitive than its predecessor, the new M-2 leak detector finds and locates leaks in vacuum or pressure systems. It is used by electronic industries, nuclear developments, and research laboratories for quality control and production checks.

AF Breaks Ground For ICBM Training Base

Ground has been broken for the first of several technical facilities to be constructed at the Air Force $100 million ballistic missile training base at Cooke Air Force Base, Calif.

Installation is slated to have several thousand military and civilian personnel by December 1958.

Aeronutronic Expands

Aeronutronic Systems, Inc., a Ford Motor Co. subsidiary, has added a 10,000-sq. ft. experimental shop to its Glendale, Calif., plant.

Crucible Steel Reports $1.5 Million Expansion

Crucible Steel Co. of America has announced a $1,500,000 expansion program for Vacuum Metals Corp., division of the company's Sanderson-Halcomb Works at Syracuse, N. Y.

The program, which will double the company's capacity for producing high-purity vacuum-melted materials, will include a vacuum induction furnace capable of producing 3,000-lb. ingots, a melt shop building to house the furnace and additional space for expansion, and a metallurgical-chemical laboratory building for production control and development.

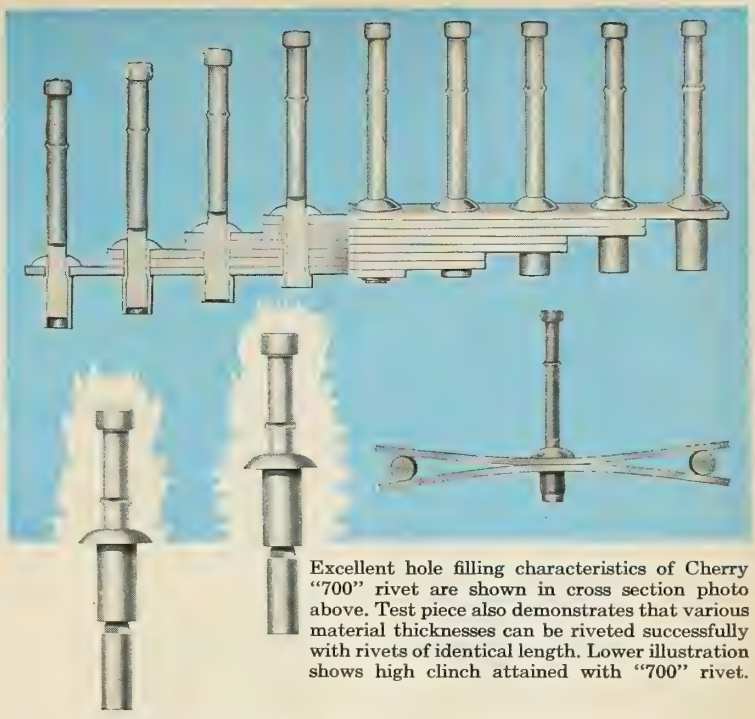
The expansion is being undertaken to meet increased demand for vacuum-melted high-quality bearing and high-temperature alloy steel.

Kaiser Aircraft Gets Contracts

New contracts calling for the production of more than $1,700,000 in guided missile testing equipment are being awarded the Electronics Division of Kaiser Aircraft & Electronics Corp., Toledo, Ohio.

Destined for use by the Air Force, the test equipment allows technicians to make automatic ground check of the operating characteristics of a missile before firing. The pre-flight "Go-No/Go" tester simulates functions of flight.

AF Awards $21 Million For *Navaho* Development



North American Aviation's Missile Development Division has received an additional $21 million for research and development work on SM-64 *Navaho* from the Air Force.

Navaho is currently undergoing tests at the Air Force Missile Test Center in Florida. Testing began after the flight program of the X-10 test missile was completed.

Northrop Employes Get 1 Cent Hourly Raise

Some 14,000 hourly-rated personnel at the Northrop and Anaheim divisions of Northrop Aircraft, Inc., received pay increases of 1¢ an hour effective April 29 as a result of an increase in the Consumer's Price Index.

Northrop's cost-of-living wage program is based on quarterly reviews of the price index. Personnel at the Hawthorne, Anaheim, El Segundo, Palmdale, Edwards Air Force Base, Pasadena, Torrance, Alamogordo, and Cocoa installations are affected. Northrop is producing the *Snark* missile.

Excellent hole filling characteristics of Cherry "700" rivet are shown in cross section photo above. Test piece also demonstrates that various material thicknesses can be riveted successfully with rivets of identical length. Lower illustration shows high clinch attained with "700" rivet.

CHERRY "700"* Aircraft Rivet
Gives More Effective Fastening

The "700" rivet is versatile and in many cases one length of each diameter will cover all thicknesses of material. Also, the sheet hole size is not critical as with other rivets since the design provides positive hole fill even in oversize holes. The stem always adjusts to fill the hole which affords high stem retention independent of hole size.

The manner in which the "700" rivet is set provides high clinch by drawing the sheets together tightly and uniformly. When the "700" rivet is set, the stem shoulder protrudes above the rivet head and gives visual indication that the blind upset is properly formed, the sheet hole is filled and the rivet is properly set.

*Patents issued and pending

The "700" rivet is available in countersunk and universal head styles in a wide range of diameters and lengths. It is installed with standard Cherry rivet guns with controlled-stroke pulling heads and accessories.

This fastener advancement is a typical example of how the Cherry Division has paced the industry with new and improved fasteners and the tools and accessories for applying them—all of which are designed, developed and produced in the Santa Ana plant.

For technical data on how the Cherry "700" rivet will give you a more uniform method of fastening, write to Townsend Company, Cherry Rivet Division, P.O. Box 2157-Z, Santa Ana, California.

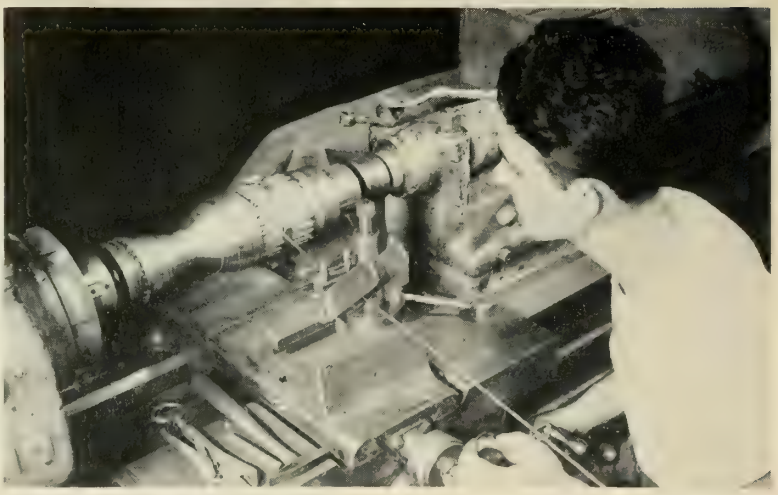
Missile Arming Solenoid tested at 115,000 ft.

A new arming solenoid, qualified to MIL specifications has been tested at altitudes to 115,000 ft. Designed specifically for arming of a missile on a very high performance fighter, the solenoid can be adapted to other applications. The compact unit weighs only 11 oz., has a normal power drain of 0.7 amps and operates at down to 18 volts. At −65° F and 29 vdc power drain is only 1 amp. Operating temperature range is +250° to −65° F.



While specifications required testing to a lesser altitude, the solenoid was tested at 100,000′ and 115,000′. At 100,000′ altitude 700 RMS 60 cycle current was applied between winding and case for more than a minute. There was no corona discharge, arcing or shorting. At 115,000 feet the test was repeated with voltage being increased at a rate of 25 volts/second. At 825 volts a corona appeared suddenly. Apparently based on electron emission there was no sharply defined path of high conductance. Subsequent retesting of the identical unit showed no damage resulted from the 115,000′ test.

For further information on this high altitude solenoid write to:

NACA Studies New Fabrication Methods

NACA 5000 lb. thrust rocket chamber in NACA sheet metal shop at Lewis Flight Propulsion Lab. This rocket chamber is wire-wrapped and then braced to provide extra structural strength.

Spun chamber with outer channels for fuel flow control. Left, casing. Right, throat.

Chambers left to right: Spun, finished, corrugated, hydraulically or cast formed, chamber with flow directors braced on and outer casing suitable for any type rocket chamber. Further information is available by contacting NACA and requesting NACA Technical Note 3827.

Aerophysics

By Seabrook Hull

A nose cone that melts or burns but remains lethal to the point of detonation continues to be the only feasible solution to the medium-to-long-range ballistic missiles. The same temperature-materials restrictions that put a known top limit on the efficiency of conventional liquid, solid and (soon) jellied chemical rockets also restricts nose cone design. There is not and may never be a material that will permit the design of a non-deteriorating warhead for IRBM's and ICBM's.

Post-World War II research into high temperature materials has shown that none remain solid beyond about 3500°C. This is a function not of man's ingenuity in devising new molecular combinations (which would give hope of a major breakthrough someday) but of the bonding forces of one atom for another. It is a matter of basic physics, not chemistry. The practical limit for the structural use of any material is 3000-3200°.

It is conceivable that the space ship of the distant future, making a fast reentry, may employ intense magnetic fields to shape ionized and dissociated gases into heat shields for its nose. But it is not practical to consider for the "ultimate" weapons of today.

W. R. Warren, General Electric's Missiles and Ordnance Systems Department, in a paper, Hypersonic Experimentation, indicates the ball-park conditions surrounding reentry: "For typical values, if the flight Mach number is 16 and the altitude is 100,000 feet the temperatures immediately behind the shock front and at equilibrium are approximately 15,000°K and 6000°K, respectively."

Since materials cannot be looked to for the final answer in nose cone stability during reentry, aerodynamic design to minimize heat transfer is of prime importance. Recently devices for studying hypersonic flow and heat transfer have increased both in number and utility. These include the wind tunnel, shock tube, shock tunnel, plasma jet, shaped charged accelerator, rocket exhaust, solar furnace and the hypervelocity mass accelerator. This last, by timed electrical discharges into helium gas behind a piston holding the model, is capable of uniform acceleration to 60,000 ft/sec.

And for possible hypersonic flight application, two new materials: a crystalline material made from glass, now in the pilot production stage; and a ductile ceramic in the laboratory stage.

Pyroceram, a family of "extremely hard, fine-grained crystalline materials formed from special glasses," has just been announced by the Corning Glass Works as having "good mechanical strength, excellent electrical insulating properties at very high frequencies, high deformation temperatures, superior thermal shock resistance, and hardness." They are susceptible to conventional forming methods.

Under an AF Office of Scientific Research contract, E. R. Parker, J. A. Pask and J. Washburn at the University of California have produced in the laboratory single crystals of magnesium oxide (melting point, 5072°F) that are ductile. This was done by special surface treatment. While theoretically these crystals could be grown to any size and machined to desired shapes, work is accelerating on inducement of ductility into polycrystal structures.

Even a good BS in EE may not know our "baby" . . .

NUMERICAL CONTROL

You have your BS in ELECTRICAL ENGINEERING, and maybe a year or three of experience in things like:

- industrial electronics
- servomechanisms
- digital or logical circuits
- transistors

NUMERICAL CONTROL is a new area for progress in electrical-electronics activity. Our expansion in it calls for a few men who are above average in ability. We are too compact to afford the dubious luxury of a second team. If you have the sheepskin and possibly some experience (and if you are going to be a TOP man), you'll answer this ad.

Tell us who you are, what you have done, what you want to do. We will, in return, tell you about our plans.

Engineering Beyond the Expected...

DESIGN beyond the expected
The DOVAP prototype (above) is one half the size called for in specifications.

PACKAGING beyond the expected
Shielding of critical areas and equalizing of heat enabled DOVAP to operate at higher temperatures than specified... without benefit of cooling by either conduction or convection.

PERFORMANCE beyond the expected
Where momentary loss of signal means the end of usefulness, DOVAP functioned unfailingly... under environmental conditions of shock and vibration more severe than specified.

ASSIGNMENT MISSILE

Withstanding torture is a specialty of Packard Bell's Doppler Velocity and Position indicator (DOVAP), designed and developed for an inter-continental missile (classified). In prototype environmental tests, this high powered Doppler Transponder was subjected to temperature, shock and vibration beyond the extremes expected in flight... beyond the extremes called for in specifications.

RESULT: Reliable signal and continuous transmission for an incredible life span.

Write for new Packard Bell Electronics facility brochure... just off the press.

Spaceman Col. Bill Davis

Details Absolute Limits of Chemical Rockets
Suggests Magnetic Ramjet for Orbit and Escape
Emphasizes Need for More Relativity Studies

Colonel Wm. O. Davis, USAF, is Deputy Commander, Operations, Air Force Office of Scientific Research (ARDC). He's also a senior pilot having ended up World War II as a B-24 squadron commander—a member of Phi Beta Kappa and Sigma Xi and holds a Ph.D. in Nuclear Physics. But perhaps his greatest contribution to the future and security of the nation is that he has gathered a group of men under him who are not only willing to tackle the impossible but will try a new approach to it as well. Great scientific achievement never derived from wearing blinders.

Q. *Col. Davis, can you give us some idea of the future of propulsion, the practical limits on rockets, for example, and what comes after?*

A. The basic problem is fairly straightforward. Right now, all propulsion systems have one thing in common: They're heat engines. Heat, by definition is a random process, and when I heat a gas, whether to push a piston with it or to simply squirt it out the back end, basically I have one serious problem: My energy is going in all directions. A large percentage goes into the structure as heat.

This leads right to the fact that you are limited by materials. I don't know exactly what is the best material we've got now, but for sustained operations it's probably good to somewhere in the neighborhood of 1500° to 2000° centigrade. In the course of time we may be able to double that—up to about 3000° C.

Q. *What kind of material would that be?*

A. Probably magnesium oxide or something like that. Carbon goes to about 3200° C. Above 3500° C any material is in a gaseous state. You're not going to make an alloy or a ceramic or anything else out of gas. This is the end of the line. There isn't ever going to be a 10,000° C material, unless you actually learn how to modify an atom.

Q. *Where does that leave us?*

A. Well, if you double the temperature at which a solid or liquid rocket—any rocket based on heating a gas—can operate, by the equations of rocketry, you only increase your exhaust velocity by the square root of two. In other words a 40% increase in specific impulse is all that can possibly be expected, no matter how good the propellant is. It makes no difference whether I do this with ordinary chemical fuels, free radicals, nuclear piles or any other source. Where I heat and expand the gas through a nozzle in the way a rocket does. I'm limited to a 40% increase.

Q. *40% over what?*

A. Over what we now have in the way of a rocket.

Q. *Is it practical to think of putting a man in space at this time?*

A. Yes, for certain types of objective. For example, to pinpoint the location of, say, a satellite, if you rely on transmitting from the earth to the satellite, your uncertainty of where it is is quite large and at the distance of the moon or anything farther, your knowledge of its location is very poor indeed. You're faced with the fact that you're going to have to transmit and observe from the vehicle.

It may turn out, surprisingly enough, to be somewhat easier to do this with a man. Problems of communication, navigation, maneuver and return to base—for that matter, the interpretation of information—may be made an awful lot easier with a man than it will be to design automatic equipment to do it.

Q. *How would you put a man in space?*

A. The limiting factor of just about 40% more exhaust velocity is ultimately going to prevent you from using a heat engine. It will be neither safe nor economical. All right, what other properties do I have to work with? Electricity and magnetism are a possible approach.

With an electric or magnetic field I can make my particles go in a straight line, rather than just heating them up in a random way so that they push against the walls of the chamber in all directions and heat it up. Electrically or magnetically I can make them go in just the direction I want. I can use all the energy I've got effectively.

Q. *Won't this concept almost invariably require a conventional rocket booster in order to build up initial escape velocity?*

A. No. This is another thing that bothers me. People are under the illusion that the only way to get off the surface of the earth is with a straight up, 10 *g* blast off, or something of the sort. This goes back to a concept that was laid down and developed in about 1924.

I would start with an air-breathing engine, either an ordinary turbojet or a ramjet or a combination of both.

What I want to buy first of all is altitude, and I want to use a propulsion system which is most efficient for that purpose. Secondly, having gotten altitude, and not before, I want to buy speed. Speed at sea level costs too much. I wait until I'm up 150,000 feet or so; then I buy my speed.

Q. *Can you attain escape speed in a ramjet?*

A. Not necessarily with an ordinary ramjet by itself, though I could get some pretty high speeds, perhaps Mach 5 or 10. There I have reached maybe 150 miles altitude where most of the air particles present are charged.

Q. *Would you then cut in your ion propulsion system as a kind of boost to the ramjet?*

A. Yes. As I reach this region where I have charged particles available I will begin to apply part of my total energy magnetically. I'll just begin to. Then, as I go higher, I'll get an ever increasing portion of my thrust magnetically,

until I reach an altitude where the thermal aspects of a ramjet won't be effective. By this time virtually all the gas is ionized—multiply ionized. Now I'm going much faster, so that the total volume of gas going through that I can act on is getting greater.

Q. *Well, using the ionized air at altitude in this way, don't you end up with a kind of magnetic ramjet?*

A. Yes. I don't know whether what anybody has in mind right now is practical or impractical, but I'm convinced that one way or another we're going to find out how to use electricity or magnetism for thrust. And, I think the logical way to do it is magnetically. If I use my energy to create a magnetic field that works against a charged gas, I can probably get orbital velocity within the atmosphere—at an altitude somewhat below 500,000 feet and just coast off into an orbit.

Q. *Now you've set yourself a kind of linear accelerator out in space. What's your power source?*

A. I have to carry it. This is where the true value of nuclear power really begins to be felt—as a source of energy. I can carry it with me and run it indefinitely.

Q. *Though space is popularly thought to be "empty," we understand there are charged particles out there. Is there any clue as to whether there are enough so that at very high velocities we can use them to effectively supplement the working fluid?*

A. According to Professor Fritz Zwicki of Cal Tech, yes. These particles would be very highly charged—many times ionized and probably stripped of all their electrons. He says that if you get going fast enough, you can scoop in enough of these things to where you get thrust out of them.

Q. *Would your working fluid be hydrogen?*

A. It depends on the velocity I get. I think that you would find that your working fluid would vary with the size of your vehicle and how far you wanted to go. Say I have the capability to accelerate my working fluid to a tenth the velocity of light. As soon as I get into this ballpark of exhaust velocities I have to worry about Relativity.

I've got to remember that what I'm after is not exhaust velocity which works fine at the lower exhaust speeds. I'm after momentum transfer. In other words as I begin to try to make the exhaust go faster, and I get it fast enough to where Relativity enters in, instead of making it go faster, I'm merely making it heavier.

Q. *Under the principle of conservation of energy, won't your momentum continue to increase proportional to the energy fed into the system whether it does so because velocity goes up or because mass goes up? Momentum is simply mass times velocity, isn't it?*

A. Actually momentum is mass times velocity only at relatively low speeds. The theory of Relativity defines momentum as $P=m_o v/\sqrt{1-v^2/c^2}$. Thus when v, velocity is small with respect to c, the speed of light, the equation reduces to simply the product of the mass and the velocity. However, when, v equals c, the momentum becomes infinite. However, in answer to your question the momentum will continue to increase proportional to the energy fed into the system but not in the same way it does at low speeds.

Q. *On this business of Relativity, as we start thinking seriously in terms of space flight and the velocities it implies, doesn't Relativity begin to become not a theory for possible application to basic research but a matter of practical, operational consideration. For example, according to Relativity the only limit on a space vehicle's velocity is its own observation of the speed of light. Yet this is constant at 186,000 miles per second no matter how fast the vehicle goes. On this basis, is there any limit to how fast man will be able to go in space?*

A. Well, once you leave the earth, you will still exist in a frame of reference—the solar system, the galaxy or something.

Q. *Suppose you close yourself in and refuse to consider any frame of reference but your own—just calculate your acceleration on the basis of classical mechanics?*

A. Under these conditions you will observe a constant acceleration but since your measurement of time is changing with respect to the earth it works out to give the same answer. In other words I appear to have a constant acceleration in my frame of reference but since my measurement of time is changing with respect to the earth, my earth-measured acceleration appears to decrease.

Q. *What I'm wondering about is whether or not there aren't too many scientists who tend to accept Einstein's theories as the last word?*

A. Einstein himself said many times that there was no doubt in his mind that as time passed on his theory would be shown by somebody to be merely a special case of a more general theory. I don't think he ever had any feeling of an immortal theory, but a lot of people do and this is understandable—It's what they learned at school.

Q. *This proposal to send a small rocket around the moon—Is it practical to consider it at this time?*

A. Let's put it this way: We have the technical capability to do it.

Q. *In the case of so-called anti-gravity, what is the actual research and development situation there?*

A. First of all, there is a very great deal of misunderstanding of the whole question of gravity. We are very much concerned with its study. The Air Force works in the gravitational field at all times. Anti-gravity or what-have-you might possibly someday result from such studies. However, there's an illusion as to what you would buy with so-called anti-gravity.

. . . a 40% increase in specific impulse is all.

It may be easier . . . to put a man in space.

What I want to buy first is altitude . . .

One feeling is that all you've got to do is paint anti-gravity on the bottom of something and immediately you rise to the moon. But this is phoney, because nobody has ever suggested we're going to do away with the conservation of energy, and if I'm going to lift a pound 100,000 feet, I'm going to expend 100,000 foot-pounds to do it. I'm going to have to supply exactly as much energy to do it with the gravitational field as I'm going to have to apply to do it with a rocket.

There's no way I can get away from it. The only advantage I might gain is a more efficient use of energy. Clearly if I have a nuclear source, I can generate electricity or what-have-you. If I could now apply this to direct interaction with the gravitational field, presumably I could rise more efficiently. The mere fact that I can control the gravitational field won't mean that I can get something for free.

Q. *But you do have conditions where you do, in effect, get something for nothing. The crystal radio set is an example. True, energy is expended and it had to be produced somewhere, but you as the user of the receiver don't have to supply it. Might it not be theoretically possible for a vehicle in flight to get part of its energy elsewhere in a similar manner?*

A. Well, this is perfectly true, and I'm not ruling out that you can't do something useful with the gravitational field. Certainly when we progressed to the point where we could generate an electro-magnetic field, we could do a lot more than we could with a lodestone.

In particular there's one neat little trick that has always appealed to me. Whether mass is positive or negative, it still goes to infinity at the velocity of light. In the Special Relativity equations, on the other hand, if my mass is zero the equation becomes interderminent.

Suppose I could so shield my entire vehicle from gravitational influences that to an outside field its mass seemed to be zero. Under these conditions, it appears, I would have no velocity limitations. It would be a very nice thing to do, but it's not the answer to all problems.

Q. *The Air force has some contracts out now for studying ion and photon propulsion systems, doesn't it?*

A. Nothing on photon propulsion, but we have several people working on various aspects of ion propulsion. What we're trying to do now is not to build a rocket but to study the properties of electrically charged gases at very high densities—how to handle them; how to accelerate them; how efficient is the process; what are some of the problems. This can be done in the laboratory, and done rather cheaply. The plasma jet is very useful.

Q. *Is this the same plasma jet they use for nose cone testing?*

A. Yes. Such a jet can be used for a lot of things. This is a nice way of producing about 20,000 degrees Fahrenheit for cutting very high temperature materials or for melting materials that can't be melted any other way. You can also use the same plasma jet to do experiments on ion acceleration and on the control of large bodies of ionized gas at high densities.

Q. *When you try to accelerate a plasma flow either electrostatically or magnetically don't you have a problem with mixed negative and positive ions?*

A. Yes. Admittedly you're accelerating one group of particles in one direction and one in the other, but in general your positively charge particles are carrying most of your mass. So while you balance your charge, your momentum has to be conserved. It is not a complex problem to collect your negative charges, which are mostly electrons and simply reroute them so you exhaust them in the same direction as the rest of your flow.

Q. *What about electrostatic control and acceleration of your ions?*

A. We're not particularly enthusiastic about the classical approach to ion propulsion, which is simply electrostatic, where you have a large potential difference, and you accelerate particles along this potential difference. Reason is that as you begin to get a lot of current in your ion jet. It becomes an almost perfect conductor.

It's nearly impossible to maintain your potential difference. Furthermore, even if you could, at these very high voltages there's a tendency to start collecting electrons around the terminal. The space charge would defeat you. In other words, you'd eventually be pulling your exhaust gases back into you.

Q. *With excessive voltages wouldn't you also generate some very high intensity X-rays?*

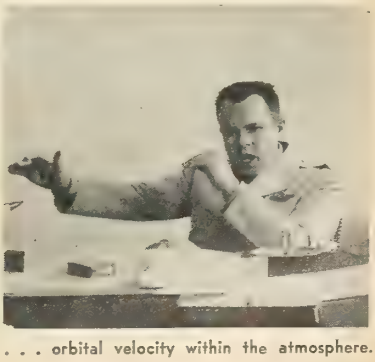
A. You very well might. Thus magnetic acceleration looks a very great deal more promising because you get high energies, but you stay away from high voltages.

Q. *How do you think development along this line will progress time-wise?*

A. Assuming you begin to get a pretty good feel for how you best go about accelerating charged gases, one of the next things you might want to do would be to stick something on somebody else's rocket and see whether you get any positive thrust, and if so, how much.

Q. *What is your objection to photon propulsion?*

A. I'm not terrifically excited about it because basically you still come back to the fact that it's a heat engine. You can't charge a photon and accelerate it magnetically. There's the same old problem of materials limits.



Q. *Do you think you'll run out of developmental potential in the chemical rocket, considering problems of lead time, etc., in, say, ten years?*

Then, not before, I want to buy speed . . .

Electricity . . . a possible approach.

. . . orbital velocity within the atmosphere.

A. We're going to run out in a lot less time than that, you see, because just the trend curves themselves show you that in all probability you're going to want what comes after much sooner than most people realize.

Q. *Conceivably then, you will have ion propulsion weapons systems working well before the 1970's.*

A. Well, if the principle is sound. The whole thing that confuses people is the length of time it takes to engineer something versus the length of time it takes to have a new idea. Suppose in 1938 I had decided that I wanted to drop charges consisting of 20,000 tons of TNT: I could have spent the next 50 years trying to develop an aeroplane to carry it. But a simple new concept gives me the capability to accomplish that particular job in much less time.

Q. *Can you indicate moneywise how much effort is being put into ion propulsion?*

A. It is very small. And even the effort going into ion propulsion, since we are a research organization, is not necessarily related solely to ion propulsion. The work with plasma jets can be useful in many ways. You want to find out its properties. You don't say this percentage of our program goes for ion propulsion. For example, the earliest work in magneto-hydrodynamics now contributes to this knowhow.

Q. *Magneto-hydrodynamics—what's that?*

A. A fluid which consists of charged particles behaves differently from an ordinary fluid because as each particle moves it generates its own little magnetic field, which in turn causes motion on the part of an adjacent particle which is also charged and also generates a field. You not only have a damping effect but an entirely different method of transmission.

For example, a magneto-hydrodynamic shock wave will transmit itself in an entirely different manner from a normal shock wave. This field of study had its origin in astrophysics. So, would you say research into magneto-hydrodynamics was part of your astrophysics or part of your ion propulsion budget?

Q. *By when do you think there will be an operational requirement for an ion propulsion system?*

A. Let's face it. There never has been a new concept developed because of a requirement. Somebody discovers something new, and then says what can I do with it. I will say this, however. If at some future time—and this might be two years from now if we're lucky and everything we've got under way proves to be fabulously successful; or it might be five, ten or fifteen years from now—we are suddenly in a position to say: Look, here is a new propulsion concept, and it's been demonstrated in the laboratory; it will work and it will give you the following capability. When this happens, in a very short period of time somebody will have established a military requirement for it.

Q. *When do you think we'll leave the heat engine? When will the next hike in speed and altitude, the step into space, require that we have something else?*

A. There's always an intrinsic military requirement to do the next thing. It would be nice and convenient if this weren't so, but its the nature of the beast. As soon as you think you understand a military environment fairly well, the enemy outflanks you, and this is a strategic war we're fighting.

This business of scientific research may seem quite far from the battlefield, but actually, we're at war now. People who fly airplanes and drop bombs are preparing for it. In the laboratory, we're at it. We're at war.

We have entered space or certainly are about to with military vehicles. It is becoming the next major military environment. There is an intrinsic necessity that we understand this new environment and that we understand it first and that we understand it best. Every other military environment that's ever existed always had the same start.

We can't sit around and wait until the last minute. This is too expensive. We're going to have to evolve a new military concept before the fact. So, in this sense there already exists a military requirement for a non-thermal propulsion system. It's not a formal one, but in the sense that it's related to future progress it exists.

Q. *What's the commercial application, if any, of such things as ion propulsion?*

A. Well, consider the problem of going faster and further, whether it's for military or commercial purposes. A very large percentage of the total energy you're using, whether it be in the gasoline engine of the DC-7 or what-have-you does nothing else but overcome drag. And the faster you go the higher drag gets.

It is inherently cheaper when I want to travel great distances, and particularly if I want to do it fast, to go high first and then go fast, rather than try to beat my brains out against an atmospheric wall. These propulsion considerations are not entirely related to just some future far-off time when we're going to be fighting a war in space, they're related to the national economy. We're consuming our natural resources at a tremendous clip. How much can we afford to throw away?

Q. *Who gives the go ahead to start building towards a space force?*

A. It is not our job to decide whether the United States is going to build a space force. Somebody at some future time, and it may not be too far away, is going to have to face a decision at a very high level. Somebody is going to have to take note of the fact that the Soviet Union is heavily in the business of astronautics.

Somebody is going to have to decide if it is or is not worthwhile from a military point of view to push such a program. Now, we don't make that decision, but on the other hand you can't make it in the absence of facts. You first have to know what is the real capability. How much will it cost? What are the problems? How much of the national economy is going to have to be diverted?

Q. *Do you find it hard to get support for this kind of research?*

A. Within the last few years our top management has shown a very, very enlightened attitude. It's been quite remarkable that people have been able to understand this type of research. We've gotten excellent support out of the Air Staff and out of General Power in ARDC; also from the Assistant Secretary for Research and Development. We've gotten excellent support from every level.

Q. *You're primarily a basic research organization?*

A. Yes, but we do have a philosophy of management here which says that we believe we have to do more than just support basic research. If all we do is support it, we might as well turn our money over to somebody else and let them do it, but because of the fact that we are supporting basic research, we have a magnificent input of information in every field of science, and therefore with a very small group of people, we're in a position to try to synthesize results coming in from every field.

Q. *This provides you with an excellent opportunity, but doesn't it also require that you and your staff maintain completely free and open minds?*

A. Yes, and we have fought for this for a long time. This is not a casual accident. It's taken a great deal of effort on the part of a lot of people to develop and maintain this opportunity to work in the particular way that we do. ★

From Redstone to Jupiter

Army Philosophy in Development of Ballistic Missiles

by Dr. Wernher von Braun
Army Ballistic Missile Agency

THE BASIC CONCEPT behind the *Jupiter* development is that it is the natural and logical next step after development of the *Redstone* missile. The well-tested and successful *Redstone* became a natural test-bed for guidance and other components of the *Jupiter*. *Jupiter* components of all kinds have been test-flown in modified *Redstone* missiles.

We have conducted captive runs with complete *Jupiter* configuration on the test stand, and obtained an average of several hundred different measurements per run. These furnished information ranging from powerplant performance to intimate environmental data such as the vibration pattern on a certain spot in the missile where sensitive equipment will be mounted. Such captive test information, in addition to *Redstone* flight test results, leaves very little to chance.

This wealth of test stand in-flight experience, coupled with the methodical testing and evaluation of all components, enables us to feel quite confident about the forthcoming flight-testing of the *Jupiter* missile itself.

The Army has pursued a minimum-risk program in the development of the *Redstone* and *Jupiter* ballistic missiles which provides optimum development and performance.

Basically it provides for the thorough testing of every component and minor and major assemblies, prior to launching of the missile.

There is a tremendous difference between delivering a block of research and development missiles to the proving ground, and firing them successfully on schedule. The former is essentially a question of shop capacity. The latter depends on the capability of the engineering team to evaluate flight results correctly and rapidly, make necessary changes, and furnish the modified missiles with a sufficient degree of reliability to the firing crew.

This development cycle—discrepancies uncovered in flight tests leading to modifications of further test missiles which are half-completed on the assembly line—is quite slow, thus it is difficult for even the most closely integrated team to keep the experimental missiles firing at frequent intervals.

The Army's *Redstone* and *Jupiter* missile programs are being handled by a closely-knit and tightly integrated team with many years of experience in the ballistic missile field. This team consists of experienced scientists and engineers of virtually every field involved in this relatively new art. It includes rocket engine men, structural engineers, physicists, aerodynamicists, gyro experts, electrical network specialists, as well as test stand engineers, tool designers and fabrication experts.

Such an integrated team is more than just a group of specialists working on the same premises. It is comprised of men who have what I call "practical systems experience," men who are familiar with the intimate functional cross-relationship of guided missile components, who know how an observed deficiency in their area of responsibility may affect an entirely

A production ballistic missile, REDSTONE is being weaponized for issue to field forces.

REDSTONE being hoisted into firing position.

different part of the missile. We thus have within the organization our own systems engineering group.

The need for utmost flexibility during the research and development firing period governs our design philosophy. We expect occasional surprises and setbacks, and the resulting need for modifications between test firings.

We do not believe it is wise to plan too high a rate of initial firings, nor to release too large a number of untested missiles to the production shops for the early flight testing phase.

We believe that by setting early production aims too high there is a very real danger of "drowning in one's own hardware." Too much hardware too early will tie up the bulk of shop manpower with the modification of half-completed missiles which failed their flight tests.

Our schedule called for a limited number of development missiles in the early phase, but for elaborate instrumentation and a maximum of telemetering. An extended inspection period, supported by comprehensive check and recording equipment, permits flight simulation for every missile and virtually all components.

We static-fire our missiles prior to final inspection and shipment to the firing site. This allows us to call freely on the design and development engineers for correction of any defects encountered. It also minimizes the strain on the proving ground facilities.

The proper places for shakedown testing of large ballistic missiles are the static test stand, the electronic simulator, the structural and mechanical test laboratories, and the environmental laboratory. Large missiles are too costly and too dangerous to be flight tested until every key man in the development is honestly convinced that he has exhausted every ground method of uncovering any deficiency.

Early development vehicles should be designed to use readily available and economical materials and construction processes, with final product engineering proceeding as a certain volume of experience is accumulated.

All the guided missile experience to date, including that on the *Corporal*, the *Nike*, and the *Redstone* indicates that this procedure is an effective and economical one for guided missiles. This becomes readily evident by comparison of preliminary layout and the final, operational product of any of these missile systems.

Close liaison is maintained with the production prime contractor during all stages of development. Thus production can begin almost immediately at any stage of the design.★

Chemical Aspects of High-Energy Solid Propellants

By Alfred J. Zaehringer

VIRTUALLY ALL modern solid propellants can be considered in the high-energy class. The performance range is from a specific impulse of 180-225 sec. The average Isp is probably at the 200 sec mark. This corresponds to a heat of combustion of about 1.0 kcal/g for typical systems.

During the past ten years the performance has increased some 40-50 sec. However, during the next ten years, we will be doing well to drain an additional 25-30 sec. The probable practical limit for conventional solids will be under 300 sec.

The reason: we are running out of good, *stable* chemical systems which can yield enough energy. In addition, such important factors as physicals, ease in processing, and cost are becoming increasingly important.

In essence we now have two types of solid systems. One, homogeneous propellants, have oxidant and fuel (reductant) combined in one molecule or mixture of molecules. Binding is largely a result of the chemical bond.

The other approach has attempted to strengthen the bond by use of plastic fuel-binders. Here, in heterogeneous (or composite) propellants, we have a separate oxidant compound bound together with a plastic adhesive which also serves as fuel. Fig. 1 schematically outlines processing techniques for both classes of propellants.

In general, the properties of the mixed propellant will determine how the grain is to be formed. For very stiff mixes, hot or cold milling may be required. Extrusion can be used with solvent systems or heavy composites. The general aim now is to arrive at castable mixtures, viz., mixes which can be poured (like concrete).

Techniques used in making castable propellants are exactly the same as for making concrete. In all modern systems, then, we no longer have "powder" rockets. Although powders may be used, the finished propellant derives its "solidness" from chemical bonds rather than from mere mechanical bonds. Thus, literally, modern solid propellants are really solid.

The first breakthrough beyond the ancient black powder came with the discovery of nitrocellulose around 1830. Nitrocellulose (cellulose nitrate is the more correct chemical name) combines both oxidant and reductant within the some molecule.

Normally it has a fiber-like structure. By use of solvents, other materials, and mechanical work, nitrocellulose can be formed to give tough, plastic-like grains. However, the energy release was fairly low and, more important, nitrocellulose is an unstable molecule even when very pure.

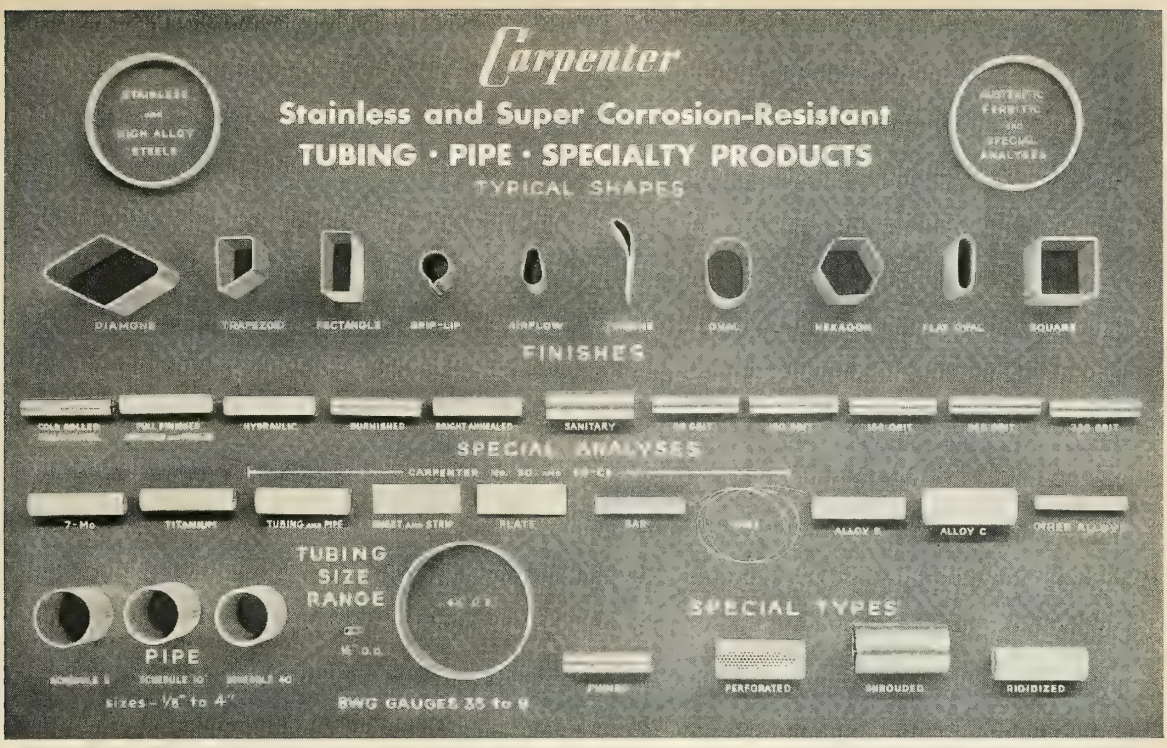
Stabilizers (such as diphenylamine) were found to prolong storage life and later nitroglycerin was added to increase the energy content. However, addition of nitroglycerin was a costly affair: it not only increased the price but also made the propellant much hotter burning and also more sensitive to shock and temperature.

Since both single and double base propellants were formed with the aid of solvents, solvent removal with larger and larger grains became more and more difficult. The newer solventless systems now offer almost unlimited grain sacle-up.

With plastics technology growing steadily after World War I, the solid oxidants (Table 1) were eyed seriously by researchers in a number of countries. The old GALCIT binders (asphalt-oil) and NDRC types (cellulosics or phenolics) are now familiar to all.

Late in the war, two important fuel-binders were added: the polyesters (Aerojet Aeroplex) and the polysulfides (Thiokol). It may be assumed that these materials form the backbone of most present composite systems.

Unfortunately, we are stuck with a meager number of good oxidizers at the present time, so, in the composite field at any rate, one might consider looking for better fuel binders.



The ideal fuel binder is a low molecular weight carbon-hydrogen compound containing as much oxygen as possible. It should be a low viscosity liquid that can bind together a large amount of solid oxidant. The mixed propellant then should harden rapidly to a thermo-setting solid.

Physicals should be good. Cost and potential availability should be attractive. In reality, however, a number of optimizations have to be made so that physicals, and ease in processing are more important parameters. Of

the fuel binders in the table, the epoxies and polyurethanes hold promise for future composites.

It is interesting to note that the Soviets are now pushing for large expansion of epoxy resin production in East Germany.

In the homogeneous class, work is now underway at several labs in the synthesis of new, stable molecules to replace nitrocellulose or nitroglycerin. Most of the work seems to be centered around organic nitropolymers. However, improvements in German-developed diethylene glycol dinitrate systems are also taking place.

For composite propellants, the future seems limited to available or readily developed oxidants or fuel binders. Since the oxidant is the heart of a composite system, a breakthrough can only come when a new or ideal oxidant is found.

Summarizing we might say that solid propellant performance is now increasing at a decreasing rate. The big holdback is in available chemicals. If *new kinds* of compounds are developed solid propellants might be pushed into the ultra energy class.

The Ideal Organic Fuel-Binder:

1. A High H/C ratio; low total C; some O; N which can go to N_2; little or no P or S.
2. For smokeless operation no metallics or halogens.
3. Density of 1.0-2.0 g/cm³.
4. Low viscosity, low vapor pressure liquid. High boiling point, low freezing point.
5. Polymerizes with heat (70-200 F) and/or catalyst. Pot life of at least 2 hours. No volatile reaction products liberated. No reaction with or decomposition of oxidizer. Low exotherm in large masses. Total cure time under 24 hours. Low shrinkage on cure.
6. Good binding at low total concencentrations (10-25% of total propellant weight). Gives propellant tensile strength of $>$1,000 psi and compressive strength $>$5,000 psi. Allow cycling of complex grains over temperature range of —80 F to 180 F. Ability to resist moisture. Stable at 250 F for over 1 year.
7. Low cost and high availability.

The Ideal Solid Oxidant:

1. Available oxygen content $>$50%.
2. For smokeless operation no metallics or halogens.
3. Density: 1.5-2.5 g/cm³.
4. Stable solid at room temperature (insensitive to shock).
5. Melting or decomposition point $>$400-700F.
6. Low coefficient of thermal expansion.
7. Non-hygroscopic.
8. Low cost and high availability.

FILLING A NEED...

ing the nineteenth century, the mechanics of fluids branched ne main stem of physical science. Physics concentrated on the oration of the structure of molecules and their components; development of fluid mechanics was guided by the need for erstanding the macroscopic phenomena associated with ships, ines, airplanes, etc. The separation between these disciplines been reflected in the organization of university departments several generations, so that there is little contact between ics and fluid mechanics departments. This lack of contact been reflected in our scientific graduates who typically have trained in one or the other of these disciplines, but almost r in both.

suddenly, however, the country faced an important problem n we had to meet the challenge of rapidly creating an operable continental ballistic missile. The re-entry of this missile into earth's atmosphere was regarded as a very difficult problem; ly because here, for the first time, we faced a scientific prob- involving the mechanics of a fluid closely coupled with im- ant aspects of molecular physics. The Avco Research Lab- ory was created to fill this need. Its senior scientific personnel trained in classical aerodynamics, atomic physics, and ical chemistry, and saw in this interdisciplinary area a unique rtunity to broaden their background and to make creative ributions in a field in which the great advances are still to ade.

laboratory has been successful in supplying vital information h only a year ago was generally held to be obtainable only ostly and time-consuming flight experiments. Our research ess has resulted in a large development responsibility being usted to this company.

interdisciplinary strength we have acquired will enable us to a major role in such problems as the re-entry of manned cles into the atmosphere from satellite orbits, in the creation thermonuclear reactor, and in other fields involving the amics of high temperature gases.

WELSBACH Ozone

..new horizons as an oxidant

Ozone provides one of the most versatile oxidants available today. It has the added advantage of introducing nothing but oxygen to the reaction.

Low in cost, efficient and always available, ozone produced by a Welsbach Ozonator might just be the answer to your oxidation problem.

Glance at a few of the applications listed below in which ozone has proved to be a better oxidant. One of them might parallel your problem . . . with ozone the solution:

- *Removal of corrosive chlorides in nitric acid recovery following atomic fuel extraction.*
- *Oxidant for rocket fuels.*
- *Chemical synthesis reactions demanding specificity and purity in the oxidant.*
- *Removal of cyanide or phenol from wastes.*
- *Oxidation of oleic to azelaic and pelargonic acids (replaces chromic acid.)*
- *Improving oxidation characteristics of mineral oils.*
- *Elimination of many industrial and sewage odors.*
- *Purification and elimination of undesirable taste, color, and odor in municipal water supplies.*

. . . and a host of new applications still being researched.

If your process calls for an oxidant, it is almost certain that Welsbach ozone will do the job better and at less cost. Why not contact Welsbach.

Write for this booklet on Welsbach Ozone Generation for Industrial Application. Please indicate Company and Title.

engineering briefs

US-KG Engine Co.s Enter Agreement

The two largest U.S. rocket engine manufacturers have entered into agreements with British firms.

Aerojet-General has signed an agreement with D. Napier, Ltd., which has developed rocket engines for the Ministry of Supply. They produce a variety of engines for both guided missiles and for aircraft applications. The aircraft applications are for auxiliary high altitude speed boost and as a main powerplant. The Napier establishment at Luton is one of Britain's most extensive rocket test installations. Napier Ltd. has been developing and manufacturing rocket engines for six years.

Initial exchange of information with Aerojet will center upon hydrogen peroxide rocket engines. Great Britain has utilized high test peroxide for safe and reliable rocket engines to a much greater extent than the U.S. where peroxide is used for turbopump drives.

Similar negotiations have been entered into between Rolls-Royce, Ltd. and North American Aviation, Inc. (Rocketdyne).

Such negotiations are expected to speed up realization of British defense plans which will be dependent to a large extent upon offensive and defensive guided weapons.

Navy Dedicates Building

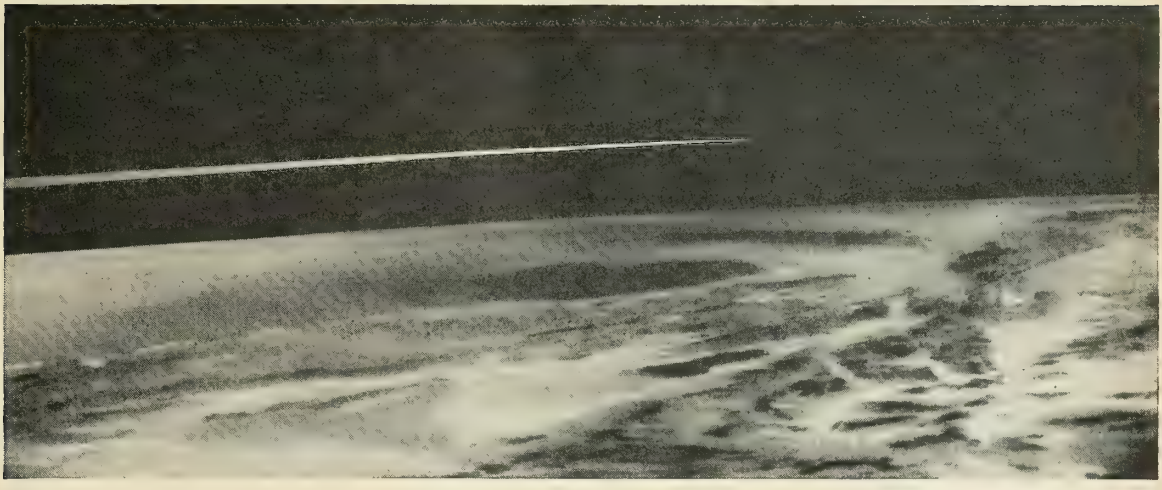
Navy has dedicated a $165,000 Bureau of Aeronautics building at El Segundo, Calif., to serve as a center for monitoring research, development and production of aircraft and missiles in eight western states and Hawaii.

R. Adm. John B. Pearson, BuAer general representative, Western Division will direct operation.

Grand Central Hikes Solid Mixing Capacity

Grand Central Rocket Co. will install a large process mixer to increase solid propellant mixing capacity by 2,500 pounds an hour.

The mixer, built by Bramley-Beken of New York, will be installed in a two-story, partly underground structure within the next two months. Mixer is reported to cost about $100,000.



Bullpup Confirmed by Navy

The Navy and Martin finally have announced the new air-to-surface missile—the *Bullpup*. In a speech at Kansas City, Mo. last month, Vice Admiral William V. Davis, Jr., USN,

Career News for Engineers!

Flight Tests are under way on one of America's most important defense projects:

The Navaho Strategic Missile

Artwork based on Official U.S. Navy Photograph

The results are secret—but this much can be told. A test vehicle designated the X-10 has gathered new aerodynamic and electronic information which will help to speed progress on the SM-64 Intercontinental Strategic Guided Missile.

The opportunity—and the privilege—to implement this revolutionary data is yours.

Twenty-eight-year-old Army vet **WILLIAM T. SCHLEICH** was graduated from Georgia Tech in 1952 with a BSAE. He joined North American as a junior engineer the same year. Seven months later Bill was promoted to aerodynamics engineer for the Navaho missile program. He was appointed Supervisor, Stability and Control Unit in October of last year. With the help of North American's Educational Refund Plan, he received his MSAE from USC. Bill and his wife are hi-fi enthusiasts and have a sound system built into their Whittier, California home.

If you accept this challenge you'll be solving tomorrow's problems—today. Here facts are collected fresh daily. If yesterday's yield proves inconclusive you'll approach the problem from a new direction. You'll travel new paths and develop new inventiveness. And you'll be guided to each breakthrough by the world's best-informed missile authorities—your own associates.

One example of the new hardware evolving from this creative engineering effort is a fully transistorized electronic commutator. This instrument increases the information-relaying capabilities of the missile's telemetering system by commutating 27 outputs at speeds of approximately 100 cycles per second. It was developed by the Flight Test Instrumentation Group.

North American's Missile Development Division is a major center of missile activity—and a pioneer in the field. As far back as 1948 its first test instrument vehicle was fired from a launching platform. Today North American has complete weapons system responsibility for the Navaho—and its test program is being conducted at the Air Force's long-range missile proving ground which stretches more than 5000 miles across the Caribbean and far into the South Atlantic.

LYLE C. BJORN has lived aviation all of his life. As a high school boy he built a glider modeled after the Wright Bros.' first flying machine—flew it from ski jumps near his Utah home. He studied engineering at Utah State and earned his BSME degree from the U of Wyoming. Lyle joined North American in 1951 and is now Group Leader, Field Test Operations at the Missile Test Facility, Patrick Air Force Base, Florida. He lives with his wife and three children near Cape Canaveral where he is an active leader in Cub Scouts.

If this sounds like the kind of career-opportunity you've been looking for—write us today. We promise you a working climate that stimulates personal growth and rewards it with responsibility, professional recognition and material benefits limited only by your own ability. Further, you can continue to grow academically with the aid of our Educational Refund Plan—and some of the nation's finest universities are nearby.

Let us know what kind of creative engineering interests you. (Please include highlights of your education and experience).

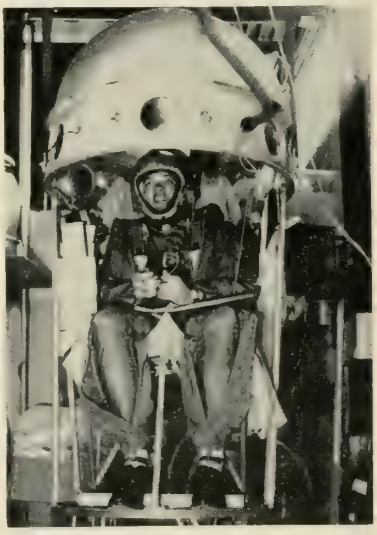
Deputy Chief of Naval Operations for Air, outlined the development of the missile and said *Bullpup* is currently undergoing Navy evaluation and will be introduced as a service weapon.



The *Bullpup* is designed to be launched from any position outside the effective range of enemy high-volume ground fire and provide sufficient accuracy to destroy small targets without excessive sorties and expenditures of many of bombs and rockets.

Industry Invests $100 Million for Missiles

Aircraft industry's investment in test and manufacturing facilities for the ballistic missile program is about $100 million, according to Aircraft Industries Association.

AIA president Orval Cook, in an editorial in *Planes*, said manufacturers put 60% of net earnings in expansion last year.

Winzen Balloon Sets Altitude Record

Capt. J. W. Kittinger, Jr. soared to 96,000 feet on June 2nd in a Winzen balloon to set a new record for manned, lighter-than-air flight.

The 28-year-old pilot landed about 80 miles southeast of St. Paul, Minn. after remaining aloft more than two hours.

The flight was part of a series of high altitude tests. Maj. David G. Simon, above, is scheduled to make a 24-hour endurance test at altitudes over 100,000 later this month.

The tests are being carried out by Holloman Air Development Center of Alamagordo, N. M. Kittinger's flight beats the old manned-balloon record of 76,000 feet set last November by nearly 4,000 miles.

Astrionics

By Henry P. Steier

Lockheed's Missile Systems Division has shelved plans to build a "hot" nuclear energy facility building at its Stanford University Industrial Park site in Palo Alto, Calif. Instead a Van deGraaff generator will be installed in the physics laboratory for work on nuclear reactions resulting from acceleration of charged particles.

•

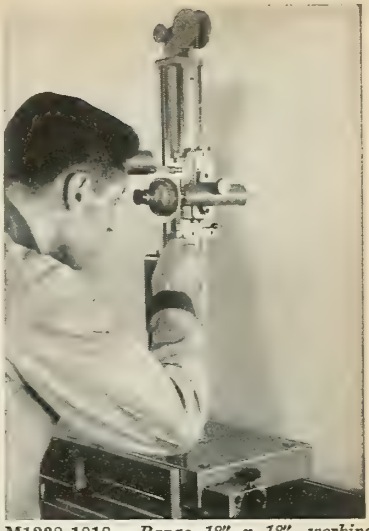
Navy missile men are reportedly interested in the highly accurate low-frequency hyperbolic navigation system developed for USAF by Sperry Gyroscope Co. for position-fixing of ballistic missile launching ships. Stabilization of the launching platform and its exact location are key factors in effective use of such missiles. Reason for Cytac development has been a mystery, especially after AF dropped it and Coast Guard and Navy picked it up with plans to build a Cytac chain along the U.S. east coast. Tactical Air Command, it has been learned, had a tactical mission needing this type of position-fixing but found the system could not fill the bill.

•

It appears that the planning program for use of SAGE (Semi-automatic ground environment) calls for control of the *Bomarc* missile as well as piloted aircraft. *Bomarc* will carry an 8-channel data link system for receiving interception data from SAGE centers. There is close similarity between *Bomarc's* data link system and that being readied for piloted aircraft use, with the exception that the latter has a visual display. One of the big contractors for the data link is Motorola, Inc.

•

Latest Pentagon "line" is high cost of electronics. Three military spokesmen in rapid succession recently hit at this matter. At the National Conference on Aeronautical Electronics Lt. Gen. Thomas S. Power, USAF Commander, ARDC said cost of maintaining leadership could reach crisis stage where it affected our civil economy. Rear Adm. Rawson Bennett, USN Naval Research Chief, said unless we force electronics cost down we will someday put the final straw on the taxpayers shoulders. James M. Bridges, Director of Electronics, Office of Asst. Sec. of Defense during AFCEA convention in Washington called attention to skyrocketing costs for weapon system electronics as a critical problem in the defense effort.



Interesting sidelight on the expenditure problem is Naval Research Laboratory record in this regard. In 1939, NRL received $2-thousand for research. In 1957 the figure is nearing $6-billion.

•

Dr. Bertram D. Thomas, Battelle Institute director, points out that "research and development is not the way to get new ideas." He says the character of the creative process has changed in the last 25-30 years. In the old days curiosity was the motivating factor. Today curiosity has given way to practical application. The character of research people has changed. He's "sure there are no pure scientists left"; there's too much need to earn a living. His parting shot—"The way to get new ideas is to give bigger salaries,"—was highly applauded.

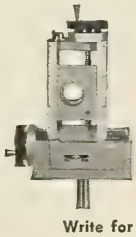
•

Dr. Daniel E. Noble, Motorola's executive vice president, recently asked if his company has given any thought to space communication problems, quickly replied: "I have had some scientific training. Therefore I must first know the problems before I tackle the answers."

M1238-1818 — *Range 18" x 18", working distance 9" to infinity. Reads to 0.001" up to 24" working distance. Protractor ocular reads to 3 minutes of arc. Image is erect.*

Cut inspection time in half

with new Gaertner Coordinate Cathetometers



These convenient, reliable optical instruments permit making precise coordinate measurements in a vertical plane. The two dimensions are measured with one setting, object does not have to be rotated. Inspection time is cut in half and resetting errors eliminated.

Versatile Gaertner Coordinate Cathetometers are ideally suited for precision measurements on large objects; also objects or points in recessed, remote, or inaccessible locations. Applications include measuring jet engine sections, complicated castings, printed circuits, bolt holes and bosses on large piece parts, traces on cathode ray tubes, etc.

Because these are optical rather than mechanical measuring instruments, you make non-destructive measurements without contact, distortion, or concern about pressure being applied to the object when making a setting. Instruments available in English or Metric system.

M1236-46— Horizontal range 6", vertical range 4". Reads to 0.0001", working distance 5" to infinity.

M1236-22— Range 2" x 2", reads to 0.0001". Working distance 5" to infinity. Shown with 19 mm mounting rod, and without telemicroscope. Instrument permits precise coordinate movement of other objects such as photo cells, probes, etc., in place of telemicroscope.

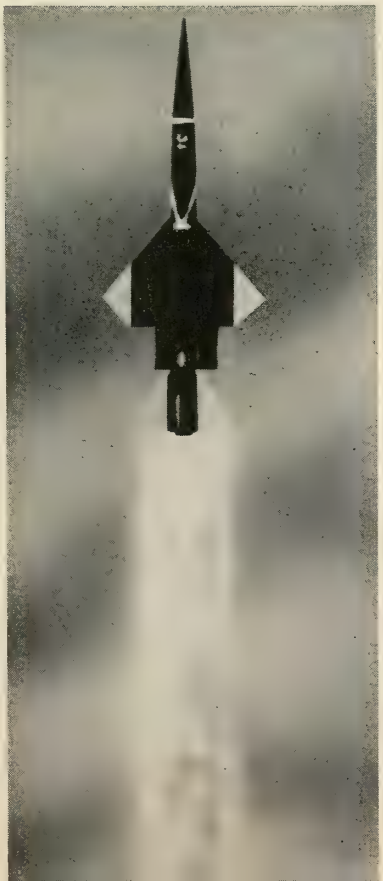
The Air Force, after a series of successful firings of the BOMARC XIM-99, has awarded Boeing Airplane Co. a contract for quantity production of the XIM-99 surface-to-air missile. The $7-million contract, initial phase of a larger one, will probably be utilized for the tooling program. Total funds allocated for the larger contract were not disclosed. Initial production plans have slated more than 70 per cent of the program for subcontracting.

According to the Air Force, the latest contract followed superior test results at Patrick Air Force Base. The XIM-99's were launched to seek out and intercept B-17 drones flying over the Atlantic. Individual XIM-99 flights have been carried out since fall of 1952.

BOMARC . . .

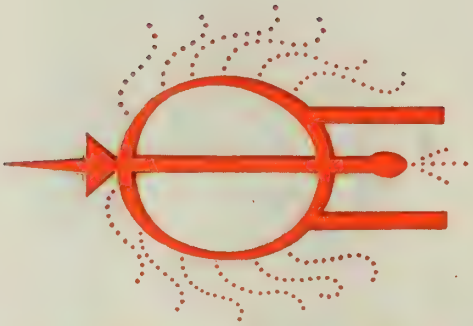
Enters Large-Scale Production

BOMARC missiles, with an operating range greater than any missile presently in use in air defense, will provide large perimeters of interception in strategic locations. This area defense role differs from the short-range point defense missiles such as NIKE and TALOS. The BOMARC is about 47 ft. long, has a wing span of 18 ft. 2 in., and weighs 7.5 tons. It is designed to operate at extreme altitudes and supersonic speeds with outstanding range characteristics. Energy required to lift the missile to operating altitude and velocity is provided by rocket and ramjet engines.



n integral liquid propellant rocket engine esigned and manufactured by Aerojet Gen- ral Corp. provides the boost, while two Marquardt ramjets supply sustainer thrust. OMARC is launched vertically from a com- ination erector and launch pad. The boost ocket provides the impetus necessary to raise he missile to altitude and sufficient velocity or operation of the ramjets. The ramjets, fter rocket burnout, provide the thrust for the cruise phase of the flight.

here are no recovery versions of the OMARC missile, although many designs ave been proposed. The advantages of a ecovery system have not appeared equal to he disadvantages imposed upon the missile levelopment. Instead, a system was devised or installing the guidance package of the BOMARC in the nose of piloted aircraft, such as the B-57.



The recent decision to use existing production facilities in Seattle for the BOMARC production program brought to a climax the search for a location, which had extended over a period of several months.

Boeing presently holds additional contracts for the experimental production model XIM-99 and the service test model YIM-99. The first production missiles will be assembled at the Seattle division's Plant I, where the experimental models are assembled.

صفة بيضة تخرج وتخرق

er-Rammah's self-moving egg

Join two flat pans; fill with an incendiary mixture; add a tail; propel by two large rockets. In A.D. 1280, Arabia's Hassan er-Rammah, gazing centuries ahead, proposed this ovoid in his "The Book of Fighting on Horseback and with War Engines."

Today, rocket-powered ordnance is foremost in American defense...and Aerojet-General Corporation is foremost in rocket power. Aerojet's solid-propellant rockets are used on the Sparrow and Regulus and on the newest, most advanced American missiles.

Nuclear Radiation . . . New Challenge for Transistor Makers

Greater Exchange of Information Needed to Speed Future Missile Development

by Henry P. Steier

ONE OF THE MOST difficult prospects in store for astrionics designers is choice of components for a nuclear environment. A key component in the designs will be semiconductor devices. Their operation basically depends on a highly uniform crystalline structure. Such structures are susceptible to radiation damage.

Semiconductor devices are already making history through their utility as size-reducing and power-drain-reducing control components in the ever more complex astrionics gear being built.

Although the status of semiconductors today represents what Dr. Daniel E. Noble of Motorola, Inc., recently called "the first revolution in electronics," their use in future nuclear powered missiles, spacecraft, manned and unmanned aircraft and tactical environments will be even more wide-scale in some weapons.

The environments to which semiconductors will be subjected might be broken down into three classes: that near a controlled nuclear reactor for a propulsion system; near an uncontrolled nuclear reaction produced by bombs or missile warheads; cosmic radiation in the outer reaches of space.

The importance of knowing the effects of radiation on materials cannot be overemphasized and has been under study for some time. But in the final analysis material effects are the lowest common denominator in the interpretation of effects on astrionics components and systems.

Although several investigators have reported within the past six years that germanium and silicon are sensitive to nuclear bombardment, the information gave little help to semiconductor devices or application engineers.

Early in 1957 the Defense Department gave recognition to the urgent need for a further exchange of information in this field and sponsored an unclassified symposium on nuclear radiation effects on semiconductor devices and materials.

Sponsorship was under the auspices of the Office of Asst. Sec. of Defense, R&D, Advisory Group on Electron Tubes. A surprising revelation to the participants was that so much work is going on. It is being carried out under Air Force, Signal Corp., Atomic Energy Commission, and industry sponsorship.

Investigation of the radiation effects on semiconductors was reported by: Oak Ridge National Laboratory; Radio Corp. of America; Purdue University; Boeing Airplane Co.; Glenco Corp.; Cook Electric Co.; Diamond Ordnance Fuze Laboratories; North American Aviation; Jet Propulsion Laboratory; National Bureau of Standards; Bell Telephone Laboratories; Hughes Aircraft Co.; Haller, Raymond and Brown, Inc.

Boeing's Pilotless Aircraft Division found these relative differences in sensitivity of transistors to gamma induced transient effects. Gamma flux was approximately 2 x 10° R/hr.

izations has been under way for about two years, and the newness of radiation investigations in this field is revealed by sometimes divergent approaches to the studies.

In fields as complex and secret as nuclear energy, and as new as semiconductor technology, the effects of limited background information and decentralized research programming are quick to show up.

Test results on radiation damage to semiconductors as revealed thus far, show somewhat contradictory results and the data is not always comparable, or applicable to practical use.

It is generally agreed that nuclear effects of concern to semiconductors are fast neutrons and gamma rays. Protection of semiconductors against the effects of slow neutrons is relatively easy to achieve with shielding.

Such shields as boron carbide-aluminum alloy are light in weight and relatively inexpensive when compared with water, concrete and the so-called "rate earths" fast neutron moderators.

In the case of nuclear powered aircraft and missiles, distance between the reactor and astrionics gear would help radiation reduction. Intensity of a radiation source is inversely proportional to the square of the distance from the source. Radiation from a source with a diameter of two feet would be down to 0.1 per cent at a distance of 60 feet from the reactor.

Measurements made by early investigators on germanium and silicon reaction to nuclear radiation were concentrated on the majority (resistivity and Hall coefficient) carrier density properties.

Changes in these properties were attributed to imperfections produced in the crystal structure of the semiconductors. The imperfections could be caused by fast neutrons, gamma rays or recoil nuclei. Or the atoms could be transmitted by slow neutrons.

Much work which had been done was on static characteristics. In a recent study by G. L. Keister and H. V. Stewart, Boeing Airplane Co., they noted that only limited information was available on the minority carriers.

The lack of minority information, it was felt, was handicapping information important to the fabrication of acceptable nuclear radiation resistant semiconductor devices.

Under a contract sponsored by the AF Wright Air Development Center, Boeing's Pilotless Aircraft division ran a test program on electrical characteristics of the transistor while the device was being irradiated.

In any application of these devices it is the dynamic situation which is of first importance. To perform its job the circuit must be operating correctly.

Boeing performed its tests with the Materials Testing Reactor Gamma Facility at Scoville, Idaho. This facility uses spent fuel elements from the Materials Testing Reactor (MTR) there, and produces a full fission product gamma spectrum. Gamma flux was about 2 x 10^6 Roentgens per hour.

Static and dynamic tests were made with gamma radiation only, to permit separate observation of defects from gamma and neutron irradiations. Other tests were made in the MTR for neutron effects.

Neutron flux was about 5 x 10^9 neutrons per square centimeter per second (nv). Total neutron dose was measured in terms of neutrons per square centimeter (nvt)[6].

The *nvt* unit used in nuclear dosimetry is an abbreviation for the number of neutrons per cubic centimeter multiplied by their velocity in cm per second and the time in seconds.

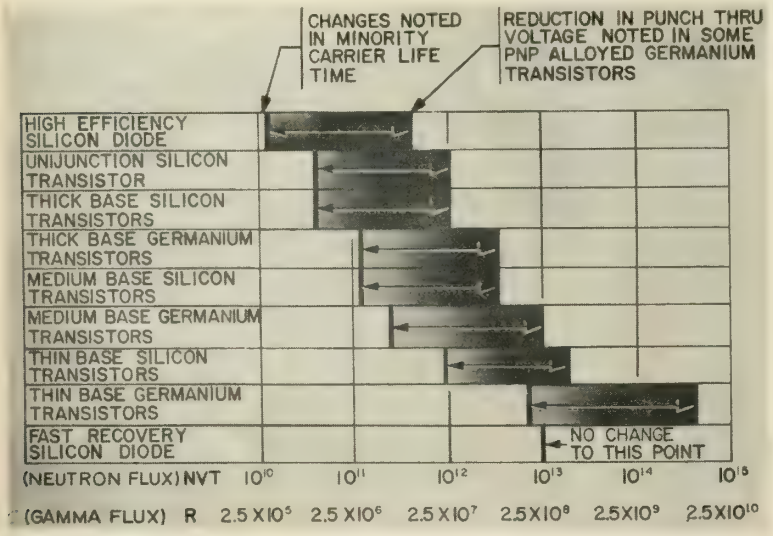
A cadmium shield 0.025 inches thick was used to moderate the slow neutrons in most tests. Transistor characteristics chosen for test were those that would define the operating region of the device. These were: collector leakage current—I_{co}; current gain —beta; and the breakdown or punch-through voltage.

Tests were also run on junction heating effects with gamma radiation. A thermocouple was placed within the transistor case on the junction and the difference in ambient and junction temperature measured. The difference was less than 10 degrees C for a gamma flux of 2 x 10^6 Roentgen per hour.

The gamma radiation resulted in a number of transient changes. Most sensitive in this regard were I_{co}; Beta and floating potential. I_{co} increased with time until removal from the flux in some cases. In others it reached a saturation point. Floating potential varied in the same manner.

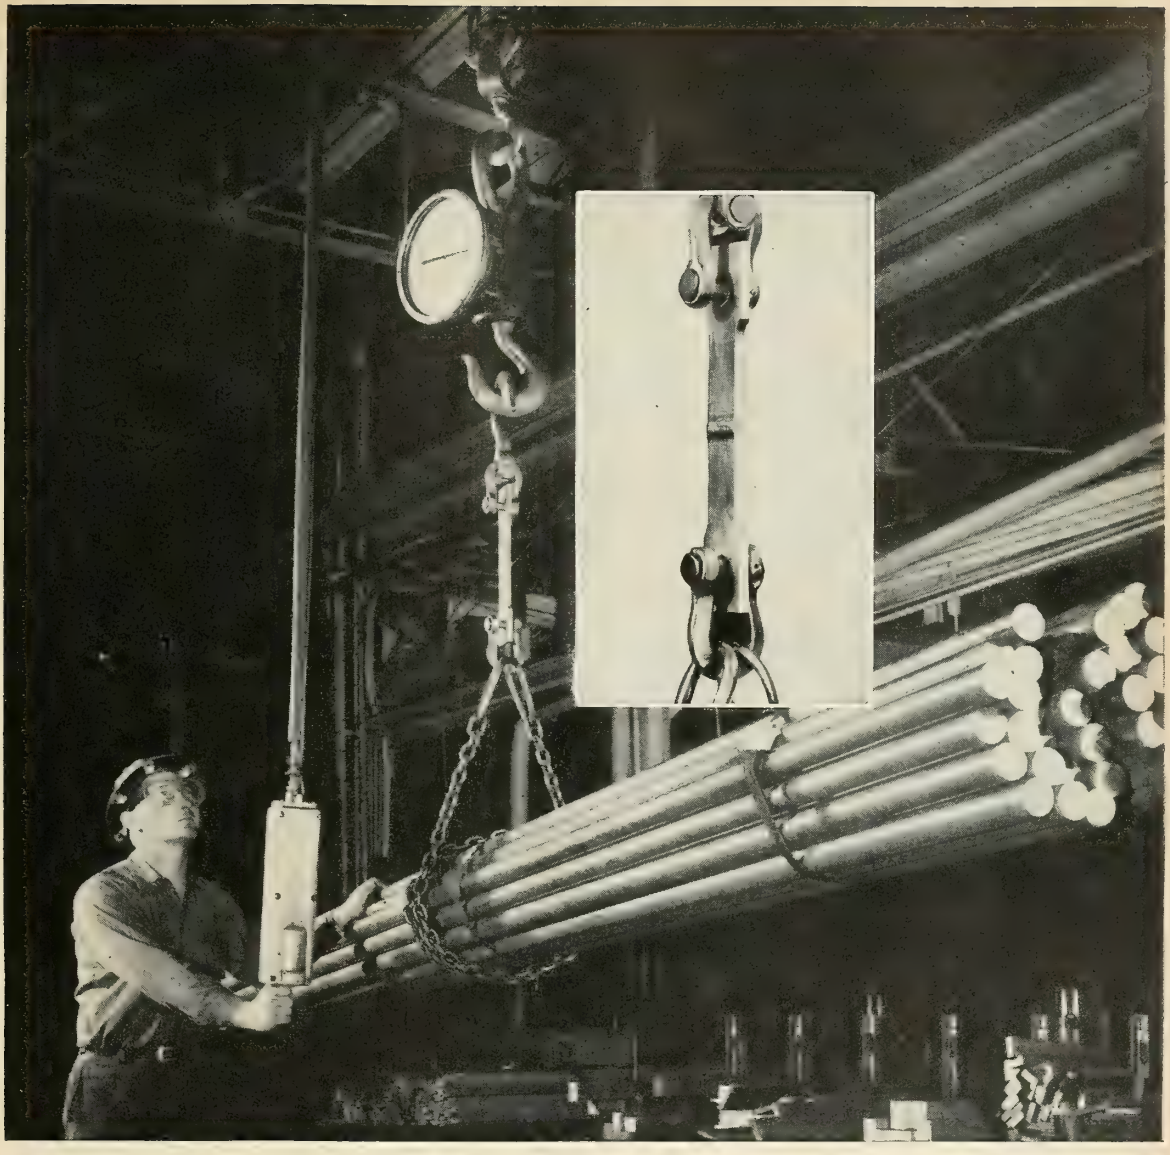
After removal from the radiation the transient effects disappeared quickly. The effects, however, varied widely between different transistors.

Examination of the types tested and their construction characteristics showed no particular relationship between construction and sensitivity to transient effects.



Another effect of radiation was induction of photovoltaic voltages in the pn junction. For a gamma flux of 2 x 10^6 R/hr. this was 10-50 volts. It was independent of circiut loading.

Noise was another effect. Noise level increased to about 25 db. This could be a big problem for applications using low signal levels. The noise disappeared after the transistor was removed from the flux.



Boeing concludes that high frequency, thin based, transistors are the most resistant to nuclear radiation, and the germanium types more resistant than equivalent silicon types.

Reports generally indicate that gamma and fast neutron radiation gamma fluxes of from 10^6 to 10^9 R/hr. and neutron fluxes of 10^{11} to 10^{13} nvt cause changes in some characteristics.

Gamma flux damage is often transient and anneals out. Neutron flux

Relative sensitivity of selected semiconductor devices to neutron and gamma induced permanent damage as determined by Boeing. Light-shaded areas indicate beginning of permanent changes. As area becomes darker changes become sufficient to affect operation in more sensitive circuit applications.

Weld Strength! Magnesium has 95% weld efficiency

In the picture above, a small arc-welded magnesium bar is supporting a load of four tons. This is one example of what we mean by "strong" when we say magnesium is light but strong. Its weld efficiency, the relationship between the strength of the parent metal and a welded joint, is very high. AZ31B magnesium alloy plate, tensile strength 35,000 psi, has a welded joint tensile strength of 33,000 psi, or a weld efficiency of 95%!

Magnesium can be arc welded, gas welded, or welded by electric resistance (spot, seam or flash). Magnesium plate ½" thick can be joined by arc welding in one pass. It can also be readily joined by most any other method: riveting, bolting, screwing, adhesive bonding and self-fastening devices.

These facts spotlight just one of the many reasons magnesium does a better job in many fabricated metal products. For more information, contact your nearest Dow sales office, or write to us. THE DOW CHEMICAL COMPANY, Magnesium Department, Midland, Michigan. Dept. MA1403G.

YOU CAN DEPEND ON DOW

damage is more permanent and changes remain after extended storage.

In the case of silicon semiconductors, it appears they are only subject to damage in characteristics depending on the minority carrier lifetime (current gain).

The new environment in which transistorized astrionics must operate presents a challenge that must be faced as rapidly as possible by researchers, manufacturers and users.

The problems are compounded by many factors. Each day more semiconductor types are put on the market. Many of them have similar characteristics but are made by much different methods and combinations of different materials.

Boeing proposes that more attention be paid to the method of manufacture and to establishing a new specification indicating a semiconductor's susceptibility to radiation.

The parameters of radiation present another challenging task for specification. The type of radiation, the spectrum it covers, integrated flux values, etc. are but some of these.

These factors are of major importance in comparing work on determining radiation damage. The flux values are not meaningful unless spectral information is included, for instance.

Boeing has suggested that punch-through voltage of a pnp type semiconductor might be used as a radiation dosimeter. This would be a true integration of spectral difference effects and germanium cross section variations. Dosimeters of this type would be inexpensive and allow accurate checks of dose or dose effects.

It may be found that the rate of radiation is very important in determining total damage. This factor would be very important in weapon systems concept planning.

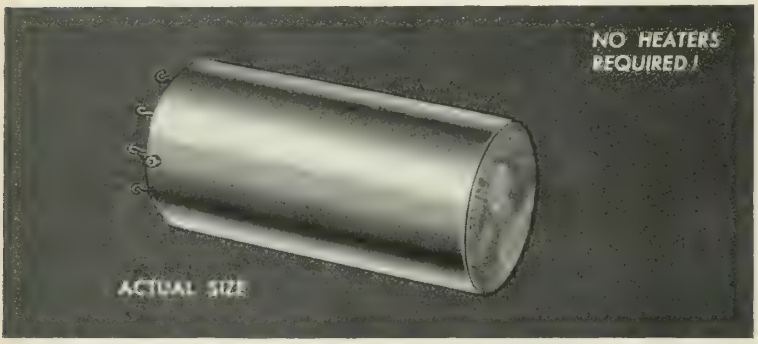
There is a multitude of environmental conditions to be anticipated. These would be contingent upon the mission of a weapon. In a conflict near-misses can be expected. These might produce nuclear clouds through which another weapon must pass.

If the missile must penetrate this cloud, radiation conditions in terms of intensity and time would be much different than under the controlled conditions in a nuclear powered vehicle.

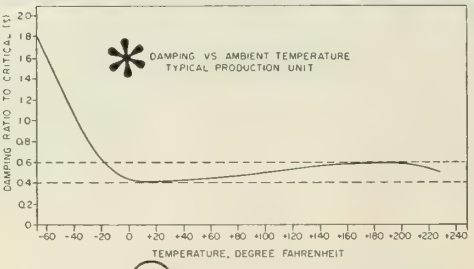
Whole new families of transistors designed for various nuclear conditions are likely to appear in time. One of these conditions might be the effects of cosmic rays.

Jet propulsion Laboratory reports that particles with 10^7 electron volts energy exist at 100,000 feet altitude. If a space craft were at altitude for a long time, say one year, cosmic radiation might be a matter to contend with.

At this time manufacturers do not have much information to go on for their radiation resistant designs. But there does appear hope for eliminating the possibility of a complete lack of suitable semiconductors for certain applications if the limited information available today is put to use soon.



This could result in production of limited numbers of semiconductor devices to meet immediate needs. And, these might be at least a few orders of magnitude more resistant to radiation than those we have today.



The systems concept planners of the future will have to dig much deeper into the electronics boxes than has been previously done. The transistor is only one of hundreds of items and materials that present radiation problems in an astrionics circuit.

To design black-boxes that have mission capability in all the various nuclear environments imaginable is going to be a science in itself.★

The SUBMINIATURE PRECISION RATE GYRO

With Constant Damping Over A Wide Temperature Range *

Check these unusual, high standard specifications

1. Constant damping (0.5 ±0.1 critical from −20° F to +220° F)
2. Subminiature size (0.937" dia. x 2.0" long)
3. Outstanding reliability (exceeds requirements of MIL-E-5272A Specs)
4. High resolution
5. Extremely high natural frequencies (up to 43 cps for 1 radian/sec; lower if desired)
6. Variety of motor characteristics available (3φ, 2φ, or split 1φ; 26V or 6.3V; 400 cps)
7. Wide variety of sensing ranges (from 0.5 radians/sec to 20 radians/sec, full scale)
8. Light weight; 3.7 oz.

MISSILE CONTROL AT MACH X CALLS FOR MACH X+Y COMPUTATION

...and Burroughs ground and airborne computers do the job

No matter how awesome the speed of today's ballistic missiles, the electronic computers that guide them must "think" far ahead of that speed to keep them unerringly on target.

This sort of instantaneous computation is a Burroughs speciality . . . which is why ours is the major responsibility for the research and development of a guidance phase of the U.S. Air Force Ballistic Missiles program (a program embracing ATLAS, TITAN and THOR).

We have the proved resources and capabilities for further research and development of even more advanced ground *and* airborne computers. And as to reliability—Burroughs has unfailingly delivered on every defense contract undertaken. Not only in electronic computation but in control systems, instrumentation, communications, data processing and others.

In all areas of our proved responsibility and competence, in fact, Burroughs stands ready to see defense contracts through every step, from research to installation and maintenance. Write, call or wire Burroughs Corporation, Defense Contracts Organization, Detroit 32, Mich., or Burroughs Defense District Offices: Paoli, Pa.—3898 Linden Ave., Dayton, Ohio—17071 Ventura Blvd., Encino, Cal.—1739 "H" St. N.W., Washington, D.C.

THE FOREMOST NAME IN COMPUTATION

Redstone In-Flight Telemetering

Studying Ballistic Missile Flight Behavior Requires Careful Pre-Flight Preparations

By Charles T. N. Paludan

Army Ballistic Missile Agency

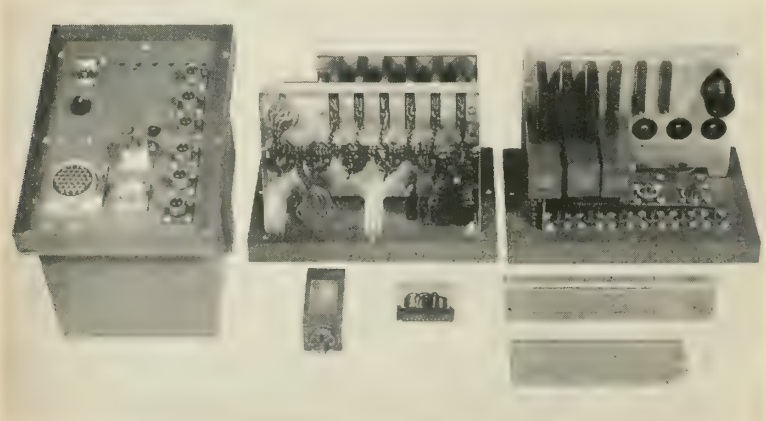
ONE OF THE MOST vital design parameters of a successful missile is temperature. In big high-speed missiles, temperature measurements in the different missile areas present a number of novel problems. These were solved for the *Redstone* ballistic missile largely by the use of conventional, available equipment. What new devices had to be designed and the special techniques developed provide a valuable basis for the instrumentation of subsequent larger, longer-range missiles.

From the initial development of the *Redstone* missile an extensive temerature measuring program was desired. These measurements were to be made during flight and telemetered back to earth.

Four measurements on the missile were required. They were: (1) surface temperature from aerodynamic heating; (2) structural temperature resulting from aerodynamic heating and from rocket engine exhaust; (3) propellant temperature and (4) ambient air temperature at various critical points within the missile.

Of the several types of gauges available, three have been used to date: thermocouples, resistance thermometers and thermistors. Thermocouples were used for those measurements where the temperature change would produce output suitable for use in the amplifier-telemeter system available.

Where low-span surface measurements were required, resistance thermometers were used. Thermistors were used for very low span measurements of the probe type.



Early in the development of the *Redstone's* temperature measuring equipment, no amplifier was available with sufficient stability under the severe environmental conditions encountered in a missile of *Redstone's* nature. Therefore it was not possible at that time to use thermocouples.

It was, however, possible to obtain large outputs from comparatively small spans of temperature change by using resistance thermometers and thermistors operating into deflection-type Wheatstone bridge circuits fed by high DC voltage. Besides ruling out thermocouples, this system had the additional disadvantage of requiring either several high voltage supplies or running the risk of one gauge's malfunction ruining the entire temperature measuring program of a given missile.

Furthermore, resistance thermometers were not readily available for measuring temperatures above 900°C because of the insulation resistance loss above that temperature. Because of the high stability of the nonamplified system, however, it continues to be used for temperature measurements of the liquid propellants power supplies (mercury cells).

Within the past year or two, second-harmonic-type magnetic DC amplifiers have become available with sufficient stability for use in the temperature measuring program. A large number of temperature measurements were required. Therefore, a universal system was evolved for use with any of the gauge types previously mentioned.

This system included a method of selecting gauge type, range, and span by means of a small plug-in unit. A stable 5-volt DC supply was available in the missile and was used in conjunction with deflection Wheatstone bridge circuits to give a small output from the resistance thermometers and thermistors. This small output was amplified in the same manner as a thermocouple

How the REDSTONE minds its measurements. Above is a typical signal adapter for converting inflight measurements into telemetry signals. Shown in the picture are the various plugs for gauge input, power supply inputs, outputs to go to the telemetering system and the large plug for pre-flight check-out service. These components can be spotted about the missile as space is available.

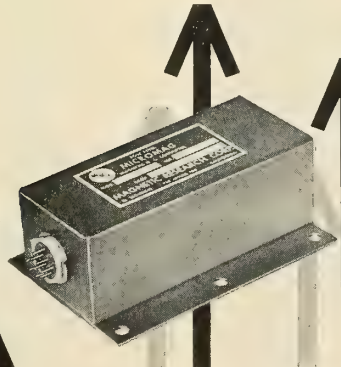
introducing a

NEW MICROMAG*

LOW LEVEL MAGNETIC D.C. AMPLIFIER

powered from 28 volt aircraft or missile system—
draws 20 milliamperes

For amplification of signals from thermocouples, strain gages, and similar low level transducers used in telemetering systems. DC voltage gain of 500 achieves 5 VDC output from a 10 millivolt DC input signal. Input electrically isolated from output. Designed for use in missile and aircraft telemetering systems, the amplifier has virtually no zero drift, and is temperature compensated to provide excellent gain stability. Operates directly from the aircraft 28 VDC supply. Draws 20 milliamps. No tubes are used, no warm-up time necessary. Potted and hermetically sealed to insure reliable operation. Designed to meet MIL-E-5272A specs.



immediate delivery from stock *specifications:*

Voltage Gain:	500
Input Resistance:	200 ohms
Output:	0-5 VDC into 100 kilo-ohm load
Response Time:	80 milliseconds
Compensated Temp. Range:	0 to 60°C (can be extended to 85°C upon request)
Power Source:	26 - 31 VDC, 20 milliamperes
Volume:	less than 7 cubic inches
Weight:	12 oz.

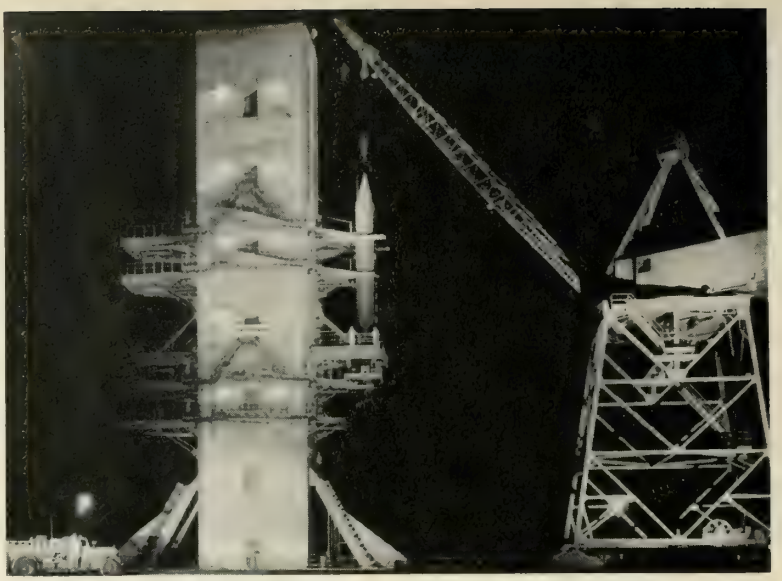
output by the magnetic amplifier.



In the *Redstone* missile circuitry used to convert end-organ output to output suitable for telemetering is commonly called an "adapter."

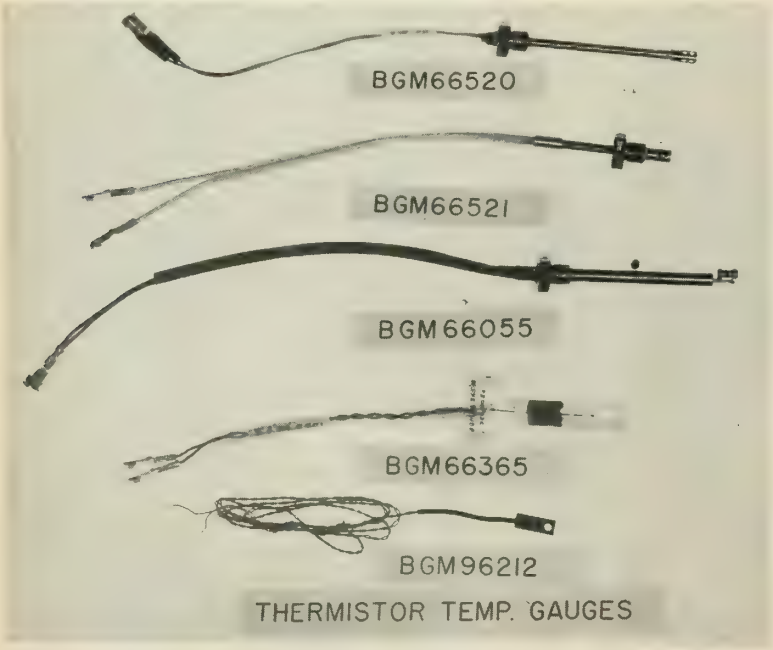
It was very important that measurements operate as satisfactorily as possible because of the non-recoverable nature of a ballistic missile. The complexity of necessary checkout actions at the time of missile fabrication and at the launching site made a semi-automatic check-out of measuring equipment imperative.

This check-out had to warn of malfunction or misadjustment in either the sensing gauge, the adapter, or missile wiring. Accordingly, the adapter circuitry included provision for a fixed known output which could be inserted through the entire system by remote control.

For all measurements an output was recorded on a strip-chart recorder and afterwards compared with laboratory data to prove proper function. Improper function would have called for readjustment, repair or replacement of equipment.

As may be seen in Fig. 1, a typical adapter included provision for six measurements. In many cases a number of adapters would be installed in various parts of the missile. The photograph shows the various plugs for gauge input power supply inputs, outputs to go to the telemetering system, and the large plug for a pre-flight check-out device. The back view reveals several magnetic amplifiers, the plug-in units for determining gauge type and range, and the wiring.

REDSTONE, predecessor to JUPITER, just before static test firing at Army's Redstone Arsenal, Huntsville, Ala.



The design of the adapter was dictated by three main requirements: (1) It must withstand severe shock and vibration conditions; (2) It must be easily accessible so that mass production techniques are applicable; (3) The finished enclosed adapter must be protected from injury or misadjustment because of rough handling during shipment, or after installation.

Before delivery to the missile, each completed adapter was calibrated in the laboratory, the missile conditions being simulated as closely as possible. A calibration curve was supplied for each measurement.

The design of all end-organs, some of which are shown in Fig. 2, was dictated by the same conditions mentioned for the adapter. In addition they were individually calibrated in the laboratory by means of water baths, ovens and in the case of the liquid oxygen gauge, a temperature-controlled liquid oxygen bath. Each type of gauge was studied in regard to time response, accuracy and reliability.

In particular regard to thermocouple measurements, a special cold-junction compensation device was developed which eliminated the need for long thermocouple leads and ice baths or ovens. One such device, referred to as a "zone box," was incorporated with each thermocouple. It used a resistance thermometer to sense the "cold" junction temperature, drew power from a mercury cell and applied a correction to the output so that the cold junction seemed to remain constant at a fixed artificial temperature. In addition the zone box was adjustable so that the "cold" junction could be set at any temperature within certain limits.

The measuring system described should not be considered the final design. However, the large number of temperature measurements have made a "design freeze" necessary in order to mass-produce hardware. Improvements and modifications are certain.★

Above is an array of typical thermistor temperature gauges for measuring inflight conditions during test firing of the REDSTONE.

MOTOROLA RADAR PICKETS IN THE "DEW-LINE" FENCE

Stretching 3,000 miles across the Arctic, special Motorola radar systems stand alert, ready to sound a warning at the first indication of an air attack over the polar cap.

The urgency of this distant early warning system called for a "crash" program for both development and production. Working in turn with the Lincoln Laboratories at M.I.T., Bell Telephone Laboratories, and the Western Electric Company, Inc., Motorola engineers came through with radar systems for the complete line within a 14-month period.

This is only one example of the military electronic equipment being developed and produced by Motorola for the varied military applications.

Underwater Instrumentation

Problems of Missiles That Live Beneath the Oceans Require a New and Different Look at Instrumentation

WITH THE ADVENT of submarines that do 60 knots or better, Fleet Ballistic Missiles that can be fired from underwater to deliver a devestating thermonuclear blow in the heart of the Soviet land mass and torpedoes that top 150 knots, the undersea ocean becomes a military environment of prime importance.

The need to know all there is to know about it gains a high priority. Not only must all the constants of its state be known for any particular moment, but these must be charted, if possible, as they change day-by-day and hour-by-hour.

As research rockets and balloons are sent into the upper air to learn about the fringes of outer space, so must instrument assemblies be sent into the deepest ocean depths to probe and record the darkness man knows least about. Underwater instrumentation, which for years has been the oceanographers more-or-less private tool, now becomes an esential military technology.

Perhaps the most critical factor in undersea warfare is sound: its attenuation at different frequencies and its refraction with changing water density. These properties are affected by temperature, pressure, salinity and the type and amount of biological life present. Some of these are in turn dependent on the penetrability of light, both visible and invisible, the tides, ocean currents, atmospheric conditions, proximity of fresh water sources, etc.

Underwater instrumentation is necessary to measure these and other characteristics. In the operational military field, new requirements are encountered—such as a passive listening device that can hear and identify a noise source several hundred miles away or a "smelling" device that can pick up and track a ship's wake.

The following takes a brief look at some of the problems encountered in underwater instrumentation and how they are solved. It is not so much concerned with detailing specific solutions to specific problems as it is in generalizing approaches to this unusual missile environment.

Oceanographic instruments may be conveniently divided into two major groups: Those which are designed to resist pressure or are pressure protected, and those which are in pressure equilibrium at the depth in which they operate. Generally these instruments are fluid filled. In the latter class of instruments it is obvious that all internal components, condensers, resistors, and electronic tubes must be designed to withstand the pressures at the operating depths.

In general design limitations, 15,000 psi is a working maximum. Where light sources are required, a standard flash-light lamp, Type G 3½ bulb, will withstand pressures of the order of 20,000 psi.

Sub-miniature radio tubes using the T 3½ envelope withstand pressures in excess of 15,000 psi. It should be pointed out, however, that not all makes of sub-miniature tubes are suitable. In normal operation the electron tubes and components are directly immersed in oil, frequently silicone oils where the dilectric characteristics are important. Cheaper oil such as Shell deodorized spray base, which is a highly refined, sulphur-free kerosene, is used.

DC motors, AC motors, relays and most moving contact electronic components will operate quite satisfactorily in this oil filled high pressure environment. In fact, oil filled vibrator type inverters have been used successfully. One of the useful by-products of this strange environment is the fact that under high pressure it is impossible to have any contact arcing.

Telemetering is done using standard RDB telemetering channels for subcarriers. The signals may either come up over single or multiple conductors and often use the sea as a return circuit. The approach at the Scripps Institution of Oceanography is toward simultaneous, continuous telemetering using FM and the RDB subcarriers and recording on deck or ashore using function plotters and magnetic tape.

Magnetic tape has many advantages. Perhaps most important is that it makes possible detailed analysis on return to the laboratory along with automatic data processing.

One example of underwater instrumentation is the telebathyphotometer, telemetering bathyphotometer. It is essentially a deep sea photometer. This particular instrument is controlled from the surface and telemeters all information back over a single wire circuit using a sea return. The instrument is relatively slow in response due to the fact that the functions being measured are not changing at a very high rate.

Its telemetering circuit is DC and is independent of external circuit voltages and polarization. The design depth of this particular instrument is approximately ½ mile. The major depth limitations are due to the somewhat uncertain strength of the pure crystaline sapphire window. The temperature sensing element is not designed for a high speed of response as this is not a fundamental requirement.

In order to facilitate operations in a high relative humidity when the case must be opened, the subassemblies which are susceptible to moisture, are unitized and are each hermetically sealed, having their cases flushed with anhydrous nitrogen. This makes it possible to operate under rather adverse circumstances when using high impedance circuits. On completion of assembly in the field or after a change of batteries the entire instrument is flushed out or purged with the anhydrous nitrogen.★

electronics briefs

Sperry Gyroscope Reveals New Plant

Sperry Gyroscope Co. has revealed that it is operating a completely new facility for producing super-precise gyroscopes needed for long range missiles, aircraft and missile-launching Naval vessels.

Recently the identity of one of the Sperry inertial platform projects was revealed when the SINS (Ship's Inertial Navigation System) was announced. Originally the term meant Submarine Inertial Navigation System.

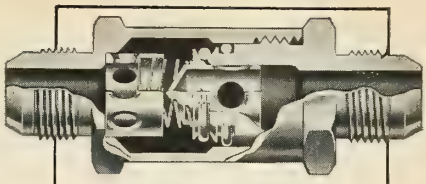
According to F. D. Braddon, chief engineer, Sperry Marine Division, new and formidable navigation problems are encountered by atomic submarines capable of "sustained" submergence.

With new tactical uses planned for the submarines, present standards of navigation are unsatisfactory, Braddon said. One new use is believed to be underwater missile launching.

Such launching would require exact information on heading, roll, pitch and position. An added requirement, not imposed on airborne systems would be the requirement for operation of the inertial platform for periods of months.

Universal Transistor Takes Larger Plant

A 500% sales increase in two years—with even faster growth anticipated—has resulted in the acquisition of a new air-conditioned 12,500 square foot plant by Universal Transistor Products Corp. at Westbury, Long Island, N. Y.



Universal Transistor's sales and advertising offices have also been expanded to one and one-half full floors at 143 E. 49th St., New York City.

Universal Transistor manufactures commercial and military transistorized power supplies ranging from low-power consuming units for radios and radiation detectors to high power units for rockets, missiles, microwave stoves and electronic flash units.

Honeywell Aero's Employment up 1500

The Aeronautical Division of Minneapolis Honeywell Inc. now employs 6500 people, a gain of 1500 in 12 months. The seven-year old division attributes this gain largely to increased work on missiles and automatic flight control systems.

one drop of leakage can destroy a $1,000,000.00 missile!

ANNOUNCES

. . . important openings on our guided missile research and development staff for men who wish to identify themselves with an organization whose prime purpose is scientific advancement.

Because the Applied Physics Laboratory (APL) exists to make rapid strides in science and technology, staff members require and receive freedom to inquire, to experiment, to pursue tangential paths of thought. Such freedoms are responsible for findings that frequently touch off a chain reaction of creativity throughout the organization. As a staff member of APL you will be encouraged to determine your own goals and to set your own working schedule. You will also associate with leaders in many fields, all bent on solving problems of exceptional scope and complexity.

Equidistant between Baltimore, Md., and Washington, D. C., our new laboratory allows staff members to enjoy suburban or urban living and the rich cultural, educational and research facilities offered by both cities.

Openings Exist in These Fields:

DEVELOPMENT: *Stability and control analysis; ramjet engine design; preliminary design and wind-tunnel testing; electronic guidance and control systems.*

RESEARCH: *Interference and heat transfer phenomena; internal aerodynamics; hypersonics, turbulence, shock wave phenomena; combustion.*

SEND NOW FOR OUR NEW 30-PAGE PUBLICATION DESCRIBING IN DETAIL THE SCOPE OF THE LABORATORY'S PROGRAMS AND THE UNIQUE ENVIRONMENT IN WHICH STAFF MEMBERS WORK AND LIVE.

Space Medicine

by Hubertus Strughold, M.D., PhD.

A fifty-five page report is now available on the presentations at the Summary Session of the Astronautics Symposium held in San Diego, California, on February 18-20, 1957 under the sponsorship of the U.S. Air Force Office of Scientific Research and the Convair Division of General Dynamics Corporation. This publication also contains a summary of the Human Factors Panel, which dealt essentially with radiation hazards, human enigneering and psychological problems in closed systems, human logistics in satellite operations, and space law.

•

On May 10th, at Brooks Air Force Base near San Antonio, Tex., a formal groundbreaking ceremony was held for the new headquarters of the USAF School of Aviation Medicine. Among the many officials attending were Congressman Paul Kilday of Texas; Major General Dan C. Ogle, Surgeon General of the Air Force; and Major General Dean C. Strother, Commander of Air University. The ceremony was conducted by Major General Otis O. Benson, Jr., Commandant of the School, which now is at Randolph Air Force Base, Tex. The mission of the new school will include research and teaching in space medicine.

•

The Aero Medical Association held its 28th annual meeting on May 6-8, 1957 in Denver, Colo., under the direction of its president Jan H. Tillish of Rochester, Minn. The meeting was attended by more than 1,100 persons. A special session of the Space Medicine Branch was held on the last day. The following topics were presented: Cosmic ray dosage during the giant solar flare of Feb. 23, 1956; medical aspects of the U.S. Navy stratolab program; sealed cabin atmospheres; experimentation in the space cabin simulator; weightlessness in space operations and in water; and the visibility of artificial satellites.

On the afternoon of the same day, a symposium on space travel was conducted by Col. Paul A. Campbell, USAF (MC). This session presented views on space travel, as seen by the propulsion engineer, the astronomer, the astrophysicist, and the test pilot. In addition, problems of instrumentation and survival, the space travel implications of the Vanguard Project, and the possibility of a habitable extraterrestrial environment that could be reached from the Earth were discussed. The Symposium was attended by over a thousand people. The papers from both sessions will be published in the Journal of Aviation Medicine.

•

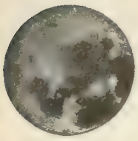
A series of thirteen half-hour educational television programs on space medicine, under the title, "Doctors in Space" is now nearing completion at the University of Houston, Texas. These programs, financed by the Ford Foundation, will be distributed by the National Education Television Center of Ann Arbor, Mich. Some two dozen experts in space medicine and its related fields, including rocket engineers, test pilots, and Air Force and Navy specialists, have taken part in the discussions, which cover the entire range of human factors involved in space operations. The scripts have been prepared by Mr. Green Peyton, Chief of Information Services at the School of Aviation Medicine.

•

A Symposium will be conducted by the writer of this column on "Problems Common to the Fields of Astronomy and Biology," June 17-19 at a joint meeting of the International Mars Committee and the Astronomical Society of the Pacific.

The topics include a "Survey on Astrobiology," "Spectroscopic Evidence of Vegetation on Mars," "The Behavior of Micro-Organisms Under Mars-Simulated Environmental Conditions," "Balloon Capabilities for Astronomical Observations," and "Application of Recent Advances in Physiological Optics to Astronomy."

NEW ROCKET POWER



from Petroleum by Phillips

Phillips solid propellants for rockets, made from low cost petrochemicals, come in a wide range of impulses for a variety of applications where required. These new solid propellants can be made relatively smokeless. They operate successfully at temperatures from —75 F to 170 F. Insensitive to detonation by impact or explosion, they are also capable of being stored for long periods without deterioration. Exhaust gases are noncorrosive and relatively low in temperature. The facilities of the Phillips operated Air Force Plant 66, near McGregor, Texas, are completely equipped for development, testing and manufacture of rocket motors. Consult Phillips about *your* propulsion needs.

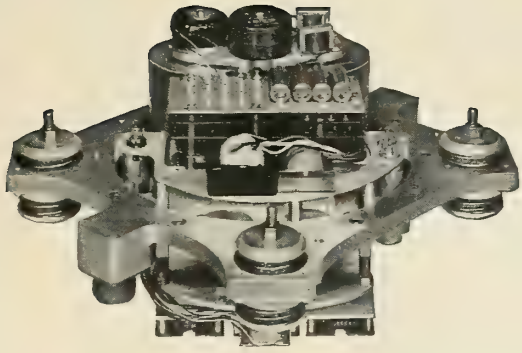
Missile Miscellany

Is AF rushing Thor into production in hopes it will be too late and too costly to give the nod to Jupiter even if Army missile proves best? That question from a top Army missile man who hopes AF in evaluating Jupiter won't "make the rules after the game has been played" and thus guarantee pro-Thor decision. He also thinks selection should be made solely on missile's merits—its ability to go accurately from point A to point B whenever button is pushed. Sounds logical.

Meanwhile, whole business may become academic as trading of Jupiter and Thor knowhow speeds up (Thor may adopt Jupiter thrust control guidance: Jupiter has incorporated Thor anti-slosh devices in fuel tanks) and the two controversial IRBM's take on a certain similarity. . . . And while Patrick wags have tagged Thor the civil service missile "because it won't work and you can't fire it," Jupiter—the first IRBM to break the record for the over-1000-mile dash—has solved its (and Thor's) gas generator exhaust problems. These stemmed from shift from peroxide to hot drive for auxilliary power turbine. Backwash burned out directional controls on main engine.

In the fantastic tales department, this page hears on what should be good authority, of 12 eight-or-nine-foot diameter spheres with three-eighth's inch thick stainless steel skins being rushed to Patrick AFB "to be crammed with instruments and fired before first Vanguard launching." Interesting, if true, for these toys tip the scales at a ton apiece empty!



Last month's speed for Aerojet torpedo should have read 155 knots instead of 140 . . . More on underwater: Power of single nuclear plant for submarines tops 30,000 horsepower . . . Will USAW system require volunteer frogmen to listen for lurking subs the way DEW requires Ground Observer Corps? . . . Japs are building a 30,000 ton underwater oil tanker.

And an expert on the subject suggests the difference between engineers and others who write is that engineers say "a coffee containing cup" when they mean a cup containing coffee . . . Aviation pioneer Glenn L. Martin could have meant missiles when he said: "Structures and machines are unforgiving of the cheater and inevitably indict those who toy with the facts."

Some signs of our times include the fact that you can now buy surplus Lark liquid rocket engines in Los Angeles . . . Space Flight Inc. has been formed in Washington, D. C. . . . Dr. Stuhlinger has an ion-propelled space ship design with a 150-ton payload and a 23,000 kw power plant . . . If General Schriever had had his way, Western Development Division would now be called Space Weapons instead of Ballistic Missile Division . . . Distribution of booklet "Toward Outer Space," prepared for employee take-home racks, now exceeds 500,000 . . . Something, this page hears, that "can hit a football 100 miles up" may soon be fired from Patrick—an anti-missile missile, maybe? . . . National Science Foundation is building 150-foot diameter celestial listening antenna in West Virginia. . . . A nuclear physicist probing space propulsion problems claims science-fiction writers are all wrong—"They're too conservative" . . . With the trend towards high-energy propellants, it may be significant that chemical industry can supply 100 tons of fluorine per day, if the market demands.

As though missile testers weren't having enough trouble fighting fires from fizzled missiles, radio-gremlins now rear their unpredictable heads. Note: The Bomarc whose engines were cut off a few feet from launching by a stray radio signal from the pad next door; the lady taxicab dispatcher in Los Angeles who unwittingly brought ulcers to Firebee developers by repeatedly popping drone's parachute ahead of time. Postal regulations prohibit publication of Patrick AFB views on radio hams in South America, who are beyond the range of FCC control . . . And for a new twist in travel, note to the right, a pattern for escape. . . .

Here is the first photograph of the guidance reference system for Project Vanguard. Designed and built by Honeywell Aero, this sensitive electronic mechanism must keep the finless rockets on course despite intense vibrations and tortuous accelerations hitherto unknown. Because of these rigid demands, rugged, precise HIG-6 gyros were selected to sense pitch, roll and yaw in the system. The Vanguard Reference System is another example of Honeywell Aero's leadership in air-borne control systems.

AERONAUTICAL DIVISION, MINNEAPOLIS-HONEYWELL

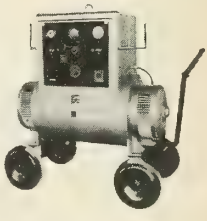
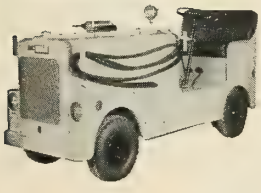
CHECK HOBART MGC

. . . for precision and accuracy in 400 cycle

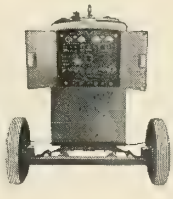




400 cycle 60 kva motor generator set

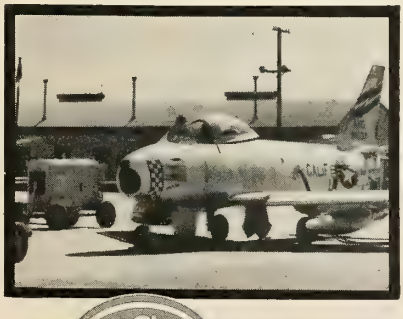
For the coming new jet transports, as well as for the military jet advancements, there is an even greater need for closely regulated, dependable 400 cycle genetators. You need not look any further than the complete Hobart line—many models to choose from, all designed to do the specific job you have. You have a big investment in your aircraft and controls. Protect that investment with the best available equipment for ground tests and checks. It's better to buy the best than wish you had.

ELECTRIC MOTOR DRIVEN



Induction motor driven 400 cycle generators with capacities of 3.75 to 37.5 KVA. Synchronous motor driven generators with capacities of 7.5 to 12.5 KVA. Furnished complete with all controls and instruments. Ideal for production or test line, or missile launchers.

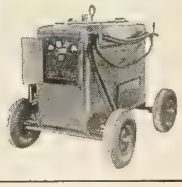
SELF-PROPELLED



For busy airports and test areas, this self-propelled design saves space and time. 400 cycle AC generators of this type are available in similar capacities as trailer type.

GAS ENGINE DRIVEN

Commercial and military models are in production. 400 cycle AC generators with capacities from 12.5 to 125 KVA, gas engine driven, or 37.5 to 125 KVA with Diesel engine drive.



. . . also CHECK these versatile DC units–

A dependable source of regulated 28 volt DC power is still required for many commercial military aircraft and missile applications. Hobart generators, designed for your specific job, give you many time and cost saving advantages.

NOW . . . a high speed, over-the-road, ground power unit. Available in two models, 1000 or 1500 amperes, 28.5 volts, DC, this mobile power plant will deliver auxiliary power anywhere on the airport. 400 cycle AC also available truck mounted.

Gas Engine Driven: Capacities of 200 to 1500 ampere for jet or reciprocating engine starting and aircraft testing. For flight line use away from electric power. Complete with all controls, DC cable and portable mounting.

WRITE, WIRE OR PHONE—NOW—FOR COMPLETE DETAILS.

NO ROOM FOR CROSS-TALK ERROR?

...CALL GIANNINI!

Low cross-talk, high sensitivity, and small size are combined by Giannini in this newest family of axial accelerometers. Covering the ranges of ±1g to ±40g, three standard hermetically sealed models offer a wide variation of potentiometer resistances, natural frequencies and resolution.

Consisting of a relatively large seismic mass, spring restrained, and supported by linear ball bushings on a case-hardened steel shaft, these units, because of resulting low coulomb friction, have a threshold as low as 0.02g, and cross-talk error *less* than 0.01g/g.

For a ready solution to critical acceleration instrumentation, call or write Giannini, the largest producer of precision telemetering and control transducers in the world.

SPECIFICATIONS

RANGES: ±1g to ±40g
RESISTANCES: 2000 ohms to 10,000 ohms
RESOLUTION: 0.25% to 0.5%
NATURAL FREQUENCY: 2.8 cps to 54 cps
THRESHOLD SENSITIVITY: 0.02g to 0.04g
CROSS-TALK ERROR: 0.01g/g

Bendix W TYPE
HEAVY-DUTY
ELECTRICAL CONNECTOR

Intended for use with jacketed cable and not requiring ground return through mating surfaces, this connector incorporates sealing gaskets at all mating joints.

W-Type Bendix* Connectors also incorporate standard Scinflex resilient inserts in established AN contact arrangements. Shell components are thick sectioned high-grade aluminum for maximum strength. All aluminum surfaces are grey anodized for protection against corrosion.

It will pay you to remember that for the really tough jobs, where ordinary electrical connectors just won't do, be sure to specify the W-Type Connector.

Complete specifications and details on request.

International Scene

By Anthony Vandyk

The Bristol Aeroplane Company's investment in guided weapon development has now reached the point where it is the largest single activity except for the Britannia turboprop transport. This was revealed when the Bristol organization announced that its *Bloodhound* SAM is now in production. The ramjet powerplant of this supersonic missile is manufactured by Bristol Aero-Engines while the radar and servo control guidance equipment is supplied by Ferranti. Overall responsibility for the *Bloodhound* has been entrusted to Bristol Aircraft. Both Bristol Areo-Engines and Bristol Aircraft are subsidiaries of the Bristol Aeroplane Co. The *Bloodhound* is described by its manufacturer as a complete missile defense system including ground warning radar stations, control stations and the missile itself. As such it should be attractive to the many foreign nations in need of "packages" of this type.

•

The first launching of the de Havilland *Firestreak* infrared-seeking AAM from an aircraft took place in a most undramatic way. The aircraft, a Venom all-weather fighter, was stationary on the Pendine Sands near the Aberporth range in Wales. The nose of the aircraft was pointed out to sea and jacked up, and an anti-blast door was fitted over the landing gear. The chief test pilot of the de Havilland Propellers and the *Firestreak's* system's engineer, D. de Villiers and C de B. White, respectively, entered the cockpit and adjusted their safety straps. White pressed the firing button and the missile left the aircraft successfully.

MISSILE SYSTEMS ELECTRONICS

Activities at Lockheed Missile Systems' Research Laboratory in Palo Alto cover virtually every field of electronics related to missile systems. Inquiries are invited from those who desire to perform research and development of a most advanced nature. Please address the Research and Development Staff, Sunnyvale 7, California.

Here staff members discuss a laboratory model of an airborne component of a guidance system. Left to right: Dr. R. J. Burke, telemetering; E. A. Blasi, antennas; K. T. Larkin, radar and command guidance; Dr. S. B. Batdorf, electronic division head; Dr. H. H. Leifer, solid state; S. Janken, product engineering.

World Astronautics

By Frederick C. Durant III

The American Rocket Society has completed a full circle on aims and interests. Originally founded in 1930 under the name American Interplanetary Society, the ARS published a journal, "Astronautics," from 1932 to 1944. The avowed purpose of the society was to encourage the development of manned space flight. Rocket engines were designed and operated by this small group of earnest amateurs.

By 1945, however, the problems of space flight appeared greater and greater. Some of the industrial barons of the rocket industry didn't like the "crackpot" influence. The society renamed itself—its present title—and hedged further by renaming its journal "The Journal of The American Rocket Society," later, "Jet Propulsion." Now, it is announced that this July the ARS will publish "Astronautics" as a sister magazine to JP.

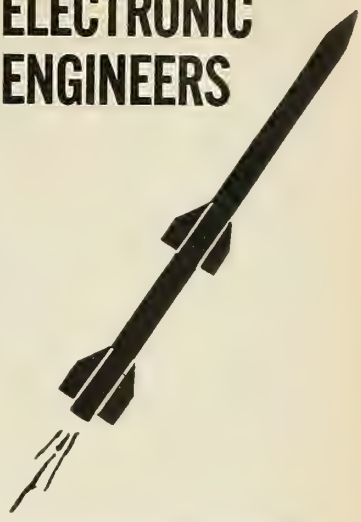
The full story of the trials and tribulations of the directors and officers of the ARS during the past decade have never been disclosed. Certainly there has been a lot of heat behind scenes between right and left wingers. When the current president of the ARS was a director some years ago, he stopped attending board meetings because he was unable to elicit any enthusiasm over astronautics. But times change. Astronautics is no longer a dirty word and those who have had faith through the years, such as Ed Pendray, Bob Truax and Andy Haley may understandably be excused a grin of self-gratification.

In retrospect it might be argued that the conservative approach was actually the better. The society was accepted more readily by the professionals and the policy battles provided a natural yeast for the rapidly growing organization. Let's hope the yeast doesn't disappear.

•

At first thought one would believe that if a satellite is accelerated in its orbit by additional thrust, it would move to an orbit of greater altitude and have a higher velocity. The larger orbit would be expected from the balance between centripetal force and the force of gravity. Actually, in moving to a higher altitude the satellite velocity is reduced. Energy is absorbed by the satellite mass and retained as potential energy. Satellite velocity at 300 miles altitude is about 18,000 mph. At 8,000 miles altitude, satellite velocity is only 10,000 mph. Escape-velocity from the greater orbit is about one-half that of the lower.

•



A. G. Haley, Washington lawyer and astronautical legal expert, recently witnessed a firing, under Eugen Saenger's supervision, of a hot water booster rocket in Stuttgart's Forschungsinstitut fuer den Physik der Strahlantriebe. One static run of this unit costs only about 25 cents. On noting Haley's surprise at this low figure, a German was overhead to comment, "That's the first time I ever saw an American amazed by a *small* number!"

•

At the Space Flight symposium held at the Cambridge meeting of the American Astronomical Society recently this question was asked of SAO Director Dr. Fred L. Whipple: "What are the odds of at least one of the U.S. satellites being placed in orbit?" The reply: "Ninety-nine per cent." When questioned as to the value of space flight to the man-in-the-street, Dr. Whipple gave serious consideration and replied, "About the same as the cyclotron was in atomic research 20 years ago." It is always hard to justify basic research, particularly in terms of dollar value. How much was $e=mc^2$, the postulated relationship, worth 20 years ago?

Another speaker, Dr. Gerard deVaucouleurs, who is a recognized authority on Mars related ". . . After many hours observing Mars, I came to the conclusion. . . . that is, it is a long way off and you cannot see much!"

ELECTRONIC ENGINEERS

Here is an excellent opportunity for a challenging career with Fairchild working on a new U.S. Air Force Missile.

Immediate openings exist for experienced and qualified electronic engineering specialists in these challenging categories:

A DIVISION OF FAIRCHILD ENGINE AND AIRPLANE CORPORATION

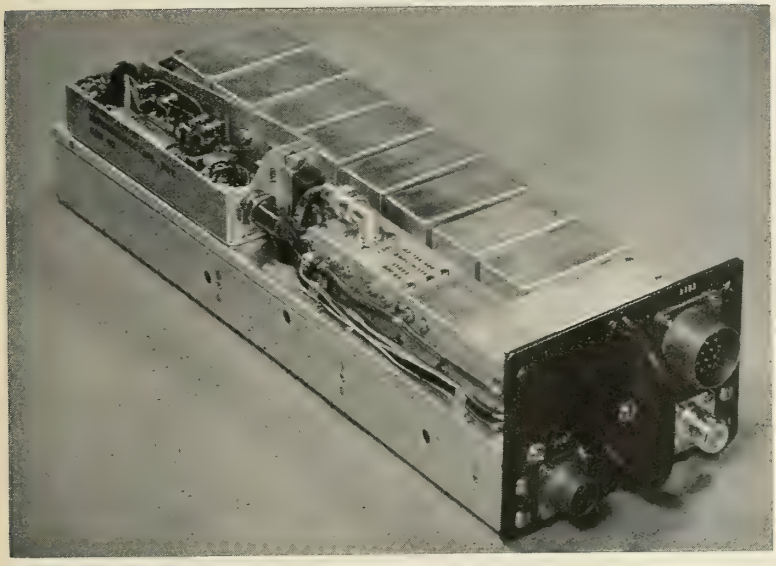
R. B. HURLEY, holder of degrees from the University of California and University of Southern California, is a Design Specialist at CONVAIR-*POMONA*. He is a nationally-recognized author and lecturer in the field of transistors.

"Engineers—here's how we're taking part in the electronics revolution toward solid state devices"

"Here at CONVAIR-*POMONA*, we are constantly studying ways to apply the new miniature solid state electronic devices: the diode, rectifier and transistor. So new is this semiconductor infant, and so vast its future—both for the military and industry—that our teams of electronics engineers actually 'go to school' under some of the foremost experts in the field.

"As the *first* fully-integrated missile plant in the U.S., CONVAIR-*POMONA* designs and builds the Navy's TERRIER supersonic missile. And, realizing the potential value of solid state devices in meeting the critical requirements of such airborne missiles, we initiated a 'transistor program' early in 1953. This program has multiplied many times to become one of the most important in the industry.

"You, as an engineer, can appreciate the tremendous expansion that will come in the application of solid state electronic devices in the next few years. And you can readily understand the advantages of studying and working with these devices, guided by the advanced thinking you will find at CONVAIR-*POMONA*.



"You'll like the atmosphere here, where you see and feel accomplishment. And you will enjoy living in Southern California's beautiful Pomona valley. For greater career opportunity—*for your future's sake*—send for more information about CONVAIR-*POMONA today!* Write to: Engineering Personnel, Dept. M-3

NEW MISSILE PRODUCTS

GUIDED MISSILE RECEIVER

Modular packaging techniques have been applied to a 400 mc radio receiver designed by Bell Aircraft Corp. for conditions where vibration presents a problem. For use where demodulated signals for the activation of a communications system are needed, the receiver is said to provide a high signal-to-noise ratio, high sensitivity and stability, and wide bandwidth.

Bandwidth within the tuning range is 402-420 mc and plug-in assemblies are available to extend this to 500 mc. Easy servicing is accomplished by modular plug-in units. Power input required is less than 50 watts and the receiver may be operated in a 15g environment from 5 to 2000 cycles at temperatures from —55° to +72°C.

Circle No. 212 on Subscriber Service Card.

AC ACCELEROMETER

A new accelerometer by Genisco, Inc. uses inductive output in conjunction with the sensing element of the Genisco Model DDL accelerometer. Standard range is 0.1 g to 10 g.

Voltage input is 28 volts or on an optional basis is 115 volts at 400 cycles or 5000 cycles. Output voltage is 10 volts maximum for 28 volt input for ranges of 1 g or higher.

Circle No. 219 on Subscriber Service Card.

WIDE RANGE ACCELEROMETERS

Columbia Research Laboratories offers wide range Accelerometers, Series, 400, employing barium titanate in compression and having natural frequency of 75kc. These instruments operate over a broad acceleration range from 0.03g to 40,000g and over a frequency range from 0.05 cps to 20,000 cps, with a sensitivity of 30 mv/g±5% throughout usable range. Pickups are available in various sizes, weights and mounting configurations.

Circle No. 218 on Subscriber Service Card.

MISSILE MOTOR

New dc motor developed by Electrical Engineering and Manufacturing Corp. for missile and rocket applications weighs 7.25 lbs. and conforms to Spec. MIL-8609.

EEMCO Type D-927 motor is rated at 0.5 hp at 9,900 rpm continuous, terminal voltage 27 v, 18 amps. An optional two-circuit noise filter for ungrounded systems adds one pound to motor's weight.

Circle No. 203 on Reader Service Card.

ELECTROLYTIC LEVEL SWITCHES

New electrolytic switches produced by Corning Glass Works are arc-shaped gravity sensor devices made for both off-on and proportional control of missile directional systems.

Level and deviation from level are indicated within tenths of a degree by means of the switches. The switches are filled with an electrolyte which is said to give them six times less mass shift than mercury counterparts. Temperatures of up to 200°C can be withstood. Units are supplied in regular and subminiature sizes.

Circle No. 224 on Subscriber Service Card.

SILICON RECTIFIERS

Four new silicon rectifiers are being produced by the General Electric Co. Designated 1N1115, 1N1116, 1N1117 and 1N1118 the new units are stud mounted. Voltage ratings for peak inverse conditions are 100, 200, 300, and 400 volts with a maximum rms of 70, 140, 210 and 280 volts respectively.

They are designed for a maximum output of 600 ma at a case temperature of 150°C.

Maximum operating frequency for the units is 100 kc. They have a 10-32 stud for chassis mounting and are housed in a welded, all-metal case.

Circle No. 226 on Subscriber Service Card.

MINIATURIZED GYRO

Model 55,000 floated rate gyro has been designed by Norden-Ketay Corp. for missiles. A variety of maximum rate ranges from 1°/sec. to 1000°/sec. can be supplied. Accuracy better than ½% is

claimed while the gyro is subjected to severe missile environments.

Damping ratio is obtained without a heater by an arrangement that provides for verying the gap between the gyro rotor float chamber and an adjacent member. Damping ratio can be established to suit requirements of customers and maintained within 0.1 over a temperature range of —55°C to 85°C.

Circle No. 208 on Subscriber Service Card.

RADAR BEACONS

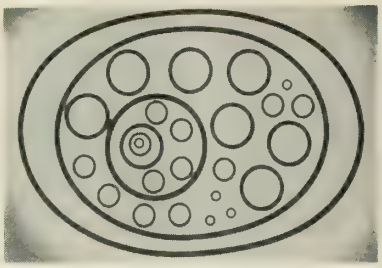
Avion division, ACF Industries, Inc. is producing four radar beacons for missile and aircraft use in "C", "S" and "K" bands. The pulse-type tracking aids respond to coded and uncoded pulse interrogations from radars. The "C" band unit delivers 100 watts and weighs 61 oz. The "S" band units deliver 2 and 1000 watts and weigh 51 oz. and 25 lbs. The "X"

band unit delivers 50 watts and weighs 59 oz.

The low power units operate from a self-contained transistorized power supply operating from batteries, and the large "S" band unit requires 28 volt dc.

Circle No. 210 on Subscriber Service Card.

ENVIRONMENTAL TESTER



New environmental chamber for testing rocket and missile components, principally for electronic testing and stabilization of metals, has a range of —125°F to 350°F Produced by Webber Corp.

The Model WE-3-125 has a pull-down time from ambient to —100°F of about 45 minutes, to —125° in about one hour, and will raise temperature from —125° to 300°F in about 15 minutes.

Unit capacity is three cubic feet and internal dimensions are 16 x 16 x 16 in. Overall measurements are 28 in length, 32 in. width and 66 in. height.

Circle No. 201 on Reader Service Card.

"O" RINGS

A new line of red silicone rubber "O" rings designated Style 9599 has been announced by the Garlock Packing Co. of Palmyra, N. Y. The new rings are manufactured from 70 durometer hardness stock exhibiting low shrinkage and compression set.

The "O" rings, available in standard AN sized, are recommended for dry heat service on which synthetic rubber compounds and natural rubber do not maintain their rubber characteristiccs. The silicone rings resist oxidation, withstanding indefinitely continuous exposure to hot air and temperatures up to 300°F, and in most applications will withstand for long periods of time, exposure to dry heat at temperatures from 300°F to 500°F.

Circle No. 211 on Subscriber Service Card.

SILICON TRANSISTORS

Texas Instruments, Inc. has announced the recent addition of fifteen new silicon transistors to its line of high temperature devices and brings to 36 the number of such units currently manufactured by the company.

All of the new units are in round cases and are designed for production by automatic techniques in addition to meeting military requirements.

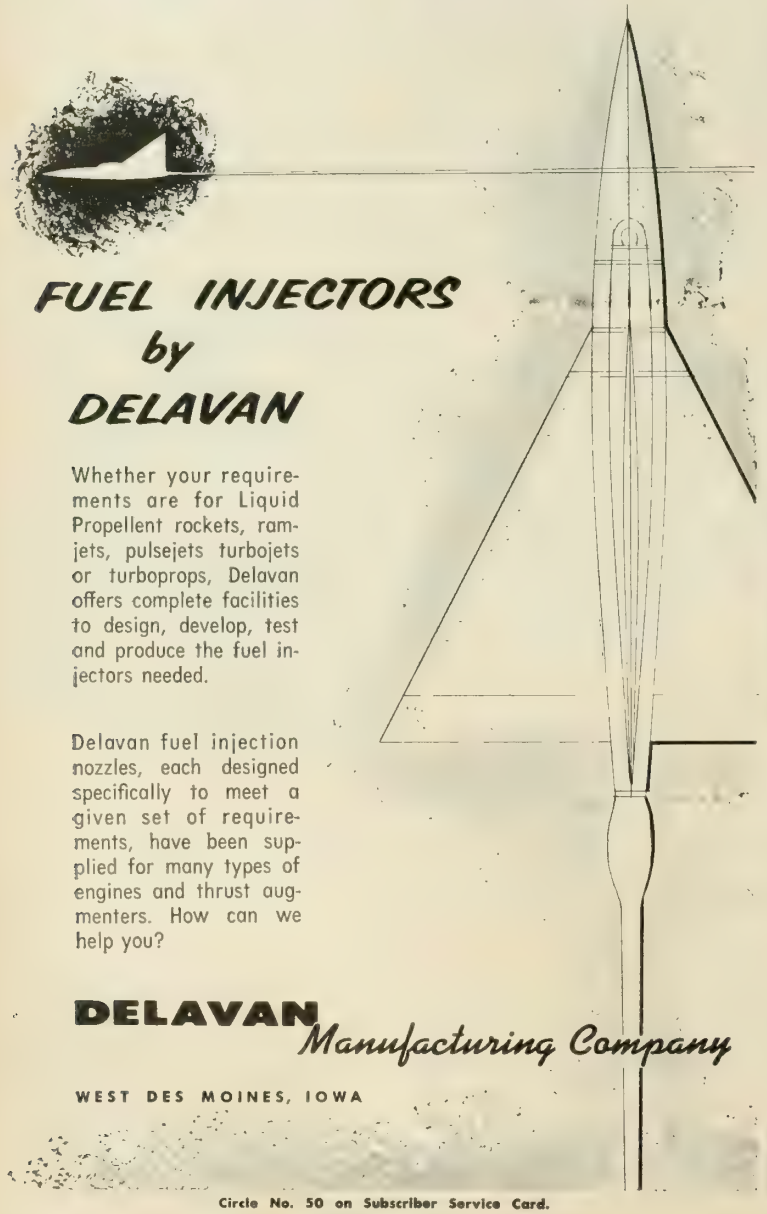
Three years ago the company introduced silicon transistors which are ideal for military use because they operate stably at temperatures up to 150°C.

The new line includes two switching transistors, tetrodes, medium power types and five small signal units.

Circle No. 204 on Subscriber Service Card.

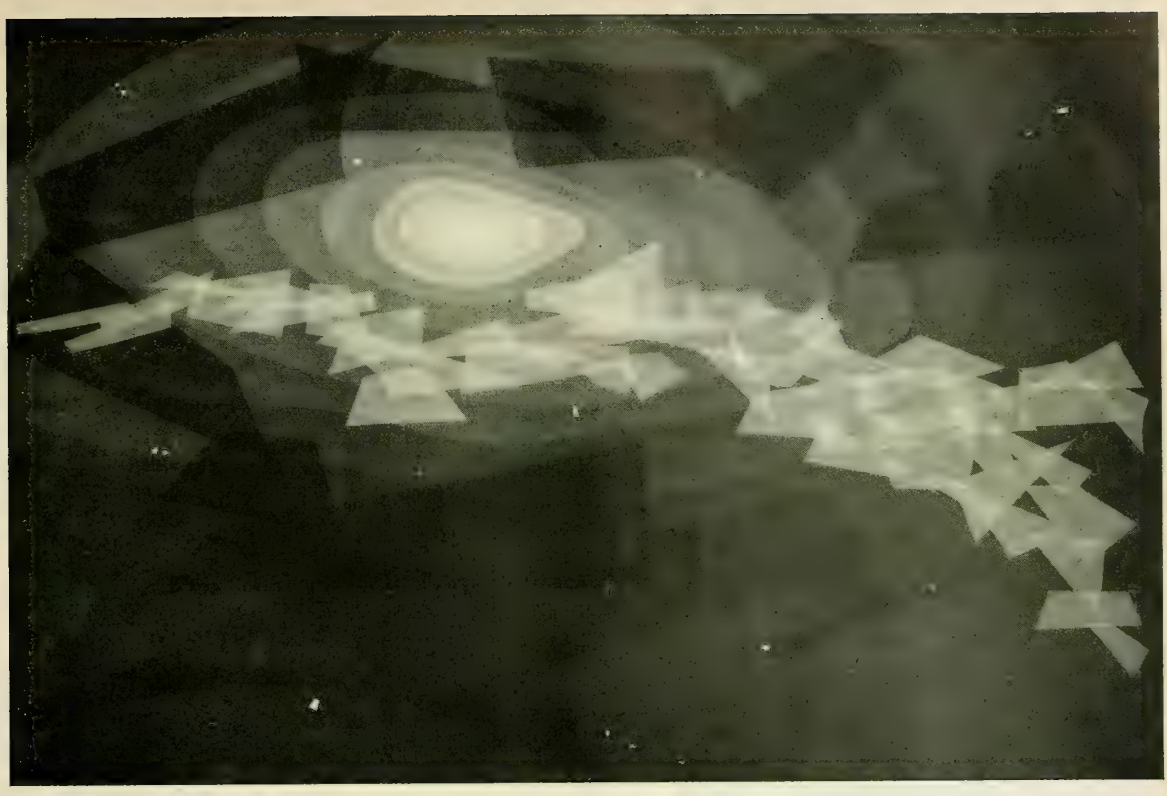
THROTTLING VALVES

Greer Hydraulics, Inc., has developed a series of precision throttling valves which are adaptable to a variety of installations. The series is designed for use with oils, fuels and other liquids compatible with aluminum and steel in central hydraulic systems, missiles systems, and test equipment. They also can be provided in other materials for use with water, acids and other corrosive liquids.



Featuring low torque, the valves are available with 2", 1½" and 1¼" ported flanges adaptable to one basic body size; and 1", ¾", ½" ⅜" and ¼" ported flanges adaptable to another basic body size. Valve body can be removed without breaking the line, and valve seat replacement can be made without removing body from line.

Circle No. 215 on Subscriber Service Card.



ACCELEROMETER

Genisco, Inc., has made design changes in its Model GMO Accelerometer which make it particularly adaptable for use in guided missile flight control systems. The 8-oz., viscous-damped potentiometer-output instrument is available in ranges from ±2G's to ±30G's, hermetically sealed.

Specifications: Undamped natural frequency 15 to 40 cps; linearity within 1% of full scale from best straight line; damping 0.3 to 2.0 of critical; output resolution proportional to number of turns of

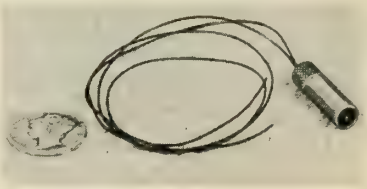
wire on the potentiometer, generally 0.34% of full scale; hysteresis generally less than 0.5% of full-scale output; potentiometer resistance 2 to 15K; power rating 2 watts; axis alignment within 1.0°; operational life 2 million complete cycles.

Circle No. 225 on Subscriber Service Card.

LOW G ACCELEROMETER

An accelerometer that measures values of g down to 0.03 has a minimum sensitivity of 40 millivolts per g. The Model 2218 unit has a natural frequency of 20 kc minimum and gives a response from 2 to 4000 cps with a linearity of 5 percent.



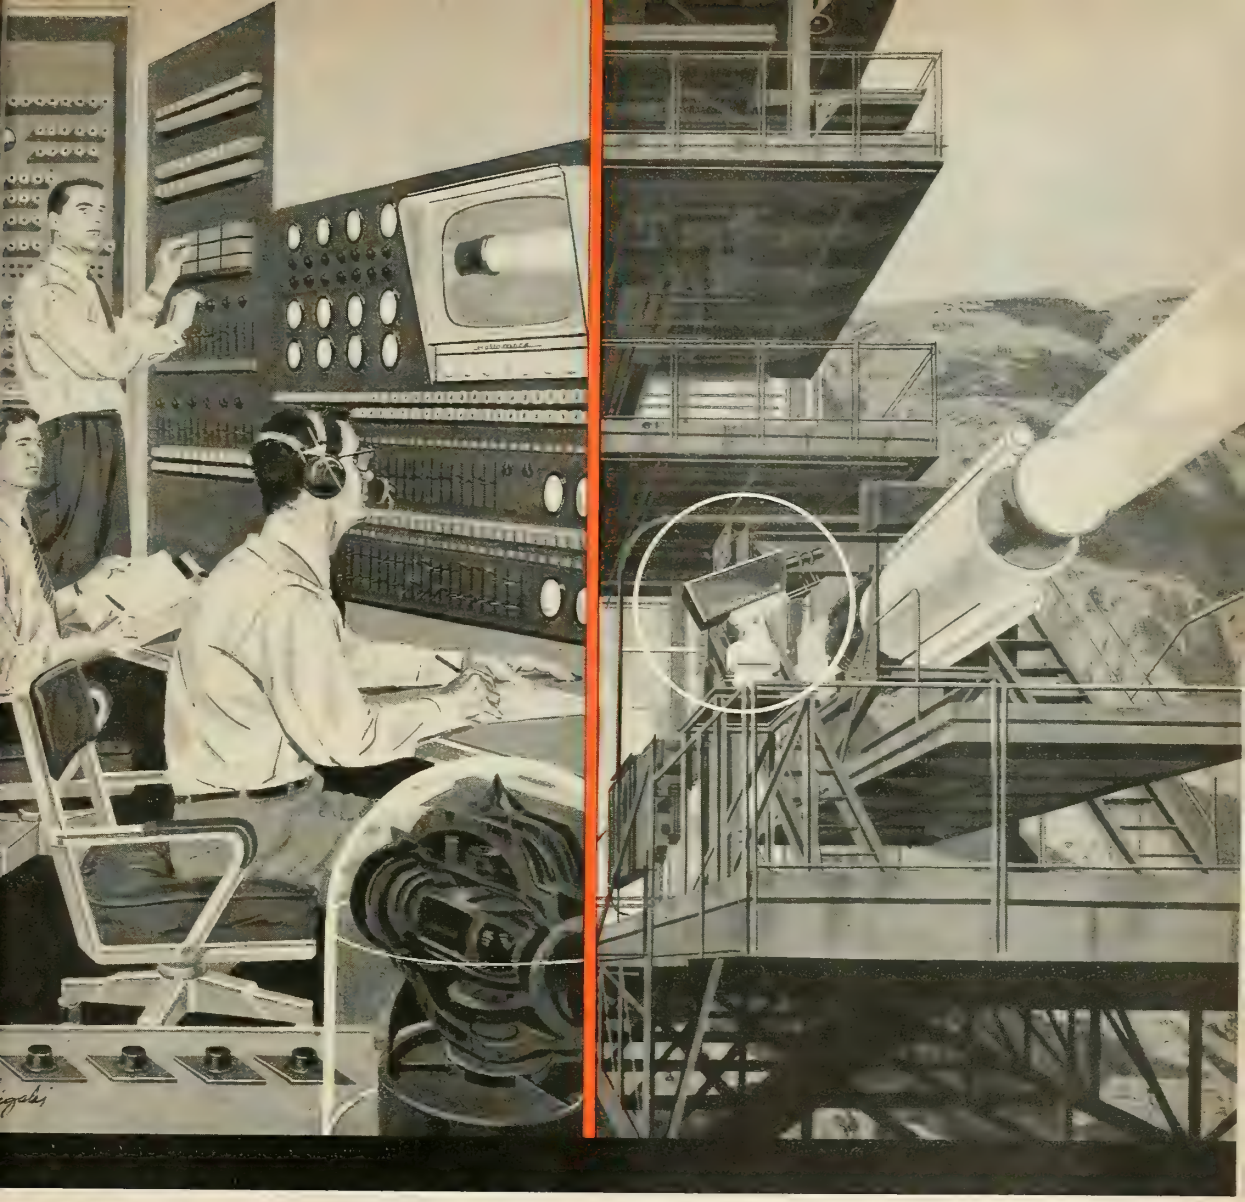
Response to high level noise is virtually eliminated by clamped crystal design and internal acoustic shielding. Temperature characteristic of the new unit made by Endevco Corp. is linear within 10 percent from —65° to 230°F. It weighs 2 ounces and is 1 inch hexigon in size.

Circle No. 221 on Subscriber Service Card.

SUB-MINIATURE TRANSDUCER

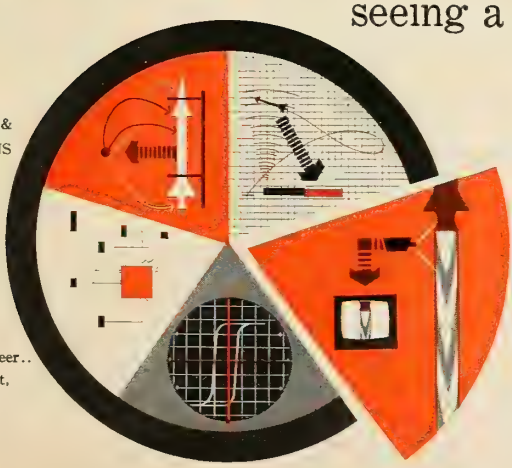
Electro Product Labs, Inc. has introduced a sub-miniature magnetic pickup that generates electrical signals from mechanical motion with physical contact. The unit weighs about 4 grams and is about ¼" in diameter.

The tranducer senses movement of ferrous objects and produces a signal proportional to the rate of movement. An Alnico magnet is used to energize the device.



Circle No. 230 on Subscriber Service Card.

VERTICAL GYRO



Waltham Watch Co is producing a vertical gryo Type WG-2 which provides accurate and reliable two-axis vertical reference data in the form of two synchro output signals.

The spin-axis is slaved to gravity by a gravity sensitive vertical reference device which supplies electrical control signals to torque motors which maintain the gyro spin-axis parallel to the gravity vector.

Vertical repeatibility is to within 10 min. of the arc cone and the initial erec tion from any standing position at any temperature from —55° to 71°C to within

seeing a hot one...on Hallamore captive TV

plus 30 min. of arc of vertical within 25 sec. after application of power. Altitude capabilities are unlimited and operating life is at 1,000 hrs. minimum.

Circle No. 200 on Subscriber Service Card.

PRESSURE TRANSDUCER

A pressure transducer being manufactured by Servonic Instruments, Inc. operates under vibration environments of 20g and temperatures to 400°F. The Model "H" transducer uses stainless steel sending elements that permit use of corrosive fluids in either gauge or differential models.

Case burst pressure is rated at 7500 psi and ranges from 1000 to 10,000 psig or psid are available.

Circle No. 206 on Subscriber Service Card.

DC GENERATOR

John Oster Manufacturing Co. has developed a permanent magnet dc generator which is said to have an unprecedented high output for its size and weight.

Type 13-PG-6901-01 has a 10-watt output at 10 vdc at 8,000 rpm continuous duty with 1,000-hr. life and 25°C maximum temperature rise. Diameter is 1.25", length 2.6", weight 7 oz., has 3 oz.in. input torque, face mounted. Designed for any dc generator application requiring exceptionally high dc output.

Circle No. 202 on Subscriber Service Card.

PERMANENT MAGNET MOTOR

John Oster Manufacturing Co. has unveiled a 1¼ in. permanent magnet gear reduction drive motor it believes is

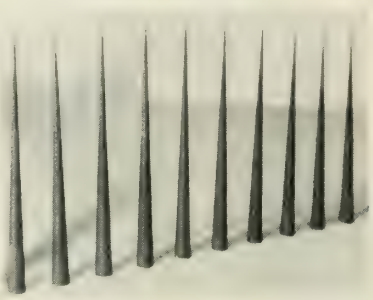
the first of its type and size to be provided with a brake.

The Oster unit combines motor, brake and gear train into a single unit. Design features include a reduction to 2.5° maximum of the coast of the output shaft from no load speed to 30 volts dc. No load output is five to 10 rpm at 24 to 30 volts dc and minimum stall torque is 30 oz.

Overall length of unit is 3.89 in. plus shaft and operating temperature range extends from —65° to 160°F.

Circle No. 232 on Subscriber Service Card.

COMPUTER INDICATOR TUBE



Amperex Electronic Corp. has announced a new Type 6977 filamentary subminiature indicator triode with fluorescent anode for visual monitoring of transistorized computers and other transistor circuits.

Heater voltage required is 1 volt at 30 ma ac or dc. The anode draws 0.6 ma from a 50 volt supply during 0-bias "on" conditions. A 3.5 volt signal is sufficient to cut off plate current and the light.

Circle No. 207 on Subscriber Service Card.

RF ABSORBER

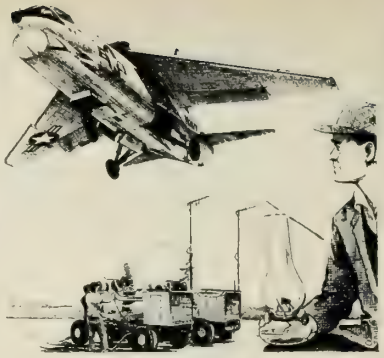
Emerson and Cuming, Inc., makes a series of plastic rod and sheet forms of Eccosorb MF plastic for waveguide and coaxial lines as absorbers, attentuators, terminations and loads over the entire microwave frequency bands.

The material is nonporous and needs no moisture protection on machined surfaces. It can be used up to 350°F. Suggested designs for both step and uniform tapers are available.

Circle No. 209 on Subscriber Service Card.

MISSILE SOLENOID

A miniature pull-type solenoid for missile applications which operates with efficiency and low plunger friction loss, has been developed by Carruthers & Fernandez, Inc.



Operating range —65° to 100°F. Solenoid provides positive, trouble-free operation on computing devices in missile components at high altitudes and speeds. Operating voltage from 6 to 100 vdc with plunger operating under side force of 8 to 10 g. At .3 amps, 100 vdc and 78°F, force is 1.3 lbs. with stroke .03". At same conditions force is .8 lbs. with stroke .06"; and .4 lbs. with stroke .125".

Circle No. 217 on Subscriber Service Card.

GAS COMPRESSOR

An oil free gas booster compressor, designed by Haskel Engineering & Supply Co., serves as a source of high-pressure, dry, uncontaminated helium or nitrogen for missile and test applications where gas cleanliness is of utmost importance.

The compressor uses a variable inlet pressure source and is operated without lubrication. It delivers outlet gas pressures from 6,000 to 10,000 psi with average capacities from 10 to 20 scfm using inlet pressure sources between 500 and 2,200 psi. Compression is accomplished

FOUR OPENINGS FOR FLIGHT TEST INSTRUMENTATION ENGINEERS

Electronic Development Instrumentation Engineer. To conceive, design, laboratory-evaluate and test intricate components and assemblies aimed at automation of data acquisition and analysis. Requires Electronics or Physics degree and one to four years experience in electronics design.

Instrumentation System Design Engineer. To develop and coordinate over-all instrumentation system designs and measurement techniques for collecting data for any engineering field. Requires Engineering degree and one to four years related instrumentation experience.

Field Operations Instrumentation Engineer. To operate and add to an automatic data gathering and analyzing station containing telemetric and magnetic tape playback equipment. Electronics or Physics degree plus one to four years electronics design or test experience.

Lead Instrumentation Project Engineer. To direct over-all instrumentation system design for major aircraft series or model. Engineering degree and six years instrumentation experience.

A Vought Vignette

Soot Solved This Problem

One thing Richard (Rick) MacDonnell could say for flight test instrumentation — it had variety. Here he was, in line of duty, hunting a coal oil lamp on the Mojave Desert.

Looking back, Rick saw that the whole Crusader instrumentation program had been a series of shifting scenes. He'd started by talking to different specialists, finding out the kinds of flight information they wanted. He learned a lot about heats, loads, amplitudes and flutter. These were the things Rick's instrumentation would have to detect.

Designing and building the system took him in another direction. There was the airborne equipment — up to 12 miles of wiring and 600 pounds of black boxes for a single demonstration aircraft. Each sub-system was environment-tested, breadboarded, checked out and packaged to fit key corners of the Crusader structure.

Taking shape at the same time was a mobile ground station — another project with which Rick was associated. It brought flight test telemetering and data processing closer to automation than they'd ever been before. At Vought's Mojave Desert test base, Rick's equipment clicked. It speeded preparation for the Crusader's dramatic operational debut — the Thompson Trophy-winning speed run.

There was just one hitch — a National Aeronautical Association rule which would limit altitude deviation to 328 feet during the Trophy dash. A Bureau of Standards barograph would ride with the pilot, its stylus etching out exact altitude on a smoked cylinder. Fair enough — but Vought's desert crew didn't have a workable way to blacken duplicate cylinders for practice. And precise warm-up flights were essential.

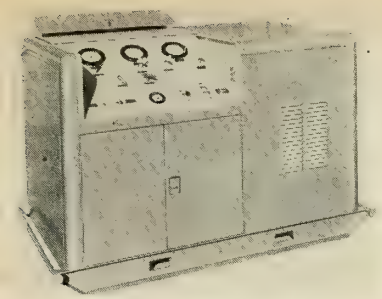
That's why Rick went hunting for a coal oil lamp. He found one in the store of a desert outfitter. Back on the base, the lamp was lighted and the wick turned up. It "sooted" the purpose perfectly.

Instrumentation means development adventure and variety at Chance Vought. Here, engineers of all specialties use initiative and self-expression to contribute to some of the most advanced instrumentation techniques in the industry.

CHANCE VOUGHT AIRCRAFT

All guided by Whittaker Gyros!

Unsurpassed for accuracy and dependability, Whittaker Gyros are able to shrug off the effects of shock, acceleration, vibration, heat or cold . . . yet continue to function as smoothly as they did in the laboratory!



THE REASON? For all the foregoing conditions, Whittaker Gryos have been *100% tested!* Overall customer rejection — month after month, year after year — is consistently less than 2%.

And because Whittaker uses nickel alloys in frames and gimbals, steel components are permitted. The result is added strength with very little increase in weight . . . and much more overall component stability.

Whittaker Gyros are designed by engineers and built by technicians who have worked together for more than a decade. This background and experience insure exact specifications the *first* time.

Whittaker Gyro

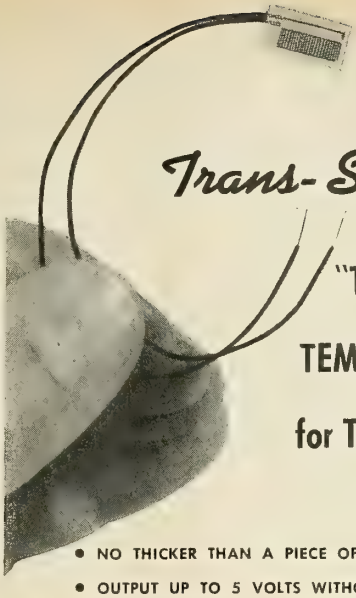
BROADBAND DISC BOLOMETER



Two new broadband disc bolometers, Models N603 and N603-4.5 covering the frequency range from 500 to 10,000 mc, have been developed by the Narda Corp.

The bolometers consist of two 100-ohm Wollaston wire bolometer elements mounted on a mica disc. An rf bypass capacitor is included for the ungrounded end of the device as well as a blocking capacitor at the central junction between the elements. The bolometers are manufactured for either 4.5 or 8.75 ma bias currents.

INDICATING PYROMETER

An indicating pyrometer made by Assembly Products, Inc. is available in 21 standard ranges. The units are medium resistance and have a maximum sensitivity when connected to one thermocouple of 300°F for full scale deflection. Standard ranges begin with minus 400°

NEW

Trans-Sonics*

"TAPE-ON" SURFACE TEMPERATURE RESISTORS

for Temperature Telemetering

- NO THICKER THAN A PIECE OF TAPE
- OUTPUT UP TO 5 VOLTS WITHOUT AMPLIFICATION
- AVAILABLE IN VARIOUS RANGES FROM −300° to +400°F.
- RESISTANCE CHANGE OF 100 OHMS OVER SPECIFIED RANGE
- NO HOLES TO DRILL — QUICK AND EASY "TAPE-ON" INSTALLATION

Trans-Sonics Type 1371 "Tape-on" Surface Temperature Resistors are precision resistance thermometers with a platinum resistance winding as the sensing element. These resistors which are no thicker than a piece of tape may be applied to *any surface* whose temperatures are to be measured. In a commutation circuit, they modulate standard telemetering transmitters without amplification. The new Type 1371 "Tape-on" Surface Temperature Resistors may be added to an installation using other Trans-Sonics temperature transducers without any further circuit modification. Each resistor is furnished with 6" long fibreglas-covered constantan leads. Write for Bulletin 1371 to Trans-Sonics, Inc., Dept. 9.

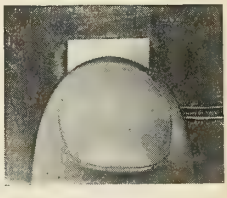
SPECIFICATIONS

SIZE: ¼" x 5/16"

Accuracy: ±2% of full scale range

Precision: ±0.5% of full scale range



Maximum Continuous Current: 20 ma rms (averaged over 1 second)

Environmental Operation Conditions

Vibration: 1" double amplitude, 0 to 22 cps ± 25g, 22 to 2000 cps

Shock: 100g in any direction, per paragraph 4.15.1 of MIL-E-5272A (10 milliseconds shock)

INSTANT INSTALLATION

As easy to apply as a thumb print.

For Transducers, See Trans-Sonics

Mixed Oxides are versatile, easy to handle

Propellant chemists and thermodynamic engineers seeking an oxidant uniquely suited to a wide range of rocket operating requirements find that Mixed Oxides offer these outstanding advantages:

Versatility — provides high specific impulse with many rocket fuels, including Triethyl-Trithiophosphate, Methyl Alcohol, 50% Ammonia and 50% Methyl Alcohol, 63% Triethylamine and 37% Orthotoluidine, Turpentine, Ammonia and Ethylene Oxides • **Freezing Point** — as low as —100°F, depending upon mixture • **Density** — compares favorably with other oxidants • **Easy Handling** — can be shipped, piped, stored in ordinary carbon steel • **High Stability** — non-corrosive, can be stored indefinitely in rockets maintained "at ready."

Mixed Oxides, containing 70 or 75% N_2O_4 and 25 or 30% NO, are economically available in large tonnages from Nitrogen Division's plant at Hopewell, Virginia, and for experimental purposes, in valved 125-lb. cylinders and 2000-lb. containers.

NITROGEN TETROXIDE (N_2O_4)
Oxidant for liquid rocket propellants

Molecular weight	92.02
Boiling Point	21°C
Freezing Point	—11.3°C
Latent Heat of Vaporization	99 cal/gm @ 21°C
Critical Temp.	158°C
Critical Pressure	99 atm
Specific Heat of Liquid	0.36 cal/gm —10 to 20°C
Density of Liquid	1.45 at 20°C
Density of Gas	3.3 gm/liter 21°C, at 1 atm
Vapor Pressure	2 atm at 35°C

PRESSURE VESSELS

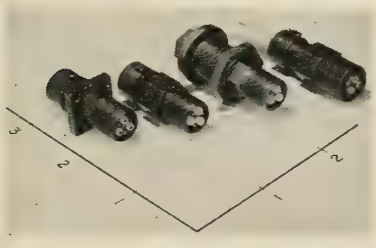
Spherical, high-strength pressure vessels for aircraft and missile applications, formed from titanium alloy or other materials, are available from Titanium Fabricators,, Inc.

Vessels range in size from 12-in. to 25-in. diameters and are formed by hot spinning hemispheres then joining with advanced welding techniques. Extensive research and development of the new welding and spinning techniques was sponsored by Convair-Astronautics.

Circle No. 248 on Subscriber Service Card.

CIRCUIT BREAKER

A circuit breaker line, designated Series AM17, which is interchangeable for 400 cycle, ac and dc use, has been developed by Heinemann Electric Co.



Designed primarily for aircraft circuits and airborne equipment applications, the AM17 can function either on 400-cycle ac or dc current without change in rating or essential time-delay characteristics. Series is manufactured in single-pole form only but can be readily linked to make two or three-pole companion trip units.

Breaker operates on hydraulic-magnetic principle and does not require derating for either temperature or vibration conditions.

HIGH-ALTITUDE CONNECTORS

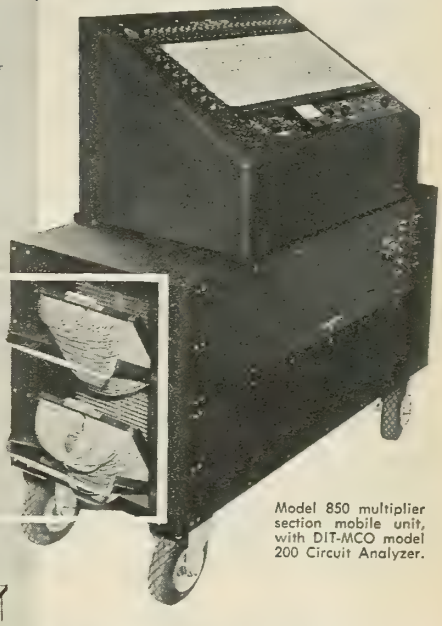
Three series of miniature high-temperature, electrical connectors which are

reported to have superior electrical characteristics have been introduced by Consolidated Electrodynamics Corp.

Designed for high-altitude operation. the major design feature is a staggered

from DIT-MCO Inc.

. . . another startling new development in automatic electrical system testing!



New Model 850

MULTIPLIER SECTION

featuring . . .

plugboard programming

new jumper-wire system simplifies test make-up and maintenance testing

Model 850 multiplier section mobile unit, with DIT-MCO model 200 Circuit Analyzer.

Now! In one operation at his desk, planner can design circuitry, layout matrix chart and jumper plugboard to conform to test sequence.

Now! Thorough, periodic maintenance tests can be made quickly and economically throughout the life of any airplane or missile.

Now! Test Modified Wiring Systems Without Altering Adapter Cables!

Do modified and improved electrical systems throw your testing section into a tailspin? Normally, it means existing test machinery (or the adapter cables, if DIT-MCO equipment is used) must be changed to conform to the circuit modifications. Here's how the new DIT-MCO plugboard system has solved that problem.

Circuitry can now be connected to the tester by the most convenient point-to-point method. Connecting wires (adapter cables) do not have to conform to any pattern. The testing sequence is programmed, quickly and easily, on the portable plugboards. Any subsequent circuit modifications are also handled on the plugboards . . . without changing existing adapter cables.

This is just one advantage offered by this new development. Write for full details on how DIT-MCO can help solve all your test problems.

Write today for complete information:

CENTURY MODEL 409D RECORDING OSCILLOGRAPH

Numerous agencies engaged in the manufacture and evaluation of missiles have turned to the Century Model 409D Recording Oscillograph as a reliable means of collecting missile performance and control data.

On-board mounting eliminates the necessity for the costly and often not reliable RF link.

The ruggedness and reliability of this 12-channel oscillograph have been demonstrated many times. One agency reports having recovered 42 satisfactory record rolls out of 43 firings. Another, using special mounting configuration, reports recording at 60 G's without damage.

This 13 lb. instrument is compact enough to be installed in most missiles and all electrical connections including remote control are accomplished through a single multi-pin AN connector.

Wire, Write or Phone

CENTURY ELECTRONICS & INSTRUMENTS, INC.

construction which gives long creepage path between pins despite small connector dimensions. Body is of anodized aluminum for corrosion resistance. Each pin of the mated connector is surrounded by Teflon.

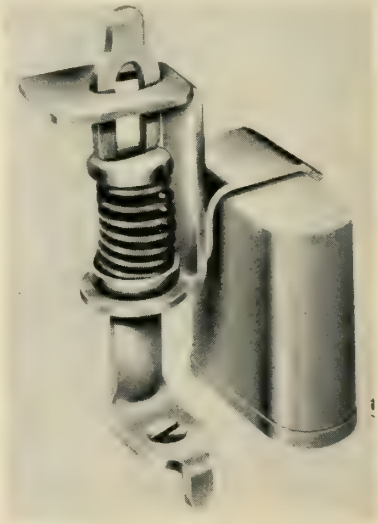
Design provides three separate seals—around entering wires, around each pin connection, and at the interlocking faces. This insures insulation resistance at 10^6 megohms.

Circle No. 228 on Subscriber Service Card.

RATIO TESTER

Allegheny Instrument Co., Inc., has introduced Model 11 ratio tester which can be used to measure dc voltage ratios in the range of 0 to 100% in aircraft and missile telemetering and measuring systems.

Wherever voltage or resistance ratios are more important than absolute values, Model 11 provides fast measurements to an accuracy of .05%.



Model 11 has self-contained mecury cell and standard cell and provides voltages in two ranges, 1 v and 10 v.

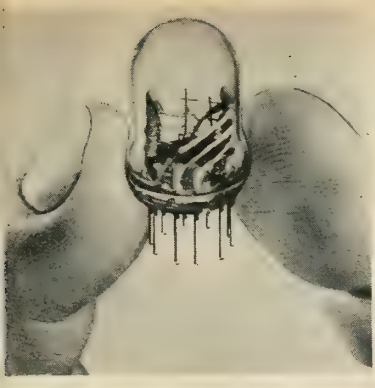
Circle No. 246 on Subscriber Service Card.

CRYSTAL CLIP

A line of crystal retainers made from type 302 stainless steel has been developed by Birtcher Corp.

Designed to hold nearly all popularly used crystals, semi-conductors and other miniature components having similar con-

figurations securely in place under severe shock and vibration.



Chassis mounting is accomplished through one screw or rivet and a drilled hole for a positioning tab. Removal of crystal is done through slight upward pressure on the spring-loaded retaining flange which swings out of the way for easy access.

Circle No. 234 on Subscriber Service Card.

MINIATURE READ-OUT TUBE

A miniature, all-electronic device which converts electronic signals directly to readable characteristics has been announced by Electronic Tube Division of Burroughs Corp.

Named miniature NIXIE, the unit is gas-filled, cold cathode, 10-digit, numerical indicator tube having a common anode. The tube utilizes 100 v and operates at

1/8 watt. It measures 6/10 in. in diameter, 3/4 in. high.

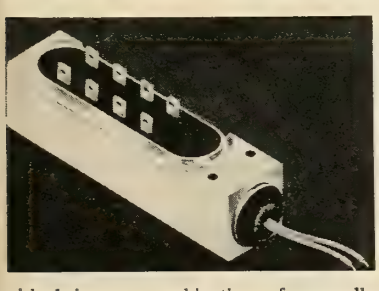
Features include rugged construction, simple plug-in stem, perfectly formed figures, controllable brilliance, according to the manufacturer. It is not affected by environmental conditions.

Can be used whenever read-out is required.

Circle No. 244 on Subscriber Service Card.

AUTOMATIC PROGRAMMER

Model 183 Programmer, developed by Sanborn Co., automatically programs operation of Sanborn six-and-eight-channel oscillographic recording systems for analog computer read-out.

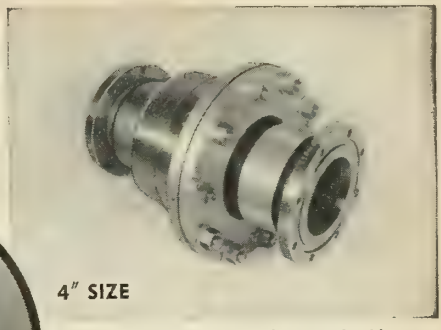


Joint operation of the 156- or 158-5490 Sanborn Console system and the Model 183 Programmer occurs automatically in the following sequence (unless manually terminated): Step 1: recorder turned on; Steps 2 to 16: calibration signal voltages of 0, 100, 20, 10, 5, 1, .2, 0, -.2, -1, -5, -10, -20, -100 and 0 fed to all channels; Steps 17 and 18; dc levels of computer read; Step 19: computer output recorded for predetermined chart length, or as controlled by computer; Step 20: recorder turned off, programmer reset for another cycle.

Circle No. 238 on Subscriber Service Card.

SQUIB-ACTUATED SWITCH

Atlas Powder Co. has developed a squib-actuated switch that has special characteristics attractive to designers and producers of aircraft, missiles and special weapons components.



Encased in metal housing, ½ in. x ½ in. x 2 5/32 in., the switch provides four sets of contacts which can be furnished in any combination of normally open and normally closed positions. It is unaffected by vibration of 100 g's amplitude from 20 to 2,000 cycles/sec. and is not damaged by shock acceleration of 15,000 g's in any direction.

Insulation resistance between open contacts at 500 v is 5 x 10^{11} ohms; contact resistance, closed contacts at 1 to 10 amperes, 4 x 10^{3} ohms; current capacity

Double sealing . . . inorganic construction make

New 'Diamond H' Series S Relays Doubly Dependable

in dry circuits

Separately sealed coils isolated from completely inorganic switches within their hermetically sealed cases make these new "Diamond H" Series S aircraft type 4PDT relays supremely reliable in dry circuits.

Physically and electrically interchangeable with "Diamond H" Series R relays, widely used in guided missiles, computers, jet engine controls, automation control systems and similar critical applications because of their broad range of performance characteristics, Series S relays will permit intermixing of dry and wet circuits safely.

Contacts are specially processed and cleaned before assembly; subsequent contamination from gases off the coil insulation is prevented by the coil seal. The switch mechanism has been simplified and is completely inorganic to eliminate other possible causes of malfunctioning.

Standard contact ratings include 30 V., D. C.; 115 V., A. C.; 2, 5, 7-1/2 and 10 A., resistive; 2 and 5 A., inductive, with special ratings available to 350 V., D. C., 400 MA, or other combinations including very low voltages and amperages, or amperages up to 20 for short life requirements. Coils are available with resistances of 1 ohm to 50,000 ohms. Operating time of 24 V. models is 10 ms. or less; dropout less than 3 ms.

Vibration resistances range from 10-55 cycles at 1/16" double amplitude to 55-2,000 cycles at 20 "G"; operational shock resistances to 50 "G" plus, and mechanical shock resistance up to 1,000 "G". Nine standard mounting arrangements, plus a ceramic plug-in socket, are available. The unit displaces only 1.6 cubic inches, excluding terminals.

"Diamond H" engineers will be happy to work out a variation to meet your specific requirements. Tell us your needs . . . or write for bulletin on new "Diamond H" Series S relays.

of contacts, continuous, 10 amperes; for 100 millisecond, 100 amperes. Actuation time of switch: carbon bridge, less than 1 millisecond; wire bridge 2-4 milliseconds.

Circle No. 247 on Subscriber Service Card.

DIGITAL TACHOMETER

A digital tachometer offering precise rotational measurement for instrumental applications for missiles is being manufactured by Nacimco Products, Inc.

Accuracy of the instrument is limited only by read-out method employed, and can be better than .001 rpm, with a scale of zero to 10,000 rpm. Output can be by sharp pulse or sine wave with signal set one to 100 per revolution. The tachometer is available with either single-ended or

feed-through shafts, for mounting on drive pads.

Instrument is said to be extremely rugged and has proven highly reliable in wide a range of applications.

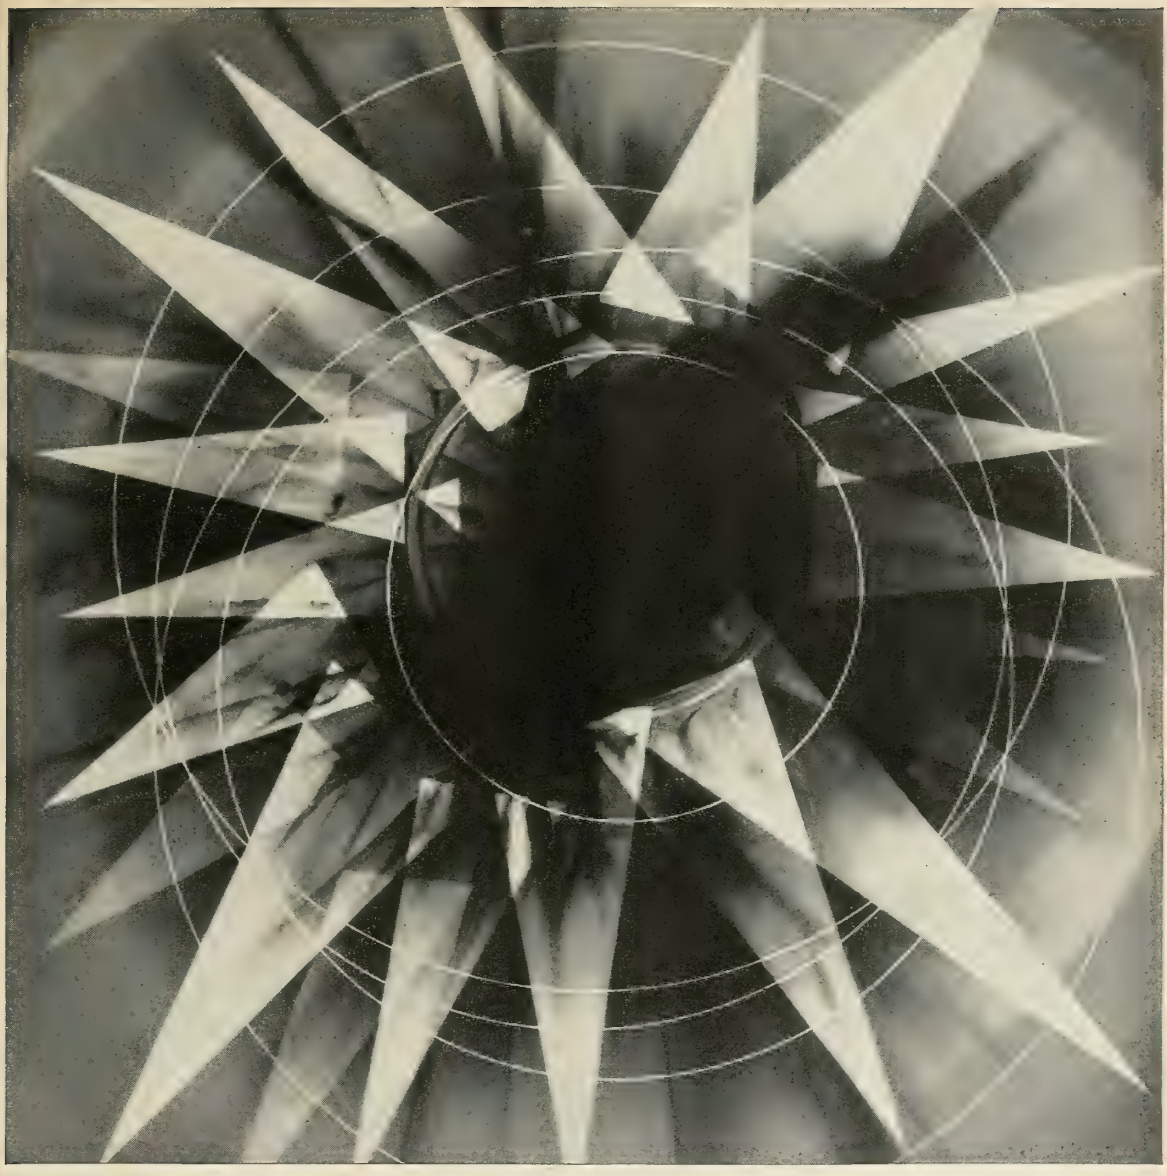
Circle No. 245 on Subscriber Service Card.

SILICONE BLANKET

Hewitt-Robins, Inc., has developed a 6 ft. x 30 ft. silicone blanket for use in high temperature vacuum bonding of epoxy resins. Blanket will permit bonding of larger surfaces than previously possible.

Blankets are made in standard thicknesses of 1/16 and 5/16 in. but can be made in heavier gauges on special order. They can withstand operating temperatures up to 500°F and have good heat aging properties, high tear resistance, high elongation, high tensile characteristics and good recovery.

Circle No. 243 on Subscriber Service Card.



SILICONE RUBBER

Two silicone rubbers have been developed for service at temperatures in the range of 600°F by Dow Corning Corp.

Identified as Silastic 6535 and Silastic 2071, both are said to be primarily cloth-coating stocks, characterized by excellent bond strength, low compression set, and a high degree of resistance to reversion under clamps.

Silastic 6535 is a liquid dispersion type. Vulcanized, it retains resilience from 600°F to -178°F.

Silastic 2071 is designed especially for calendering, although it is also suitable for molding or extruding. Properties

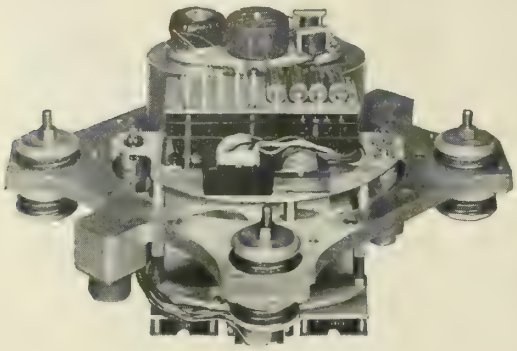
breaking the barriers
with Utica Vacuum Metals

Now that supersonic flight has become routine, today's challenge lies in developing *metals* and *means* of cracking the thermal barrier.

The metals problem has already been partially solved by superalloys produced through Vacuum Melting. This process, as developed by Utica, has yielded such super refractory alloys as Udimet 500—a clean, pure alloy combining unsurpassed stress-rupture life with superior high tensile strength in the 1200° F to 1800° F range. *At 1600° F, Udimet 500 has a tensile strength of over 100,000 PSI.*

In addition to the development of new and superalloys, Utica specializes in upgrading the quality of existing alloys.

VACUUM MELTING
provides these properties



- High temperature corrosion resistance
- Increased ductility
- Extreme cleanliness
- Precise chemical control
- Longer stress-rupture life
- Increased tensile strength
- Better fatigue resistance
- Greater yield strength
- Greater impact resistance
- Greater creep properties

UTICA DROP FORGE & TOOL DIVISION — KELSEY-HAYES CO., UTICA 4, NEW YORK

SCIENTISTS AND ENGINEERS:

DESIGN ADVANCED AIRBORNE CONTROL SYSTEMS LIKE THIS!

BRAINS FOR THE VANGUARD ROCKET DESIGNED BY HONEYWELL AERO!

Here is the first photograph of the guidance reference system for Project Vanguard. Designed and built by Honeywell Aero, this sensitive electronic mechanism must keep the finless rocket on course despite vibrations and accelerations hitherto unknown.

Many of the components of this Vanguard Guidance Reference System have possible inertial applications.

And Honeywell's development of precise gyros, accelerometers and computers makes Honeywell the leader in this advanced new field of inertial guidance.

FUTURE ACCOMPLISHMENTS! Inertial guidance is just one of the many exciting areas in which Honeywell scientists and engineers are making new advances. 280 research and development projects now in progress are in such fields as:

Inertial Guidance • Flight Control Systems • Liquid Measurement Systems • Vertical, Rate and Integrating Gyros • Digital and Analog Computers • Jet Engine Controls • Air Data Computers • Bombing Computers • Transistor Amplifiers • Instrumentation.

Career Opportunities: Each of these projects offers exceptional career opportunities for capable engineers and scientists.

And, at Honeywell, your advancement will be aided by these factors: *Honeywell Aero is growing;* Engineering personnel, tripled since 1951, is still growing faster than the avionics industry average. *Honeywell engineers work in small groups;* you guide your own development team, supervise your own project. *Honeywell Aero is engineer-managed;* supervisors understand your problems, know your value, help you move ahead.

WRITE TODAY!

For more information concerning these opportunities or for a personal interview, send your résumé to: Bruce D. Wood, Technical Director, Dept. TA19D, Honeywell Aero, 1433 Stinson Boulevard, Minneapolis 13, Minnesota.

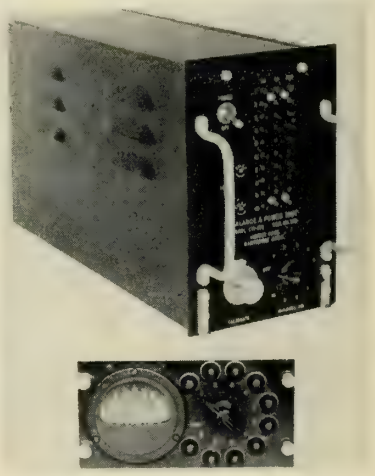
HEAVY-DUTY CIRCUIT BREAKER

A weatherproof, precision-type, heavy-duty circuit breaker for applications demanding precision, high shock and vibration resistant units, is in production at the Spencer Thermostat Division of Metals & Controls Corp.



Breakers weigh 7½ oz., are compact and have snap-acting disc actuating elements. Ratings range from 105 to 200 amperes.

Automatic and manual reset types operate at predetermined current overload. Excess current passing through the disc causes it to heat to tripping temperature and snap into reverse curvature, opening the contacts and breaking the circuit. In automatic reset types, disc reverts to original curvature after short cooling time.

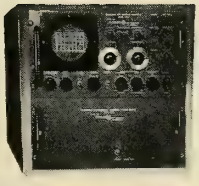
DYNAMOMETER

Development of a dynamometer to completely test torque and speed characteristics of shaded pole motors and induction motors has been announced by Magtrol, Inc.

The unit operates on the principle of feed back torque control such that when a decrease in speed is detected by the tachometer generator of the unit, a corresponding decrease in load torque is instantaneously effected and the motor stablilized in any portion of the curve. Motors may be tested for a maximum



PANORAMIC

TELEMETERING INSTRUMENTS

Use these proven Panoramic Telemetering Instruments *BEFORE, DURING* and *AFTER* tests to detect cause/effect of deviations, pinpoint difficulties, make corrections in time to avoid expensive system failures. The specific functions of these instruments in checking both the airborne and ground station equipment are briefly tabulated here.

provide a simple, reliable, almost instantaneous method of checking FM/FM Telemetering System operation

PANORAMIC TELEMETERING INDICATOR

MODEL TMI-1 Panoramic's Telemetering Indicator was specifically designed for checking FM/FM telemetering systems. In just one second it automatically provides a visual display of the frequency and amplitude of composite signal components. Scans spectrum logarithmically from 350 cps to 85 kc, or linearly, any 100 cps to 20 kc segment centered anywhere between 400 and 70,000 cps. Permits measurement of spurious products down 40 db. Features 20 db linear and 40 db log amplitude scales; 2 mv full scale sensitivity; automatic optimum resolution.

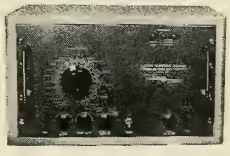
USES: Monitor entire subcarrier spectrum; measure and analyze subcarrier distortions; investigate hum, noise, microphonics and interference; detect channel spillover; set up subcarrier pre-emphasis; calibrate or linearize subcarrier oscillators (when used with Panoramic Frequency Calibrators); monitor magnetic tape re-recordings.

PANORAMIC ANALYZERS FOR RF SIGNALS

MODEL SA-3 Panadaptor, in three different types, is ideal as a tuning aid to permit rapid tuning-in of signal and detection of adjacent channel interference.

Type T-3000-CI is designed to operate with receivers having 21.4 mc IF.

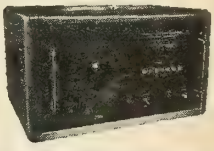
Types T-2000 and T-3000 are designed to operate with receivers having 30 mc IF.



MODEL SB-8b Panalyzor, in two different types, analyzes composite RF signal. Is used to set up deviation of RF carrier and to analyze sideband structure of FM'd carrier.

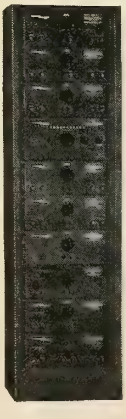
Type T-1000-CI is designed to operate with receivers having 21.4 IF.

Type T-200-R is designed to operate with receivers having 30 mc IF.



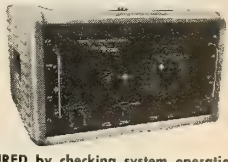
PANORAMIC TELEMETERING FREQUENCY CALIBRATORS

Three models, designed to meet the needs of different application requirements, provide precise frequency calibration points for all RDB channels conveniently . . . rapidly.



USES: Calibrate or linearize subcarrier discriminators; provide a precise frequency source for date reduction; calibrate or linearize subcarrier oscillators (when used with Panoramic Telemetering Indicator).

MODEL TMC-1 Panoramic's Telemetering Subcarrier Deviation and Three Point Calibrator sequentially furnishes upper limit, center and lower limit frequencies channel by channel. (Automatic switching with 20-second dwell per channel available on request.) Limits are ± 7.5% for all channels and ± 15% for upper five. Other limits optional. Frequency accuracy 0.02%. Built in channel selector automatically establishes proper center frequency and sweepwidth in companion Model TMI-1 to enable, through visual comparisons of subcarrier oscillator frequencies and corresponding calibrator frequencies, rapid set-up or check of maximum deviation limits and center frequency of subcarrier oscillators.



MODEL TMC-307 Panoramic's Seven Point Calibrator sequentially furnishes seven equally spaced frequencies per channel with an accuracy of 0.02%. End limits ± 7.5% for all channels and ± 15% for upper five channels. Other end limits and spacings can be furnished as required. Channel and frequency point switching may be either manual or automatic. On automatic, minimum dwell period is 10 seconds per channel.

MODEL TMC-211 Panoramic's Simultaneous Eleven Point Calibrator differs markedly from the TMC-1 and TMC-307 in that it provides 11 equally spaced frequencies having a 0.002% accuracy, for **all** channels **simultaneously** within the ± 7.5% or ± 15% limits. On automatic, switching of calibrating frequencies is controlled synchronously and cycling time is adjustable from ¼ to 8 seconds per frequency point. All channels can be sampled in as little as 2¾ seconds. Synchronization may be turned off and any channel calibrating frequencies may be selected manually. The instrument may also be remotely controlled through land wires making possible its use at a central station from which various subcarrier channels may be diverted to different locations.

PANORAMIC TELEMETERING CHANNEL SELECTOR

MODEL CHS-1 Panoramic's Telemetering Channel Selector is a companion instrument to Model TMI-1 automatically establishing the correct center frequency, sweepwidth and resolution of any of the individual subcarrier channels selected for display on the screen of the TMI-1. An internal signal switcher permits alternate display of subcarrier vs. external calibrating markers, available from the TMC-307, TMC-211, or other source, for visual comparison of linearity or spread of subcarrier.

sponse and capable of 2 full travel cycles/sec., or 10 cycles/sec. through any 10% portion of a full stroke.

Overall valve envelop is smaller than any unit previously available for full flow operation at high pressures. May be used with wide range of liquid or gas media.

Circle No. 237 on Subscriber Service Card.

PRESSURE-FILLED "O" RINGS

Development of pressure-filled metal "O"-Rings, which improve sealing characteristics at elevated temperatures and provide increased resilience with greater flange deflection, has been accomplished by Advanced Products Co.

Standard .010 stainless-steel "O" rings are filled with gas at various pressures ranging from 500 to 3,000 psi at room temperature. Internal gas pressure offsets the inherent loss of metal's strength at elevated temperatures.

Missile and other applications requiring operating temperatures above 1,000°F are principal uses for the rings. Rings are made with variations in pressure filling, silver plating, Teflon coating and use of special metals such as Inconel X to meet specific requirements.

TIME DWELL SERVO VALVE

Unit designed to convert electronic signals into control forces for missiles, drones or aircraft has been introduced by AiResearch Manufacturing division of Garrett Corp.

Weighing 1¼ lbs., the unit is known as a time dwell servo valve and serves as a link between a missile's electronic computer and control surface actuators. It converts electric signals into hydraulic forces.

Hydraulic oil flows can be regulated from 1/10 to 5 gal./min. at pressures from 750 to 4,000 psi.

A spool and body assembly controls quantity and direction of oil flow to an actuator and a torque motor converts electrical signals into forces to activate the valve spool.

MINIATURE PISTON-TYPE MOTORPUMP

Vickers, Inc., is producing a line of miniaturized motorpumps for use in missile systems.

Typical unit, Model AA-19054, delivers .84 gpm at 7,400 rpm and 1,000 psi. Hydraulic pump weighs 1 lb., and electric motor 7 lb. Overall length of both pump and motor is 9 15/16 in.

Starting torque is less than 10% over maximum running torque. High pump efficiency and low starting torque permit use of smaller, lighter motor. Pump

SUBMINIATURE!

Roll, pitch and yaw rate control gyros in one compact package weighing less than one pound!

United States Time Corporation offers the systems manufacturer the long sought after optimum performance/weight ratio in Gyroscopic Instruments. The 3-Axis Rate Sensor package achieves high performance in one third the weight and volume of previous rate gyros. Flight proven under severe environmental conditions, subminiature gyros and gyro packages can be supplied in production quantities to satisfy your specific requirements.

More than seven thousand of these precision-built rate gyros are currently in use.

U.S. Time's Research Staff and facilities are engaged in research, design and development directed toward new products and optimization of the performance/weight ratio in the following fields of precision instrumentation.

• STABLE PLATFORMS • FLOATED INTEGRATING GYROS
• ACCELEROMETERS • RATE GYROS • 2 AXIS GYROS • DAMPER SYSTEMS
• INERTIAL INSTRUMENTATION • GUIDANCE SUB-SYSTEMS

LEWIS WIRE PRODUCTS

HIGH TEMPERATURE CABLE...

Suitable for operating temperatures up to 650° with nickel-clad copper conductor and laminated insulation having superior dielectric strength and moisture resistance. In AWG sizes 22 thru 4/0. In accordance with MIL-C-25038.

ELECTRONIC HOOKUP WIRE...

Teflon insulated silver coated copper conductor with insulation in standard colors in accordance with MIL-C-16878.

EXTRA FLEXIBLE CABLE...

High Temperature and Moisture Resistant Electrical Cable. Lewis "EXFLEX" Cable, single and multi-conductor, superior for circuits on hinged or pivoted parts. Resistant to abrasion and temperaures to 500°F.

HEATING CABLE...

with nickel-chrome conductor and laminated insulation for operation at 500°F. extensively used by central stations to maintain proper temperatures in pipe lines exposed to wide variations in ambient temperature.

GLASS & ASBESTOS INSULATED HEATING CABLE...

with stainless steel braided shield for special high temperature applications, used by atomic energy facilities.

CUSTOM CONSTRUCTED CONTROL CABLES AND THERMOCOUPLE-WIRE CABLES...

with segregated circuits individually shielded, and with over-all shielding or with special shielding and jacketing.

FIRE-RESISTANT AND HIGH TEMPERATURE RESISTANT CABLE...

for circuits required to operate in 2000°F. flame for fifteen minutes. Excellent for fire-detector circuits and for use in temperatures up to 600°F.

THERMOCOUPLE WIRE AND EXTENSION WIRE...

in iron-constantan, copper-constantan and chromel-alumel to MIL specifications or in custom constructions. Twisted and shielded, cabled, shielded and jacketed. Multi-pair cables, shield and jacketed for missile applications.

RESISTANCE ELEMENT AND UNITS...

Core-wound flexible heating element and units for low wattage appliances as heating-pads, sealers, curling-irons, toys, wire marking machines, etc. Insulations of asbestos or glass or in combinations of both.

By utilizing and combining the various qualities of fire, heat, abrasion and moisture resistance of asbestos, glass, silicones and Teflon*, we have developed many special wires and cables for avionic and electronic applications. We invite inquiries for cables and wire constructed to customers' specifications for special applications.

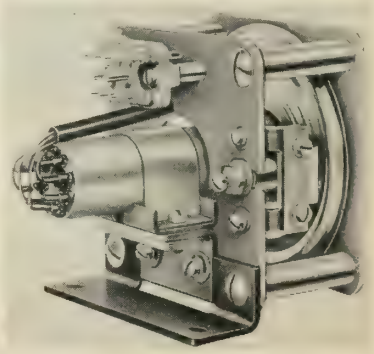
RECORDING SYSTEM

A Series 3,000 multi-channel magnetic tape recording system featuring a 300 kc band width is being manufactured by the Recordata Division of American Electronics, Inc.

Featuring unusual versatility, extreme accuracy, single switch for the selection of six speeds, and modular construction, the system is said to simplify all recording operations.

The system accommodates reels up to 14 in. as standard equipment and may be ordered to handle 19-in. reels. A single switch on the front panel selects any of the six standard speeds up to 60 in./sec. eliminating the need for changing of belts, pulleys, etc.



Tape transports are available which accommodate ½, ¼, or 1-in. tape. Tape guides may be easily interchanged. Backlighted control buttons, on the primary panel face, control high-speed fast-forward and rewind functions, record, playback and stop operations.

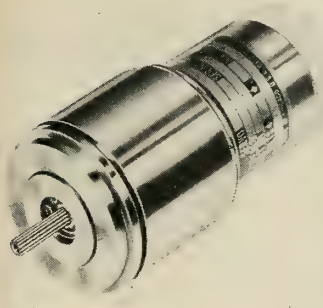
Convenient module housings provide plug-in facilities for record and playback amplifiers. By plugging the proper modules, instant selection of Direct FM or PDM recordings or playback in any combination can be achieved.

Circle No. 264 on Subscriber Service Card.

PRESSURE TRANSDUCER

Fischer & Porter Co. is producing a pressure transducer for use in data reduction systems. The device converts a 3 to 15 psi signal to ac millivolts directly propertional to pneumatic input.

When pressure is applied to the sensing element of the transducer, the results ing movement of an expandable capsule displaces an armature which induces opposing voltages in twin secondary coils. This voltage is linearly proportional to the pressure input. The output may be used



to position an indicator, recorder or control device. Accuracy of the F&P pressure transducer is high 0.25% of the full scale.

Circle No. 266 on Subscriber Service Card.

MOTOR GENERATOR

G-M Laboratories, Inc. has developed a new size 18 motor-generator in which the maximum rms null voltages are 13 millivolts total and 8 millivolts fundamental.

The motor and generator are the equivalent of the BOURD Mark 16.

Motor and generator are combined in an assembly having a single shaft. Motor has a diameter of 1.750 in. and is designed for operation on 400 cycles with a stall torque of 2.35 oz. in. Customary voltages are 26 v or 115 v on the fixed phase, and 26 v, 115 v, or 230 v on the control phase. Other voltages can be provided if needed.

The generator is 1.5 in. in diameter and is designed for operation on 400 cycles.

Circle No. 265 on Subscriber Service Card.

SHAFT POSITION TRANSMITTER

A highly accurate shaft position transmitter having infinite resolution and a null point at the center of rotation has been developed by engineers at G. M. Giannini & Co., Inc.

Designated Model 58175S-5, the instrument consists of a standard three-turn, slide-wire Spiralpot potentiometer which has incorporated within its case fixed resistors wired in a bridged circuit. One leg of the bridge is shunted with the variable section, and output can be read on a sensitive light beam galvanometer. Linearity over ±360° rotation is about ±0.11%. Over the entire ±540° range linearity is ±0.37% or better.

Physical configuration is identical to the Giannini Model 85175 Spiralpot which has a bushed mounted back anodized aluminum case 1.5 in. in diameter by 1.5 in. long. The precision ground, corrosion resistant shaft is supported in miniature ball bearings and an indexing pin provides for panel alignment.

Circle No. 260 on Subscriber Service Card.

SUB MINIATURE CONNECTOR

Automation-Engineering Corp. is producing a sub miniature snap-lock coaxial cable connector and mating receptacle in 50, 75 and 95 ohm sizes. Plug is spring loaded and snaps into position to engage special receptacle firmly. Plug cannot be removed by pulling on the cable, or by vibration, but only by sliding the knurled sleeve toward the cable end.

Connectors will withstand temperature range of —70°F to 550°F and shock of 100 g's on any axis. Vibrations at 5 g's from 10 to 20,000 cycles.

Lawmakers Censure Guided Missile Program

The military guided missile program is wasteful, duplicatory, poorly coordinated and badly managed, according to the Surveys and Investigations Staff of the House Defense Appropriations Subcommittee.

The staff submitted a 200-page report on the missile program to Subcommittee Chairman George Mahon (D-Tex.) at the outset of hearings on the Defense Department's request for $38.5 billion in new money for fiscal 1958. While the report itself was classified and therefore withheld from the record, a substantial portion of its findings were suggested by the questions of Rep. Mahon and his colleagues.

One of the principal things which apparently bothered the subcommittee's staff was the decision to go ahead with the Northrop *Snark* intercontinental missile while failing to request adequate support for North American's ramjet intercontinental *Navaho*.

"Our investigative staff has reported the Special Assistant for Guided Missiles (then Eger V. Murphree) termed the *Snark* program a questionable one," Mahon said. "The committee was advised that Gen. Curtis LeMay, Strategic Air Commander, under whose command the *Snark* will function, has frequently and consistently favored its cancellation . . . It appears to the committee that available dollars might be more profitably used for the more advanced weapons such as the *Navaho* . . ."

Reuben Robertson, Jr., former Deputy Defense Secretary, responded to the criticism with a stout defense of the *Snark*. He praised the accuracy of the turbojet missile, declared that it is firmly scheduled to go into operation with SAC and hinted that the *Navaho* will be dropped entirely. "We view the *Snark's* and *Navaho's* approach in the air-breathing intercontinental group quite similar to the *Thor* and *Jupiter* competitive situation," Robertson said. "One of them is going to win that race and should be put into inventory."

Other staff criticisms which filtered through the interrogation of witnesses:

1. The USAF *Bomarc* interceptor missile is overly vulnerable to jamming and is too expensive in relation to its contribution to national defense. (First production contract for the Boeing missile was announced last month.)

2. One of the outstanding weaknesses in the military missile program has been the failure of the Defense Department to have an adequate organization for the evaluation of military missile projects. Too little use has been made of the Pentagon's Weapon Systems Evaluation Group.

3. Duplication exists in many areas, including the *Thor-Jupiter-Polaris* IRBM program, the *Atlas-Titan* ballistic missile program and the *Nike Hercules* and *Talos* air defense program.

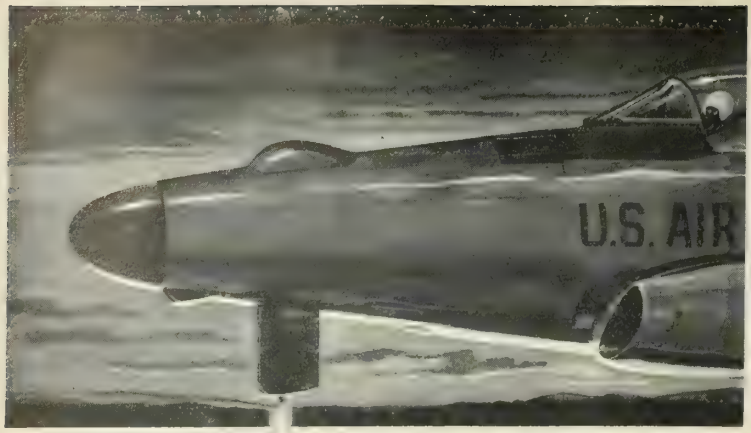
4. Efforts by the military services to establish anti-ballistic missile programs are not coordinated.

5. The Navy wasted millions on the Army's *Jupiter* IRBM before striking out on its own with the *Polaris* Fleet Ballistic Missile.

6. The *Nike I* is not an effective weapon and introduction of the *Nike Hercules* has been delayed through failure to utilize the Douglas Santa Monica plant as a prime source in addition to the Charlotte Ordnance Plant, also operated by Douglas.

The former Deputy Defense chief offered a rebuttal for most of the charges, plus some criticism of his own for the way the subcommittee's staff put together its report. Most of the duplications which now exist were ordered deliberately as insurance against technical setbacks, he observed. Exceptions are the Navy *Regulus* and the Martin *Matador*; latter was to be abandoned, but the decision was reversed when the Korean War developed, he said.

Robertson also said the staff was



A "confidential" presentation of the Air Force's overall missile procurement program for fiscal 1958 slipped into the published record of the USAF hearings. Reason for the security label was the fact that it included an exact breakdown of the ballistic missile program. Apparently it was overlooked by the censors when they cleaned classified information out of the record.

The figures show that almost half the total of missile procurement funds requested by the Air Force for next fiscal year will finance the *Atlas-Titan-Thor* ballistic missile development program. The airmen have programmed $955.7 million for the ICBM-IRBM projects, compared with $994.8 million for all other missiles. Included are comparisons with fiscal 1957 and 1956 (in millions of dollars):

	Fiscal 1958	Fiscal 1957	Fiscal 1956
Ballistic missiles	$676.9	$659.4	$267.0
Ballistic missile spares	37.5	15.7	11.6
Ground handling equipment	234.6	203.6	29.3
Center support	6.7	3.7	0
Subtotal	$955.7	$882.4	$307.9
Other missiles	737.9	1,016.4	551.8
Other missile spares	68.2	81.1	32.6
Ground handling equipment	188.7	188.9	105.1
Subtotal	$994.8	$1,286.4	$689.5
Total	$1,950.5	$2,168.8	$997.4

The procurement program does not include outlays necessary to provide contractors with the manufacturing, development and testing facilities they need for the ballistic projects. USAF is seeking $13,500,000 for these facilities in fiscal 1958, down sharply from the $84,500,000 voted last year and the $65 million voted in fiscal 1956.

Kentucky Windage at 650 MPH?

"Kentucky windage" is fine for an oldtime squirrel shooter at 60 yards. But how do you compute cross-wind allowance for high-speed jets aiming at fast-moving flank targets?

The compilation of firing tables required for cross-wind cannon firing is typical of the complex problems facing modern weaponeers. The special abilities of Thieblot Aircraft Company, a division of Vitro Corporation of America, in designing and manufacturing aircraft components and ordnance have made it a key member of the Army-Air Force team working on this difficult ballistics problem.

Thieblot's contribution was the design of a new ballistics data nose. Only a foot longer than conventional fighter noses, it carries a 20 mm. cannon with mount independent of the aircraft motion, four high-speed cameras, radar, and electronic equipment. With auxiliary ground controls this equipment "fixes" projectiles in time and space. This leads to greater protection for bombers and other combat aircraft through more accurate flank fire.

Thieblot Aircraft has also designed purge mat systems for jet trainers, a boundary layer control system, a nose-wheel steering mechanism, an inflight refueling unit, an escape reel for ditched aircraft and other equipment.

Like other divisions of Vitro, which specialize in atomic energy, weapons systems, extractive metallurgy and other advanced technologies of our new age, Thieblot makes tomorrow's technology available today.

arbitrary in its recommendations to cut off projects of many years' duration, that it gave undue weight to low-level staff studies as opposed to top policy-making points of view in its report, and that there is, despite all the talk of interservice rivalry, a rather extensive interchange of missile information between the services.

Here are the missile high-lights of the appropriation hearings:

Air Force

USAF is currently devoting its anti-ballistic missile efforts primarily to the task of early detection of the so-called "ultimate" weapon. Former Air Force Secretary Donald Quarles said the ICBM could be detected as much as 15 minutes before impact through modification of the SAGE system and the early warning radar lines. This scant warning could reduce casualties enormously as well as alert the armed forces to retaliation. The job of positive defense against the ICBM is much more difficult, and its creation would probably lag several years behind the introduction of the ICBM itself, Quarles said. He estimated the cost of an effective anti-missile defense as "comparable" to the cost of the ICBM itself. Maj. Gen. Bernard Schriever, chief of ballistic missile development for the USAF, underscored the difficulty. "There is . . . no doubt in anyone's mind that it (the anti-missile) is a very difficult technical problem, and that is only to take care of the most unsophisticated type of a ballistic missile nose cone."

Air Force will put money into at least two Navy airborne missiles. It will buy the infra-red *Sidewinder* air-to-air missile from the Bureau of Ordnance for its Lockheed F-104A day interceptor. It also expects to put the Navy-developed Martin *Bullpup*, an air-to-surface missile.

Procurement of the Douglas MB-1 nuclear air-to-air rocket will climb sharply in fiscal 1958. In addition to buying increased quantities for operational use, USAF expects to purchase more than $19 million worth of the weapons for its mobilization reserve.

USAF appears to have abandoned the idea of putting the Radioplane *Crossbow* (a derivative of the *Firebee* drone) into production. But two new drones, the Q-4 and Q-5, were revealed. Latter appears to be a derivative of the Lockheed X-7 ramjet test vehicle.

Navy

The Fairchild *Petrel* air-to-surface missile has been discontinued and will not be produced any further.

The *Vanguard* satellite launching

system is proving far more costly than the original $20 million estimate. Office of Naval Research has asked a total of $56.4 million for the project to date, including $25 million from the Pentagon Emergency Fund.

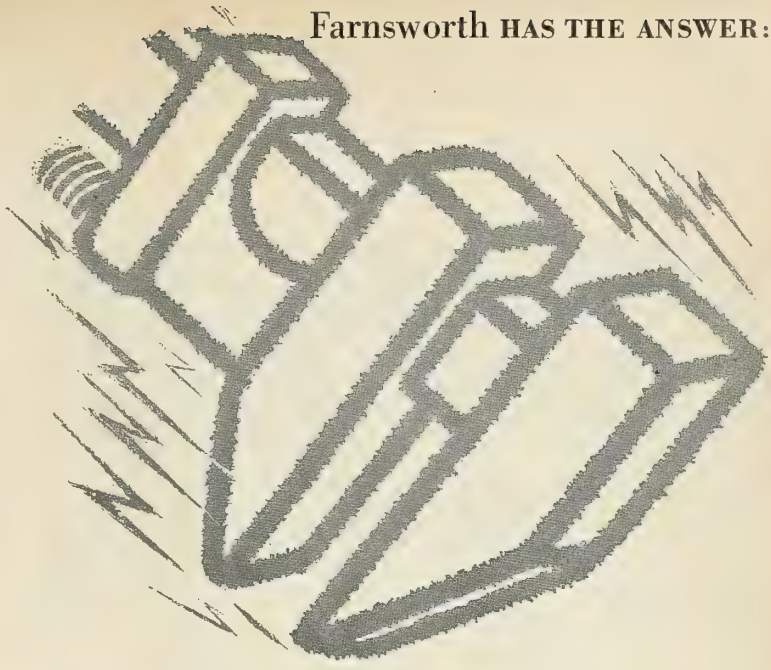
Bureau of Aeronautics is requesting $236,800,000 for procurement of missiles and drones in fiscal 1958, while BuOrd is requesting $179,332,000 for missile procurement.

For missile research, BuAer is asking $36,420,000 and BuOrd is requesting $128,300,000, including $68 million for *Polaris,* up $10 million from last year.

Rear Adm. William Raborn, Jr., director of the *Polaris* project, said the Navy's decision to abandon the fleet ballistic missile version of the Army *Jupiter* and proceed with independent development of the *Polaris* FBM will save U.S. taxpayers $500 million. He said the solid-propellant *Polaris* will be a cheaper, safer and better weapon for shipboard use than the liquid-propellant *Jupiter.*

Navy is also requesting $500,000 for advance planning of a nuclear submarine capable of launching the *Polaris* formal request for authorization to build will come next year.

A "major improvement" of the infra-red *Sidewinder* is under development and an improved version of the radar-guided *Sparrow* will go under development soon. Both are air-to-air weapons. A *Terrier II* is under development which will double the range of the present 20-mile ship-launched air-defense weapon.



The Marine Corps is contributing funds to the development of the Army's *Hawk* low-altitude aid defense missile. *Hawk* is an outgrowth of Raytheon's *Sparrow III.*

Two new air-launched weapons for use against submarines are in advanced stages of development, and production has commenced on one. A third new ASW weapon has just completed the research phase. The weapons were not identified, but it is believed one of them is the *Lulu,* a nuclear depth charge.

Army

Nike Ajax, the nation's first anti-aircraft missile to go into operational use, has been phased out. The soldiers canceled plans to buy the weapon with funds voted for the current fiscal year, and also dropped orders for 300 *Nike Ajax* placed with 1956 funds. They may drop another 400 *Nike Ajax* from the 1956 program. The money is being diverted to the more advanced *Nike Hercules,* with procurement of the latter transferred from the Douglas-Santa Monica plant to Charlotte Ordnance

Farnsworth HAS THE ANSWER:

How to throw an

Electronic

Monkey Wrench

Attack . . . counterattack . . . offense . . . defense— for every tactical movement there must be an effective answer. That is why we must be able to employ a defense that literally "throws a monkey wrench" into the enemy's operations.

Our very survival may depend upon what is known to the military as—countermeasures. These embrace most of the sciences; they call for vast knowledge, many skills and unlimited imagination . . . in the use of radar, infrared, microwave, and other techniques.

Farnsworth scientists and engineers have these abilities and facilities . . . that is why they have been selected to devise, test, and produce various electronic countermeasure systems and equipment that will confuse, stall, and stop the enemy.

Plant to build up production there as rapidly as possible.

Funds have been requested to support development of the *Talos* during fiscal 1958. This is the shore-based version of the Navy-developed air defense weapon transferred from the Air Force to the Army in the same Pentagon order last November which gave the *Jupiter* to the Air Force. The Army plans to evaluate *Talos* as a possible supplement to *Nike Hercules*.

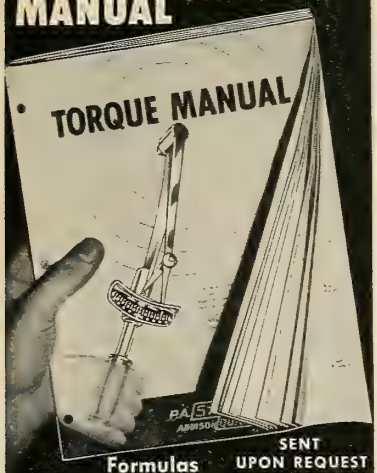
The Army has given top priority to the development of an anti-ballistic missile. It has requested $12 million to finance study of the problem in fiscal 1958. "We must get on with the job," declared Lt. Gen. James Gavin, chief of Army research.

Corrosion and deterioration have taken their toll of *Nike Ajax* now installed at launching sites. Army is asking funds to rebuild some 4,000 of the weapons. Nitric acid and exposure to the weather have been the chief troubles, but synthetic rubber components like gaskets have also shown signs of deteriorating.

Solar Furnace to Aid Missile Metal Studies

The study of the effects of rapid temperature changes on metals used in missile structures is expected to make the greatest use of a huge solar furnace to be constructed by Air Research and Development Command near Cloudcroft, New Mexico.

The furnace will be the largest in the world and more efficient than the existing one in the Pyrenees Mountains between Spain and France. Completion is scheduled for early 1959. Use of the instrument will be under ARDC'S Holloman Air Development Center.



The new furnace is expected to produce temperatures as high as 8,000°F—about 70% that at the surface of the sun. A staff of about 100 will be needed for its operation.

The furnace will be composed of three basic parts: a heliostat, which is the primary sun-reflecting mirror, measuring 130 ft. high and 140 ft. wide; the attenuating shutter, a venetian blind-type device which regulates the amount of sunlight traveling from the heliostat to the parabolic mirror; and, the parabolic mirror which collects the sunlight and concentrates it on the focal spot.

Thiokol Gets Contract

Thiokol Chemical Corp. has received a $790,758 contract for solid-propellant boosters for the Martin *Matador* TM-61B. Work will be done at company's Utah Division at Brigham City.

industry briefs

SIEGLER CORP. reports record sales of $22,688,892 for the nine months ending March 31. This almost doubles the sales figure for the comparable period in 1956.

RAYTHEON MANUFACTURING CO. has taken over management of Navy's plant at Bristol, Tenn., for production of *Sparrow III* missile for which Raytheon is prime contractor. Plant had been used by Sperry-Farragut Co. to produce *Sparrow I*, now in operational use.

THE GARRETT CORP.'s AiResearch Manufacturing division has started construction of a 40,000-sq.-ft. working area to consolidate electronic and pneumatic control activities at Phoenix. Master plan calls for 120,000-sq.-ft. building employing 500 workers.

THE MARTIN CO. has released 50 engineers and transferred another 50 from Baltimore to Orlando and Denver. Moves are results of Air Force cancellation of contract to develop high-speed bomber and failure of Martin to win contract for seaplanes.

BEECH AIRCRAFT CORP. will move its Boulder Division manufacturing operations to Longmont, Colo. Engineering and general offices will stay at Boulder. About 50 of division's 200 employes will move.

RETMA, Radio - Electronics - Television Manufacturers Association board of directors have unanimously voted to change the organization's name to Electronic Industries Association. Proposal will be submitted to membership.

McDONNELL AIRCRAFT CORP.'s employment reached all-time high with the recent hiring of the 25,000th employe. Current employment is five times World War II peak and weekly payroll now tops $2,600,000.

SUMMERS GYROSCOPE CO. is seeking Securities and Exchange Commission registration for 250,080 shares of $1 par common stock to be offered for subscription to current stockholders at rate of two new shares for each five shares held May 31, 1957. Proceeds will be added to working capital and used for general corporate purposes as needed.

RYAN AERONAUTICAL CO. has acquired an assembly plant and a 27-acre site adjacent to Torrance, Calif., Municipal Airport. New facility contains 137,000 sq. ft. of floor space.

AMERICAN BOSCH ARMA CORP. board of directors declared a dividend of 25¢ per common share, payable July 15 to holders of record June 14, and voted the regular quarterly dividend of $1.25 per share on the 5% cumulative preferred stock Series A and B, $100 par value, payable July 1 to stock of record June 14.

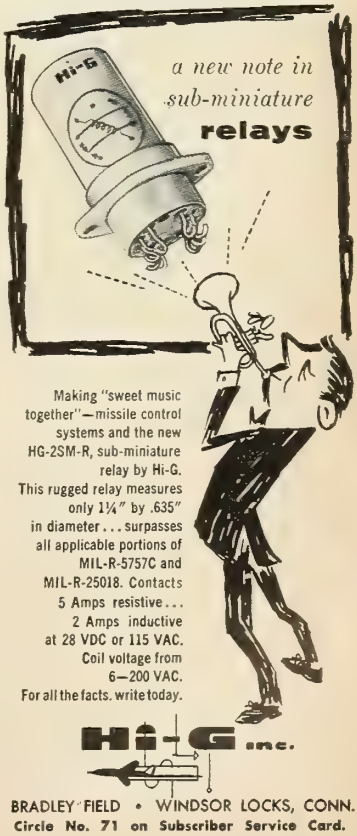
FIRESTONE TIRE & RUBBER CO. has received a subcontract from The Martin Co. to develop and test components of the *Matador* TM-61B missile. Work under the contract will be done at Firestone's Defense Research Division and Engineering Laboratory, Monterey, Calif.

RESEARCH ENGINEERING SERVICES CORP., Sandy Springs, Ga., is a newly incorporated firm of aeronautical engineers and research scientists in Atlanta. Principal officers are: president, Willi Jacobs; v. p., Peter Fielding; secretary-treasurer, Erik Sieurin.

*LOX GRADE KEL-F**

Unsurpassed resiliency at—320°F is offered in our especially processed Kel-F* for rocket and missile seals. Sheets and tubes to 18 inch diameter are available, exhibiting unusual clarity and a minimum of cold flow throughout the ambient range.

Our engineering department is available to work with you on your Kel-F* and TEFLON** problems.



We are approved to work under all military and commercial specifications.

KENTANIUM

2200°F CONTINUOUS OPERATING TEMPERATURES

5000°F LIMITED EXPOSURE

If any of your designs are grounded because your temperatures are too high for your materials—Kentanium* may be just what you need.

Kentanium is the name of a family of Titanium Carbides, developed by Kennametal Inc. It is molded from powders into many forms, retains strength and structural integrity at elevated temperatures, and possesses unusual resistance to thermal shock.

Engineers have reported successful use at continuous operating temperatures up to 2200°F, and under intermittent exposures up to 5000°F, where oxidizing atmospheres were combined with abrasion, and the parts were under compressive or tensile loading.

Many grades of this lightweight, exceptionally pure titanium carbide have been developed for various requirements. Kentanium can be extruded and molded into many forms, eliminating difficult machining. More intricate forms are readily machined from pressed slugs. Precise dimensional tolerances are attained by grinding after forms are sintered.

Kentanium is presently serving in bearings, thrust runners and other parts in pumps for handling high temperature liquid metals; blades, wheels, nozzle vanes, and temperature sensing elements for gas turbines and jet engines; bushings, seals and bearings (unlubricated); and other applications at high temperatures. Added information is offered in our bulletin "Kentanium." Send for it . . . and ask Kennametal engineers for added help if you need it to adapt Kentanium to your specific problem. Write KENNAMETAL INC., Latrobe, Pennsylvania.

*Kentanium and Kennametal are the trademarks of a series of hard carbide alloys of tungsten, tungsten-titanium and tantalum.

Industry Highlights

By Fred S. Hunter

They're back on the beam at Hughes Aircraft's Tucson plant, where the *Falcon* is produced. The five-day week (cut back to four last February) has been restored and most of the 496 employes laid off at the same time have been called back to their jobs. Moreover, Hughes-Tucson now has about 100 openings for workers having special skills. Reports that Hughes spent its own money in making fixes to restore the *Falcon* to its previous high degree of reliability are not confirmed by the company, but may very well be true. Hughes has never hestitated to do this sort of thing at its own expense. The Hughes *Falcon* now has a formidable competitor in the new Douglas MB-1 rocket. But Hughes has new models of the *Falcon*—the GAR-3 and the GAR-4—coming along, too.

•

Liquid oxygen has hazardous characteristics, such as its temperature of minus 297 degrees F, which can damage skin or eyes on contact, but rocket makers have found it creates no special problems if handled properly. At Rocketdyne, they handle it like water around the house—just try not to spill it—and they've never yet had a handling accident.

•

The Douglas MB-1 *(Ding-Dong)* has a tear-drop-like configuration incorporating four fins.

•

First Bay area headquarters of Lockheed's Missile Systems division is no more. It was opened in San Jose in February, 1956, with a handful of employes, built up to a maximum of 290, and diminished as space became available at Palo Alto and Sunnyvale. Lockheed closed its doors the other day after Building 102, the second 96,000 square foot structure at Sunnyvale, became available. The new Sunnyvale building also provided a home for members of the Navy's resident staff, who previously had occupied temporary quarters at Moffett Field. Capt. W. A. Hasler, Jr., formerly chief of the Navy office at the Army Ballistic Missile Agency at Huntsville, Ala., heads up the Bureau of Ordnance Technical Office providing field technical liaison and direction to Lockheed on what is known at Lockheed as the XN project, but which you know as the Polaris.

•

Highest Nike battery in the nation is in the protective ring of 16 guarding the Los Angeles area. It's at 6000 feet on Mt. Gleason.

•

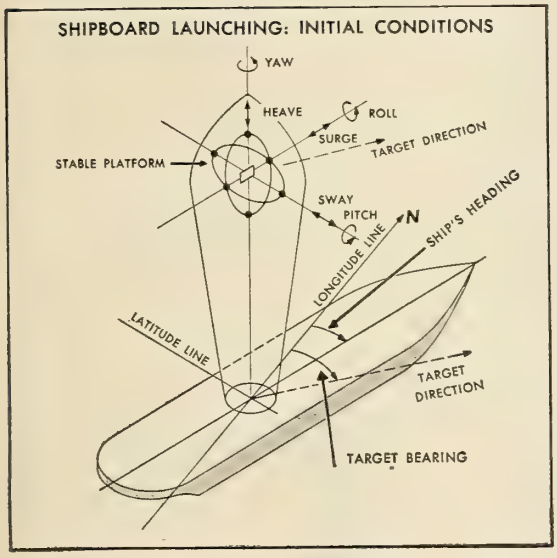
Northrop Aircraft, which has been paying $100 awards to employes for successful referrals of engineers, is now also paying $50 for referrals of needed machinists.

•

Willy A. Fiedler, now on the scientific staff of Lockheed's Missile System division, received a superior accomplishment award—with a $595 check to add to a $300 incentive award check previously received—from the Navy for a new-type dummy missile design he proposed while working at the Point Mugu Naval Air Missile Test Center. The design saved the Navy $300,000.

•

Every now and then Rocketdyne encounters an extra problem getting equipment into the back canyons of the Santa Susana Mountains, where its Propulsion Field Laboratory is located. A pressure vessel weighing 109 tons was a recent example. Took an entire day to haul it the 11½ miles from the Chatsworth rail siding. It also took two 250 hp diesel tractors in tandem. When the Rocketdyne crew tried pulling the low-bed semi-trailer carrying the pressure vessel with one diesel, the front wheels of the tractor were pulled off the ground. Heavy weight of the vessel, tractors and trailer was spread over 48 pneumatic tires.



ENGINEERS—SCIENTISTS

GENERAL ELECTRIC SELECTED TO DEVELOP GUIDANCE AND FIRE CONTROL SYSTEMS FOR NEW NAVY MISSILE, POLARIS

New Group Forming as Missile & Ordnance Systems Department of G.E. Adds Navy Project to Nose Cone Development Program.

POLARIS is the most challenging development undertaken by industry for the Navy since the nuclear propulsion program. It is an Intermediate Range Ballistic Missile, whose specifications call for launching capability from both surface vessels and submarines.

PROBLEMS UNIQUE IN MISSILE TECHNOLOGY

The diagram above presents the primary parameters involved in shipboard launching of a ballistic missile in its simplest form.

For Polaris, MOSD must not only surmount these initial conditions but solve fire control problems more complex than heretofore encountered. Pinpoint accuracy in missile guidance is an impressive accomplishment under the most favorable conditions. But how do you achieve it with a missile hurled from a moving platform and aimed at an object approximately 1,500 nautical miles away?

In addition, the Polaris guidance and fire control systems must also operate effectively under the difficult conditions created by submarine launching.

HOW IS MOSD EQUIPPED TO SOLVE THESE PROBLEMS?

As prime contractor for IRBM and ICBM Nose Cone Development, MOSD can draw on a reservoir of top level experience and skill. This G-E department also has a backlog of significant experience in the development and manufacture of Naval Fire Control Equipment, such as range-finders, computers and radar antennas.

NEW OPPORTUNITIES FOR ENGINEERS WITH EXPERIENCE IN THE DEVELOPMENT OF GUIDANCE & FIRE CONTROL SYSTEMS

A new group is now being formed to work on Polaris Missile Sub-Systems at MOSD. It will be located at Pittsfield, Mass. in the heart of the Berkshire resort and vacation area. Openings are at all levels for men with experience in:

GUIDANCE & ELECTRO-MECHANICAL COMPONENTS

Design, evaluation of guidance and fire control equipment

Design, development of electro-mechanical components and servomechanisms

Design, development, evaluation of inertial components, synchros, pick-offs, accelerometers, stable platforms, platform gimbals, verticals, etc.

Design, development, fabrication of analog computers for guidance and fire control systems

GUIDANCE & CONTROL SYSTEMS

Mathematical analysis, feasibility study of control systems and techniques

Synthesis, design, evaluation of guidance and fire control systems

Laboratory development, testing, modification of control systems

ELECTRICAL & ELECTRONIC COMPONENTS

Development of amplifiers and associated circuitry

Development, packing of electronic, magnetic, transistor servo type circuits and components

Reliability, evaluation, analysis of electronic circuits and components

Design, development of fire control consoles

Systems integration, design of electrical and electronic components

Development of electronic and solid state devices, semi-conductors, new transistor applications

OPPORTUNITIES OPEN ON OTHER MISSILE PROGRAMS

Engineers and Scientists with experience in other areas of Electrical Engineering, Aeronautical Engineering. Aerodynamics, Mechanical Engineering, Physics or Mathematics should inquire about positions on other missile programs at Missile and Ordnance Systems Department.

AN INVITATION

If you would like to contribute to any of the advanced missile development programs at MOSD, you are invited to send a resume of your education and experience. Or write us for a convenient application form. All resumes will be carefully reviewed by the MANAGERS *of our various technical components. You will be invited to visit our offices and discuss work we are doing directly with the Manager with whom you will be working. Communications will be entirely confidential.*

Please send resume to Mr. John Watt, Room 595-5

MOSD

MISSILE & ORDNANCE SYSTEMS DEPARTMENT

GENERAL ELECTRIC

1617 Pennsylvania Blvd., Philadelphia 3, Penna.

Curtiss-Wright Profit Up for 1st Quarter

Curtiss-Wright Corp. reports a consolidated net profit of $9,942,256 for the first quarter of 1957. More than 60% of these earnings stem from commercial business, it was noted by Roy T. Hurley, president and chairman.

Consolidated net sales for the same period were $147,427,760. Unfilled orders plus scheduled production under advanced contracts amounted to $147,427,760. A year ago, figures showed profits of $9,196,100 on sales of $132,641,353. Commercial business accounted for half the earnings in 1956.

NAA's Neosho Plant Producing *Thor* Engines

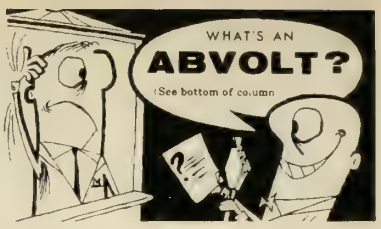
North American Aviation, Inc., has begun production of rocket engines at its Neosho, Mo., Rocketdyne plant following the receipt of an Air Force contract for a number of *Thor* IRBM propulsion systems.

Engines for *Thor* are in the developmental production at Rocketdyne's main plant at Canoga Park, Calif. Production at the Neosho plant will employ more than 1,500 persons by June 1958. About 650 of Rocketdyne's 10,000 workers are now at the Missouri facility.

Rocketdyne also is developing high thrust rocket engines for the *Jupiter*.

GE Adds Vermont Plant To Missile Systems

General Electric Co. recently has added guided missile production facilities to the Missile and Ordnance Systems Department.



According to MOSD General Manager George F. Metcalf, the production capability was added to supplement existing research and development capacities. The department has acquired existing GE facilities at Burlington, Vt., consisting of 400,000 sq. ft. and 1,600 trained employes.

Chief production items will include missile nose cones and arming and fuzing systems.

WDD Name Changed

Western Development Division of Air Research and Development Command has been renamed "Headquarters, ARDC, Ballistic Missile Division."

No changes in mission or organization were involved. The name change

was made to provide a more descriptive title in keeping with the expanded scope of Air Force responsibility in the ballistic missile field.

GE to Design *Polaris* Fire-Control System

General Electric's Missile and Ordnance Systems Department has been awarded a Navy contract for $1,500,000 to design and develop a fire-control system for *Polaris* mid-range missile.

Missile, which may be launched from surface ships or submarines, is built by Lockheed Aircraft Corp. Engines are solid-propellant rockets built by Aerojet-General Corp.

Convair-Astronautics Receives Work Assist

Convair-Pomona will give an assist of 50,000 hours of direct labor to Convair-Astronautics under terms of an inter-division work transfer agreement approved by the Air Force and Navy Bureau of Ordnance.

Pomona has nearly completed an earlier 75,000-hour engineering assist program begun last year for Astronautics Division.

EMPLOYMENT

DATA PROCESSING SPECIALISTS!

Get in now—at the beginning of the new era in missiles!

When you join Telecomputing's Engineering Services Division, you will be given full scope to allow you to grow . . . your talents will be used to the fullest . . . recognition and rewards will be yours as a matter of course.

Not only is Engineering Services a member of an integrated five-company missiles systems corporation which designs and manufactures its own data-processing equipment, but it is responsible for *most of* the data reduction of the integrated Holloman-White Sands range flight testing of all types of missiles including the newest developments in the field.

Fast Tax Writeoffs Granted Missile Firms

Douglas Aircraft Co., Sacramento, has been granted a certificate of necessity for accelerated tax amortization for a missile test facility in the amount of $2,455,600 at 70% by the Office of Defense Mobilization.

Other fast writeoffs for the missile industry include:

Tele-Dynamics, Inc., Philadelphia, telemetering systems for guided missiles, $203,575 at 70%.

Lockheed Aircraft Corp., Sunnyvale, Calif., research and development, $927,188 at 60%.

Lockheed Aircraft Corp., Sunnyvale, Van Nuys, and Palo Alto, Calif., research and development, $713,049 at 65%.

The Martin Co., Jefferson County, Colo., missiles, $110,000 at 60%.

Aerojet-General Corp., Sacramento, research and development, $945,000 at 60%.

The Martin Co., Denver, guided missiles, $108,296 at 65%.

Kansas Plant to Produce Boron Chemicals

Callery Chemical Co. has begun construction of a $3 to $4 million plant at Lawrence, Kan., for production of boron specialty chemicals for commercial use.

The facility is slated to begin production early next year and will employ 150 persons. It will consist of 11 buildings and four chemical processing areas. The plant is slated for a 200-acre site two miles north of Lawrence.

Callery is owned jointly by Mine Safety Appliances Co. and Gulf Oil Corporation.

Litton to Build Factory At Salt Lake City

Litton Industries is planning a 60,000-sq. ft. plant at Salt Lake City for manufacture of magnetrons, klystrons and other microwave tubes. The plant, Litton's 11th, is expected to employ about 600 people. No completion date has been announced.

Olin-Mathieson Sales Up, Earnings Down

Olin-Mathieson Chemical Corp. reports first quarter sales of $135,479,249 and net income of $10,009,979 compared to $144,340,677 and $10,080,099 last year. Earnings per share amounted to 75¢ compared to 76¢ at the same time in 1956.

engineers · scientists

WHICH OF THESE 18 CAREER POSITIONS at ARMA INTERESTS YOU MOST?

New long range projects assure not only challenging, high-level creative work, but security and job stability as well. Excellent starting salaries plus all the resort and cultural advantages of suburban Long Island living. Moving allowances arranged.

A partial listing follows. Further information on these and many more positions may be obtained by calling Robert Burchell COLLECT at PIoneer 2-0242.

MISSILE PROJECT ENGINEER
Coordinate project analysis, planning and controls including determination of project requirements and commitments in missile field.

ELECTRONIC SYSTEMS ENGINEER (Field Service)
Liaison with associate contractors and government agencies on inertial guidance system project. Must be thoroughly familiar with matters relating to digital and analog computers, power supplies, environmental conditions, housing and test facilities and test equipment.

FIELD EVALUATION ENGINEER
Perform overall planning functions for field evaluation of missile guidance systems. Direct activities in scheduling the field operations. Liaison with field test site agencies and formulating overall operating procedures at test site on missile project.

MECHANICAL DESIGN ENGINEER
Perform mechanical design of airborne instrumentation and transducers required for field evaluation of missile guidance systems. Responsible for packaging and mounting equipments.

FUNCTIONAL ENGINEERS — MISSILE SYSTEMS
Develop inertial guidance systems including gyro, accelerometers, integrators, servo systems and computers. Analyze functional problems arising during development and evaluation of said system.

OPERATIONAL EVALUATION ENGINEER
Perform engineering studies and analysis of techniques for evaluating performance of missile guidance systems and its components including gyros, accelerometers, digital computers.

PLATFORM ENGINEER
Conduct investigation of a theoretical nature relating to gyros or inertial platforms including design of closed loop control equipment pertaining to the above.

GYRO DEVELOPMENT ENGINEER
Develop precision gyro systems including mechanical problems such as lubrication, temperature controls, hydrostatics and vibration and electronic work on accelerometers, amplifiers, torquing circuits and electrical pickups.

OPERATIONAL ANALYSIS ENGINEER
Development work on evaluation of inertial guidance systems including in-plant and flight analysis of gyro systems. Development of measuring devices for precise determination of in-flight velocity, acceleration, altitude and position information.

RELIABILITY ENGINEER
Develop methods for evaluation of accuracy, reliability and operational suitability of missile guidance systems.

SYSTEMS EVALUATION (MISSILE GUIDANCE)
Perform functional engineering studies and design of inertial guidance systems, determine system and component requirements and performance, conduct system and component dynamic studies and simulation, perform error analysis.

PROJECT ENGINEER — PRODUCTION TEST EQUIPMENT
Administer and technically direct the program of design, development and manufacture of test equipment for production use in the manufacture, inspection, test and reliability control of highly complex electronic, electro-mechanical and gyroscopic equipment required for missile application.

GROUND EQUIPMENT ENGINEER
High degree of technical and administrative responsibility on complex projects involving the design and development of production test and field test equipment for gyroscopic systems and digital computers.

PROJECT ENGINEER — AIRBORNE EQUIPMENT
Guide and assist engineers in technical problems in field of electrical and electronic design, servo systems, missile guidance systems. Responsible for major product improvement program and test programs. Provide technical liaison with quality control. Heavy servo background desired.

ENVIRONMENTAL ENGINEER
To plan, conduct and report upon development studies of finishes, materials and processes, which will be incorporated into the design of electromechanical and electronic components and systems.

OPERATIONAL ANALYSIS ENGINEER
To plan, conduct and report upon environmental tests of electromechanical and electronic systems. Must be capable of redesigning components or systems to correct any deficiencies encountered during the evaluation program in the computer, servo systems and missile field.

QUALITY CONTROL ENGINEER
Require experience in gyroscopic trouble shooting. Design knowledge of stable elements and some background regarding reliability and failure association for complex guidance systems to be used in missile field. Must have complete knowledge of statistical methods.

GROUND EQUIPMENT ENGINEER
Plans and performs engineering studies, basic electrical and mechanical design, development and evaluation of production test and field test equipment where specific objectives and general requirements are known. Must be familiar with electromechanical instrumentation.

CALL COLLECT. Or, clip the job (or jobs) you're interested in and mail, with your confidential resume. No reference contact without your permission. You'll receive a prompt reply, and copies of "Your Engineering Career with Arma" and "Long Island," full of detailed information about this company and its community.

REACTION MOTORS UNVEILS NATION'S LARGEST ATTITUDE TEST STAND

ENHANCED CAREER OPPORTUNITIES FOR ROCKET ENGINEERS AND SCIENTISTS

RMI's new attitude test stand handles up to 1,000,000 lb. thrust engines in firing attitudes from vertically downward to 45 degrees above horizontal. It is just one of more than 20 special testing facilities for rocket engine development and production testing.

Some of the most advanced work in rocketry is going on right here in the East, at RMI's extensive test area in the heart of the beautiful Ramapo Mountains of New Jersey. Here the experienced rocket engineer or scientist has every opportunity for highest professional development.

Expanding from a broad base of past achievements through application of new concepts and outstanding new facilities, RMI is now working on highly classified developments that promise to establish the era of space flight sooner perhaps than anticipated by experts only a year ago!

Immediate openings exist for these high-level specialists:

PRODUCT ENGINEER (APPLICATIONS):

B.S. in M.E., A.E. or equivalent with a minimum of 5 years airframe powerplant experience. Your background should also include engineering and customer contact on technical products and services. You will assume responsibility for organizing a program to apply new and existing powerplants to all types of missiles. 2-3 days of your week will be spent answering inquiries and preparing proposals, the remaining 2-3 days traveling.

SENIOR DESIGN ENGINEER

Prefer M.E. or A.E. degree and a minimum of 6 years experience in aircraft engines or airframes. You should have extensive design experience, including plenty of board time, shop contact, structural design, stress analysis. You will be working directly with design engineers and layout draftsmen on design of light weight, complex structures.

In addition to the unusual career opportunities these positions provide, you will enjoy all the advantages of beautiful residential communities, situated amid lakes and mountains, yet less than an hour's easy drive from New York City. Further details may be obtained by writing a note or card to Curtiss Bacon at the address below.

RMI REACTION MOTORS INC.
50 FORD ROAD, DENVILLE, N.J.
POWER FOR PROGRESS

Radioplane to Become Division of Northrop

Radioplane Co. will become a division of Northrop Aircraft, Inc. later this year and the current subsidiary status will be dissolved. The name Radioplane will be retained.

Under divisional status, the vice president and general manager of Radioplane will have operational responsibility and authority. Whitley C. Collins, president of Northrop is also president of Radioplane.

Radioplane recently received a $6,631,765 contract for target drones and radio receiver selectors.

NAA Separates Missile Administration

North American Aviation, Inc., is separating manufacturing administration of its Missile Development Division from its Los Angeles Division in a series of steps to be completed by July 1.

The MDD organization will be headed by J. Y. Cunningham, general superintendent. Missile work at Los Angeles has consisted of tooling and sheet metal parts, machined parts, welding, assembly of large structural components on both SM-64 *Navaho* missile and booster.

R & D Costs at Temco Curtail Earnings

Temco Aircraft Corp. had sales of $27,226,605 for the first quarter of 1957 resulting in net earnings of $294,798. A year ago the figures were $19,621,602 and $644,847.

President Robert McCulloch said that the drop in earnings was because of costly research and development projects from which financial results have not yet been felt.

Among Temco development programs are the XKDT-1 rocket-powered missile target drone and the Navy *Corvus* missile.

Rocketdyne Engines Power Test Sleds

Liquid propellant rocket engines built by Rocketdyne division of North American Aviation, Inc., have accelerated 5,000-lb. test sleds to 900 mph in 4.2 sec.

The engines have been in use at Edwards and Holloman Air Force Bases for more than four years in connection with missile and aircraft development programs. They produce between 35,000 and 50,000 lbs. of thrust.

The Rocketdyne engine reaches 80% of full thrust in 1/10 sec. accel-

erating at 10 g's. One of the engines has been fired more than 120 times.

Rocketdyne describes the engines as nitrogen pressurized systems using propellant mixtures of alcohol and liquid oxygen. The propellants, pressurized at 3,000 psi, are introduced by high speed valves into the thrust chamber through an injector plate. Multiple holes in the plate, drilled at various angles, effectively mix fuel and oxidizer for the most efficient combustion combination. Mixture burns at about 4,700°F at full thrust.

The sled engine principle of operation is basically the same as larger liquid propulsion systems manufactured for long-range missile use.

Rocketdyne Sets Up Service Division

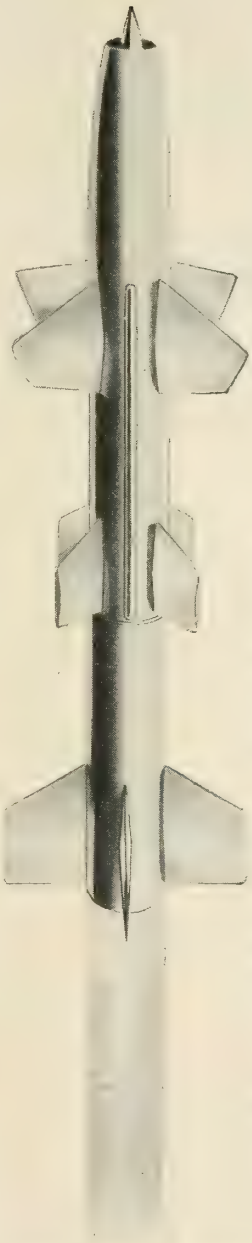
North American Aviation's Rocketdyne Division has set up a service division to speed up and simplify maintenance and supply for ballistic missiles.

Manager of the unit is J. A. Broadstone, former manager of Rocketdyne's propulsion field laboratory. Rocketdyne responsibility will include maintaining inventory of all parts through a warehouse system, operation of an overhaul and modification center, and the manufacture of spare and modified parts.

Army Seeks Money To Overhaul *Nikes*

Army has asked for funds to rebuild some 4,000 *Nike* missiles in fiscal 1958, according to House Appropriation Subcommittee testimony.

Corrosion and deterioration of parts from exposure and repeated testings were cited as reasons for the rebuilding. Some of the *Nikes*, Army revealed, have been in launchers for 20 months.



No costs have been mentioned.

Garrett Sales Up 33.5%

The Garrett Corp. reports a net profit of $3,563,651 from consolidated sales of $131,468,678 for the nine months ending March 31. Sales figures represent an increase of 33.5% over the same period last year. Current backlog is reported at $155 million, $50 million more than at same time in 1956.

Olin Mathieson Sales Down

Olin Mathieson Chemical Corp. reports first quarter sales in the U.S. and Canada of $135,479,249 and net income of $10,009,979. Year ago sales were $144,340,677, earnings were $10,080,099.

ENGINEERS GROW FASTER —GO FARTHER WITH

Bendix

Prime Contractor for TALOS GUIDED MISSILE

It just makes good sense—your opportunities are always bigger and better when you play in the big leagues.

Here at Bendix Guided Missiles our entire operation is definitely "big league". With Bendix, prime contractor for the important and successful Talos Missile, there is literally an open field for advancement for an ambitious engineer who can accept the responsibilities that go with opportunity.

The range of technical job opportunities is far wider than in companies where guided missile work is a secondary project. Everyone you will be associated with at Bendix Guided Missiles is first and foremost a missile engineer—many of the engineers are ranked with the outstanding authorities in the entire industry.

If you want to enjoy the advantages available in the rapidly growing guided missile industry, you can make no better start than by completing and returning to us the coupon for the booklet "Your Future in Guided Missiles".

Bendix Products Division—Missiles
412 M, Bendix Drive, South Bend, Indiana

Gentlemen: I would like more information concerning opportunities in guided missiles. Please send me the booklet "Your Future In Guided Missiles."

CITY_____ STATE_____

RCA... MISSILES... WHITE SANDS...

TRY TOPPING THAT COMBINATION FOR A FUTURE IN ELECTRONICS ENGINEERING!

Here's everything an RCA missile position at White Sands means to an engineer with prime ability. You will probe outer edges of missile technology, working on our nation's most complete guided missile weapon system. You will share with top engineers in the field RCA assignments in ground support systems, missile guidance and complex launching systems. You must, of course, have your EE, ME or Physics degree, several years' electronic design experience . . . and must be familiar with one of these fields:

System and sub-system analysis	**Internal instrumentation**
Reliability data control	**Equipment control**
Evaluation of new components	**Data analysis**

Projects will be related to sub-systems such as:

Precision radars	**Data processing equipment**
Digital devices	**Fire control**
Analog devices	**Data simulation**

Start at an excellent salary . . . A full program of liberal benefits gives your income added security. RCA's Tuition Refund Plan will provide for advanced studies. RCA pays relocation expenses.

Boeing Vibrator Mount Aids *Bomarc* Testing

A vibrator mount which eliminates unwanted outside vibrations is being used at the Pilotless Aircraft Division of Boeing Airplane Co. in the testing of instruments used in the *Bomarc*.

The Boeing-developed tool consists of a 5,000-lb. concrete triangle which is suspended on six oppositely-wound coil springs inside a steel frame.

The vibrator is suspended in a large cup inside the triangle. The depressed housing of the vibrator places it at a point which is both the center of suspension and center of gravity. As a result, when the vibrator is pivoted to any degree between horizontal and vertical, gravity will not create a conflicting force upon the direction of the vibration.

The equipment is called a "Seismic Mount for a Vibration Calibrator." It virtually eliminates unwanted vibrations except those near and below 1½ cycles per second.

Vibrations varying from 2 to 2,000 cycles per second and attaining a force of 20 g's can be generated.

Converter Translates Computer Data

A bilingual electronic computer that "speaks" in both analog and digital terms is making faster, more flexible and more accurate calculations in Convair's *Atlas* ICBM performance study.

Analog and digital computers, essential tools of aircraft and missile designing, do not "speak" the same language. Analog systems, for example, express quantity by measurable physical characteristics such as voltage, rotation and resistance. Digital systems express quantity in exact numbers.

Analog computers are fast, but lack accuracy and flexibility. Digital computers are highly accurate and flexible but often are not fast enough.

Convair-Astronautics and Epsco, Inc., have succeeded in mating the two computing systems on a large scale. A $200,000 computer-converter called Addaverter converts problem data from analog to digital and digital to analog, thereby uniting the best features and decreasing the disadvantages.

To bridge the equipment with the Addaverter requires 7,700 lbs. of electronic materials housed in cabinets eight ft. high, 15 ft. long and two ft. deep. The Addaverter contains 2,000

vacuum tubes and about 4,500 germanium diodes. Its display panel contains nearly 600 flashing lights. It uses 15,000 watts.

Terrier Missiles Get Radar System

U. S. Navy's *Terrier* missiles are guided by long-range radar capable of scanning airspace many miles beyond the horizon, according to Sperry Gyroscope Co. which makes radar system.

The SPQ-5 radar can select individual targets from close-flying groups and track them for missile guidance and interception.

Now installed on the missile cruiser Canberra, the radar antennas resemble giant searchlights. The USS Boston is also *Terrier*-equipped and three other ships are being fitted—the *Topeka, Providence* and *Springfield.*

Sperry Piedmont Co., a Sperry facility, is producing the radar at Charlotteville, Va.

Elgin Watch to Build R & D Plant Near LA

Micronics Division of Elgin National Watch Co. will construct a research and development plant in the Los Angeles area to handle expanding west coast operations.

The 20,000-sq. ft. building will be at Canoga Park and occupancy is expected by September 1. Micronics is engaged in the development of high-precision missile and aircraft parts.

Aerojet Workers Get 7 Cent Wage Hike

Aerojet-General Corp. hourly employes received a 7¢ per hour wage increase effective May 13 in accordance with a two-year agreement negotiated a year ago with the International Association of Machinists.

At the same time the company announced a 3% general increase for salaried employes, effective May 16. The company had about 6,500 hourly and 3,300 salaried employes.

Hoffman Sales Increasing

Hoffman Electronics Corp. realized a first quarter net profit of $512,802 on sales of $11,493,599, compared to net of $467,994 and sales of $12,155,-019 in same period last year. Company predicts 1957 sales and earnings 10% above 1956.

Missile Control Systems

Mechanical Engineers with 2-6 years experience in

Inertial Guidance Systems
Gyro Development
Product Design and Packaging
Servomechanisms

Ford Instrument Company's new Missile Development Division is expanding because of increased activity on guidance and control work for major ballistic missiles such as the Redstone and Jupiter.

Are you interested in the opportunities this could bring you — and the increased responsibilities? To those engineers who feel they can measure up to the high standards of our engineering staff and who wish to do research, development and design work in the expanding new field of missile engineering, write or phone Allen Schwab for an appointment or further information.

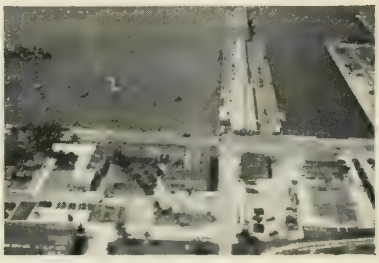
THIS IS Westinghouse BALTIMORE

An Engineer's Company Where Pioneering Progress Pays Off for Engineers Able to Meet the Challenge

At Westinghouse-Baltimore, Engineers are making history in the electronics field. In the seven operations that comprise the Baltimore Divisions, excellent opportunities are available for engineers interested in research, design, development and production work—on airborne, ground and shipboard electronic systems, Ordnance, X-Ray, Carrier Microwave, and Induction Heating equipment. Write today and find out where your engineering experience and talents can be best put to work on tomorrow's new dimensions.



AIR ARM offers exciting projects, including the Aero-13 Armament Control System and advanced concepts in Fixed Fire Control Systems, Bomber Defense Systems, Missiles Sub-Systems, and Surveillance Radar.

ELECTRONICS engineers revolutionized radar with the amazing Paraballoon. The Electronics Engineering Department is engaged in Communications, Missile Ground Control Engineering, Advanced Development, and Radar Engineering.

ELECTRONIC SERVICE DEPARTMENT Field Engineers service Westinghouse Air Arm and Electronics products around the world.

ORDNANCE DEPARTMENT . . . maintains a field site at Key West, Florida for testing underwater ordnance devices.

X-RAY DEPARTMENT specializes in creative engineering, as exemplified in the unique Cine-Fluorex Machine.

CARRIER MICROWAVE DEPARTMENT engineers designed and developed the small K-R All-Transistor Carrier Relaying set.

INDUSTRIAL ELECTRONICS DEPARTMENT . . . specialists in Induction Heating equipment for the metal working industry.

FOR MORE INFORMATION ON THIS "ENGINEER'S COMPANY" SEND FOR THE ENGINEER'S CAREER BOOK—"NEW DIMENSIONS".

Write to Dr. J. A. Medwin, Dept. 679, Westinghouse Electric Corporation, P. O. Box 746, Baltimore 3, Md. Please indicate your degree, year of graduation and field of interest. For a confidential interview, include a resume of your education and experience.

Westinghouse - BALTIMORE

An Engineer's Company

Advanced Electronics Systems, Ordnance, X-Ray, Carrier Microwave, and Induction Heating Equipment for Military, Industrial, and Commercial Purposes.

SINCE 1886

German Rocket Growth Slow But Sure

There is little rocket industry as yet in Germany but from numerous points there are indications that development is underway. One such organization, Bölkow Luftfahrtenwicklungen KG (Bölkow Aero Developments) have a Sam or anti-tank rocket in advanced stages of development. Bölkow, 42, of Stuttgart, is well acquainted with U.S. developments. Another organization becoming active is the Raketenfertigungs-GmbH (Rocket Assembling, Inc.) of Giessen.

From Munich it is learned that Mr. Richard Stangler, head of German Association of Aircraft Standard Parts Industry, Frankfurt, has formed a Verband der Raketenindustrie (Association of the Rocket Industry).

Ingots Produced From Compacted Sponge

Oregon Metallurgical Corp. is producing titanium and zirconium ingots and billets from compacted sponge, utilizing the technique of consumable electrode, arc melting under vacuum or inert gas in a water-cooled copper crucible.

Ingots are available as pure titanium, zirconium, or alloyed with chromium, manganese, tantalum, columbium, platinum or other alloy combinations.

North American Gets Options on Nevada Site

North American Aviation, Inc., has obtained options to purchase some 12,600 acres in Washoe County, Nev. The property is located 10 miles northeast of Reno.

The location is being considered among others for future development of manufacturing and test facilities, possibly in electromechanical and rocket fields, according to J. S. Smithson, vice president—administration.

Marquardt Sales Up

Marquardt Aircraft Co. reports sales of a 16-week period ending April 27 were $11 million, up 110% over the comparable period a year ago. Net profit for the period was $235,000.

Stockholders have approved an increase in company's stock from 300,000 to 1 million shares.

Aerojet gets JATO Order

Aerojet-General Corp. has received a $3.5 million contract from Navy Bureau of Ordnance for manufacture of JATO units and spare igniters. The solid-propellant perchlorate oxidizer units will be made at Sacramento.

Ryan Gets $4 Million For More *Firebees*

Ryan Aeronautical Co. has received a contract in excess of $4 million for a quantity of KDA-1 *Firebee* jet target drones for the Navy. The new order closely follows other *Firebee* contracts totaling $15,500,000 from the Air Force and Navy.

Orders for the drone missiles will require expanded production schedules well into 1958, according to president T. Claude Ryan.

Republic Quarter Sales Top $76 Million

Republic Aviation Corp. consolidated sales for the first quarter amounted to $76,645,222 and net income stood at $1,776,738 or $1.21 a share. This compares with figures of $81,798,731 sales and $2,129,663 or $1.45 a share earnings in the first quarter of 1956.

Republic's backlog March 31 was $177 million and contracts being negotiated at that time were valued at an additional $371 million.

ARDC Opens Office In San Francisco Area

Air Research and Development Command has opened a new development field office in the San Francisco Bay area to provide a close link with private research institutions and industries in the region.

The office is temporarily located at Moffett Field but the permanent location will be in or near Palo Alto. In charge is Capt. Otis R. Hill, formerly of ARDC headquarters, Baltimore.

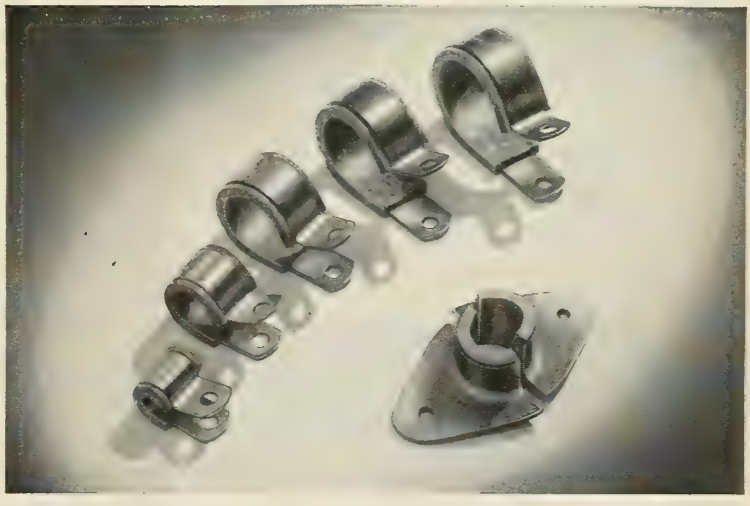
Siegler Gets Contracts For *Atlas, Titan* Gear

The Siegler Corp.'s Hallamore Electronics Division has received a contract of more than $9 million for engineering and production of a high-priority guided missile program.

The contract reportedly is for electronic test and check-out equipment for the Martin *Titan*. Earlier Siegler received a $4 million contract for similar test and check-out gear for Convair's *Atlas*.

AN FITTINGS

Stainless, Aluminum, Brass, Steel. All sizes—immediate delivery from world's largest shelf stock. Buy direct from manufacturer. Lower prices—quicker service. Send for free wall charts showing complete line of AN Fittings.



COLLINS ENGINEERING CO.
9050 Washington Blvd., Culver City, Calif.

for precision short-run machine operations on your small, intricate prototypes involving sub-assemblies and electromechanical components. Our *completely equipped* plants are presently producing for the leading Military, Electronic and Aviation firms throughout the entire western region. Let us know your requirements—send prints for bids.

20 page brochure on our facilities sent on request—write TODAY!

GRIMLEY ENGINEERING CORP.
177 W. Magnolia Boulevard, Burbank, California
Circle No. 72 on Subscriber Service Card.

Anyone can make a metal clamp, but one lined like this takes a bit of doing

Take asbestos, reinforce with wire mesh, impregnate with DuPont Teflon and mold to shape . . . a new conception in high temperature clamps, one
—that will take temperatures from —300 to +500 F
—that will never harden nor melt
—that will stand corrosive fumes, oils, hydraulic fluids, solvents, fuels
—that will absorb constant vibration and stay on the job
and do its work. Write for samples and quotations.

The Joclin manufacturing company
22 Lufbery Avenue
Wallingford, Connecticut

Circle No. 73 on Subscriber Service Card.

Speakers at Southern Research Institute's recent Space Flight Symposium included: Erik Bergaust, Exec. Ed., m/r; Dr. Ernst Stuhlinger, ABMA; Dan A. Kimball, pres., Aerojet-General; F. L. LaQue, v.p., International Nickel Co.; Gen. D. C. Ogle, AF Surgeon General; Dr. J. P. Hagen, Project Vanguard Chief; Dr. C. C. Furnas, former Assistant Defense Secretary.

KERR

James R. Kerr has been appointed president of Lycoming Div., Avco Mfg. Corp. His current assignment is head of Avco's Office of Defense Planning.

Joseph F. Caslin has joined the Associated Missile Products Corporation as staff assistant to the gen. mgr. Prior to this appointment he was head of the guided missile ground support equipment div. of the Turbo Div., American Machine and Foundry Co.

Dr. J. Victor Hughes has joined the scientific research staff of Republic Aviation Corp. as an associate scientist. He was director of the general physics laboratory of Continental Can Co.

Kenneth B. Boothe has been named director of sales for Kahn Research Laboratories.

Robert N. Himmel and **R. Kenneth Davis** will staff the new Semiconductor-Components division marketing office of Texas Instruments at Camden, N.J.

Gene Lowe has been appointed vice president—manufacturing at the Benson-Lehner Corp.

Leroy W. Collins, formerly with International Latex Corp., has been appointed personnel mgr. of the Mechatrol Div. of Servomechanisms, Inc.

Harold W. Gear of Magnavox Corp. has joined the Chemistry Div. of the Atlantic Research Corp., Alexandria, Va., as processing supervisor of solid propellant rocket fuel charges. **Howard H. Niederman** has joined the Western Div. of Atlantic Research as consultant in solid propellant rocketry and chemical engineering.

Samuel M. Kinney, Jr., has been elected secretary of Daystrom, Inc., Roy Sandquist has been elected treasurer, and Robert R. Whelan, asst. secretary.

Col. John P. Gibbons of the Air Materiel Command will be the Air Force plant representative for The Martin Co.'s Guided Missiles Division at Denver.

J. Russell Clark has been promoted from asst. chief engineer—aircraft projects to chief engineer—aircraft, and Samuel O. Perry from asst. chief engineer—missile projects to chief engineer—missiles at Chance Vought Aircraft, Inc.

TERRY

Philip D. Terry, formerly an aircraft field engineer with the Los Angeles Valve and Pump Co., has been named field engineer in charge of missile equipment and systems for Wm. R. Whittaker Co., Ltd.

Oscar T. Simpson has been named gen. mgr. of the new Western Development Laboratories of Philco Corp.'s Government and Industrial Div., at Redwood City, Calif. **Dr. Walter LaBerge** has been named mgr. of systems engineering. **Donold H. Clague** is business mgr.

MERRILL

Howard W. Merrill, director of operations at the Martin Baltimore Div., has been named a vice president of the company and gen. mgr. at Baltimore, succeeding **William B. Bergen** who remains executive vice president.

Robert L. Trent has joined Texas Instruments Inc. to direct a new engineering branch for applications and test equipment in the Semiconductor-Components Div. **R. J. Hanschen** has been appointed Mid-America region sales mgr. for the division.

Reaction Motors' Robertson Younquist, Tiokol's H. W. Ritchey and Douglas' R. B. Canright talk it over at recent French Lick, Ind., meeting of the Commercial Chemical Development Assn.

missile literature

ELECTRONIC EQUIPMENT RACKS. Illustrated 4-page brochure describes aluminum racks designed to accommodate standard RETMA panels of mobile electronic equipment. Craig Systems, Inc.
Circle No. 100 on Subscriber Service Card.

SHAFT ANGLE CONVERTERS. Instrument which converts rotary motion into coded system of numbers described in 4-page brochure. Specifications, drawings, other data presented. Instrument Development Laboratories, Inc.
Circle No. 101 on Subscriber Service Card.

TESTING FACILITIES. Environmental, metallurgical, chemical and quality control testing facilities outlined in 24-page brochure. Burgoyne Testing Laboratories, Inc.
Circle No. 102 on Subscriber Service Card.

METAL CASES. Stock sizes and shapes of instrument cases for special requirements of humidity, pressure, corrosion and MIL specs available to designers given in 62-page catalog. Zero Manufacturing Co.
Circle No. 103 on Subscriber Service Card.

BREATHING UNIT. Data sheet describes unit to protect workers during missile and rocket fuel handling operations. Scott Aviation Corp.
Circle No. 104 on Subscriber Service Card.

MISSILE FACILITIES. Capabilities and facilities of Rocket and Guided Missile Division to handle applied research and engineering, mass production of missiles and components described in 20-page brochure. National Electric Products Corp.
Circle No. 105 on Subscriber Service Card.

STAINLESS STEEL DATA. Handy 32-page booklet has 20 tables including detailed data on stainless steel finder, corrosion resistance of various stainless steels, fabrication properties, weight tables. Allegheny Ludlum Steel Corp.
Circle No. 106 on Subscriber Service Card.

REINFORCED PLASTICS. Complete ranges of fiber glass fabrics and fibers, polyester and epoxy resins and catalysts covered in 14-page book. Two pages of property tables of polyester resins and fiber glass cloths included. Cadillac Plastic & Chemical Co.
Circle No. 107 on Subscriber Service Card.

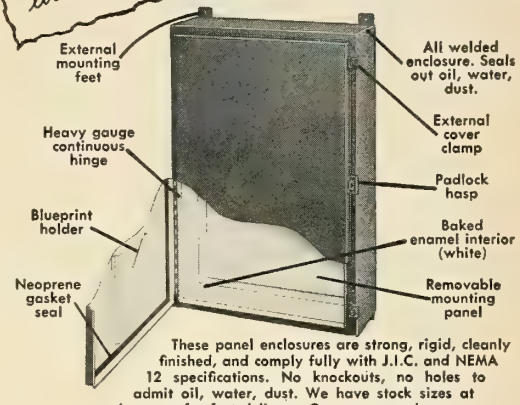
SCREW-LOCKS. Comprehensive 8-page specification bulletin contains tables with thread sizes, insert numbers and sizes, complete information on drilling, tapping, gaging and installation. Heli-Coil Corp.
Circle No. 108 on Subscriber Service Card.

BATTERY CONNECTORS. Information on battery connectors, power connectors and heavy duty connectors for many applications contained in 32-page catalog. Cannon Electric Co.
Circle No. 109 on Subscriber Service Card.

HYDROFORMING. Complete service for forming prototypes and pre-production parts in missile and other industries outlined in 4-page pamphlet. C. B. Kaupp & Sons.
Circle No. 114 on Subscriber Service Card.

TURBINE FLOW METER. Device for precise measurement of liquid flow is detailed in 8-page catalog, giving missile and aircraft applications. Fischer & Porter Co.
Circle No. 115 on Subscriber Service Card.

TIME DELAY RELAYS, REPEAT CYCLE TIMERS. Two 2-page bulletins contains details on construction of three basic time delay relays in new extruded hermetic housings, and three basic miniature repeat cycle timers. A. W. Haydon Co.
Circle No. 116 on Subscriber Service Card.



COUPLINGS, MISSILE APPLICATIONS. Complete line of hydraulic couplings, military test results, sizes, advantages covered in 4-page brochure. Second 4-page booklet lists missile uses, describes types used in launching, fueling, electrical checkout, rigid fuel lines, monofuel exhaust line. E. B. Wiggins Oil Tool Co., Inc.
Circle No. 117 on Subscriber Service Card.

AUXILIARY POWER, COMPRESSOR, PNEUMATIC SYSTEMS. Two 12-page brochures outline operating and weight characteristics of compressors, pneumatic systems, auxiliary power systems for missiles or manned aircraft. Walter Kidde & Co., Inc.
Circle No. 118 on Subscriber Service Card.

PRODUCTION KNOW-HOW

The organization and facilities of the newly streamlined Rheem Aircraft Division are geared to produce aircraft and missile airframe assemblies in high production quantity. New and modern operational concepts are being constantly applied to the basic talents and facilities available at Rheem Aircraft Division to assure the aircraft, propulsion, and ordnance industries of an on-schedule, high quality, low cost producer. Your letter of inquiry will receive prompt attention from our Marketing Department. *Rheem has manufactured more than 10,000 major aircraft assemblies since 1951.*

Rheem

The research and development activity at Rheem is engaged in the conception, evaluation, and design of drone and small missile systems and explosive and ordnance products.

Engineers: join the 600 Rheem engineers in challenging technical work. Send resume to Personnel Manager, Aircraft Division, Rheem Mfg. Co. All inquiries held strictly confidential.

guiding hand for tomorrow's power

Skilled hands coupled with keen minds made today's rocket powerplants a reality. Minds that formulate new theories in powerplant design . . . and hands that prove these theories by careful experiment, test and application.

Guided by such hands and minds, RMI has led the way for over fifteen years—designing and producing record-breaking powerplants for such supersonic vehicles as the X-1A, Skyrocket and the Viking missile. Today and in the future, RMI engineers and scientists will continue to blaze the trail toward advanced propulsion systems for manned and guided flight.

Engineers, Scientists—Perhaps you, too, can work with America's *first* rocket family. You'll find the problems challenging, the rewards great.

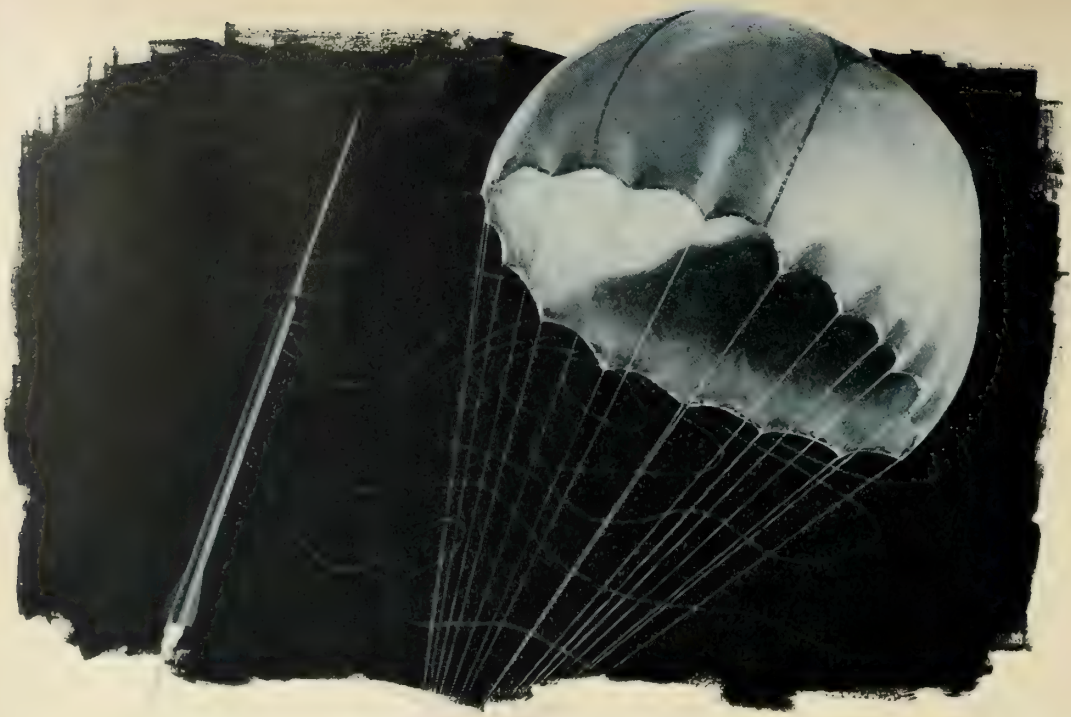
GOING UP?

When it's time for a missile to go up—into the firing position—SUN Hydraulic Power Units will raise it safely and smoothly—providing a source of hydraulic power prior to the moment the missile systems become self-sustaining.

SUN Hydraulic Power Units are built to the exacting requirements demanded of auxiliary and ground support equipment for ICBM, IRBM and other missile projects. When *performance without failure*—even under the most gruelling conditions of abnormal temperature, humidity, dust, vibration or shock—is a must, depend upon SUN Equipment for reliable, trouble-free support.



SUN ELECTRIC CORPORATION designs and builds electric, electronic, hydraulic test and power equipment for the automotive and aircraft industries and for the field of astronautics.

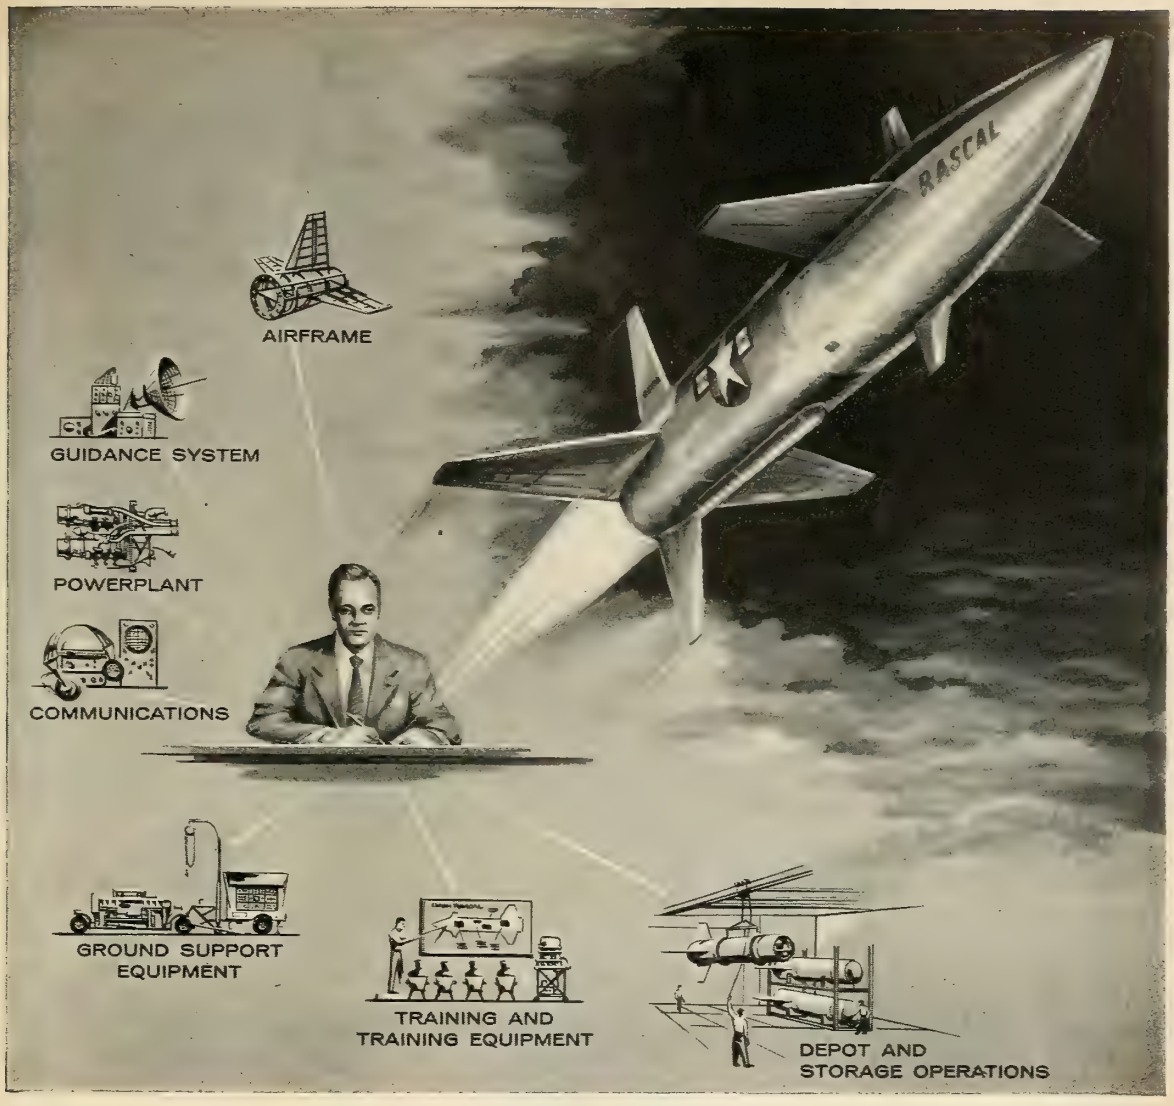
WHAT'S THE WEATHER 30 MILES UP?

CDC WASP REPORTS BACK IN 60 SECONDS

THE WASP IS A SINGLE STAGE SOLID PROPELLANT ROCKET
LENGTH: 103", DIAMETER: 3", WEIGHT: 22.5 LB.

That's a radar reflective chute just ejected from a CDC rocket launched only 60 seconds ago. Far below, a Navy research team is getting instantaneous answers to important weather questions—filling gaps in man's knowledge about wind profiles between *50,000* and *200,000* feet.

This missile system is currently performing useful research tasks for NOL, ONR, Redstone and the Signal Corps. It also is being employed in the IGY program. Redesigned from the LOKI missile developed by Cal Tech Jet Propulsion Lab for Army Ordnance, it is an outstanding example of CDC creativity. CDC offers full services in design, development, instrumentation, fabrication, field testing and data evaluation. How can CDC serve *you?*



Write for detailed information on CDC capabilities in rocket and electronic systems for scientific and military applications.

Weapon Systems Management

.....IS OUR BUSINESS

The air-to-surface GAM-63 "Rascal" of the USAF has already clearly demonstrated the capabilities of Bell Aircraft Corporation's ***Guided Missiles Division*** for the complete and highly efficient management of any weapon systems program.

This large and diversified team of specialists has the skills and experience necessary to follow a system through from the idea stage until it is operational. Each step—each phase is closely coordinated with time an ever essential consideration. Airframe, power plant and avionics are interrelated. Test and training devices, personnel training, ground support equipment and auxiliary systems follow in their proper sequence. The system comes into being under unified, centralized management—with dispatch and efficiency not possible in assembling component units which have been produced under a divided responsibility.

Some 100,000 man years of experience in this field have been logged by the men in the ***Guided Missiles Division.*** Their past is history worthy—their future important in our national defense.

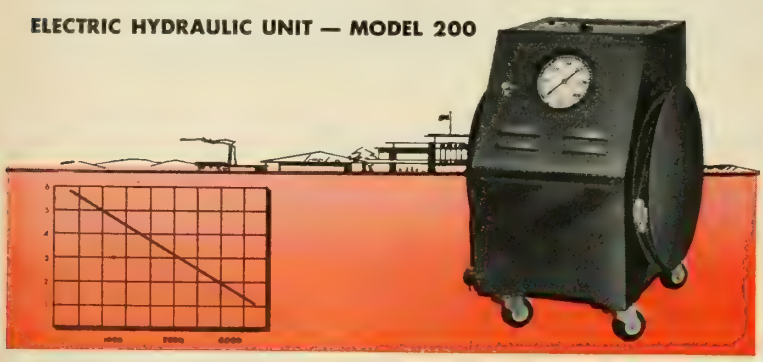
COMPACT AND EFFICIENT

HYDRAULIC POWER UNITS

FOR APPLICATIONS TO 3000 PSI

The operating characteristics are interesting and one or both of these units may be able to do a specific job for you. Each unit is completely proven and has been skillfully designed for varied utilization, low cost, simplicity of operation and maintenance, and ease of transportation.



AIR HYDRAULIC UNIT — MODEL 100

This unit is explosion proof and features a demand system with constant pressure to 3000 psi. Pressure is accurately adjustable to 25 psi, the system is filtered and is powered by a piston-type, air-hydraulic booster pump incorporating an automatically operated air selector valve. All parts are commercially available.

SPECIFICATIONS:
Dimensions—19½" x 11¾" x 14" high.
Weight—75 pounds.
¼" pressure and return hoses, ⅜" air supply hose and 1 gallon reservoir.

ELECTRIC HYDRAULIC UNIT — MODEL 200

This 110V ac or dc unit features a demand system with constant pressure to 3000 psi. Pressure is accurately adjustable to 25 psi, the system is filtered and is powered by a high-speed, high efficiency gear pump. All parts are commercially available.

SPECIFICATIONS:
Dimensions—16¼" x 14¼" x 23" high.
Weight—85 pounds.
¼" pressure and return hoses,
110V ac or dc power, 1 gallon reservoir
and ½ hp, 115V motor.

Both of these units may be modified to conform to customer specifications.

design with austenal in mind

New **VACUUM MELTING** *techniques being developed by* **MICROCAST** *give promise of higher performance parts for the future*

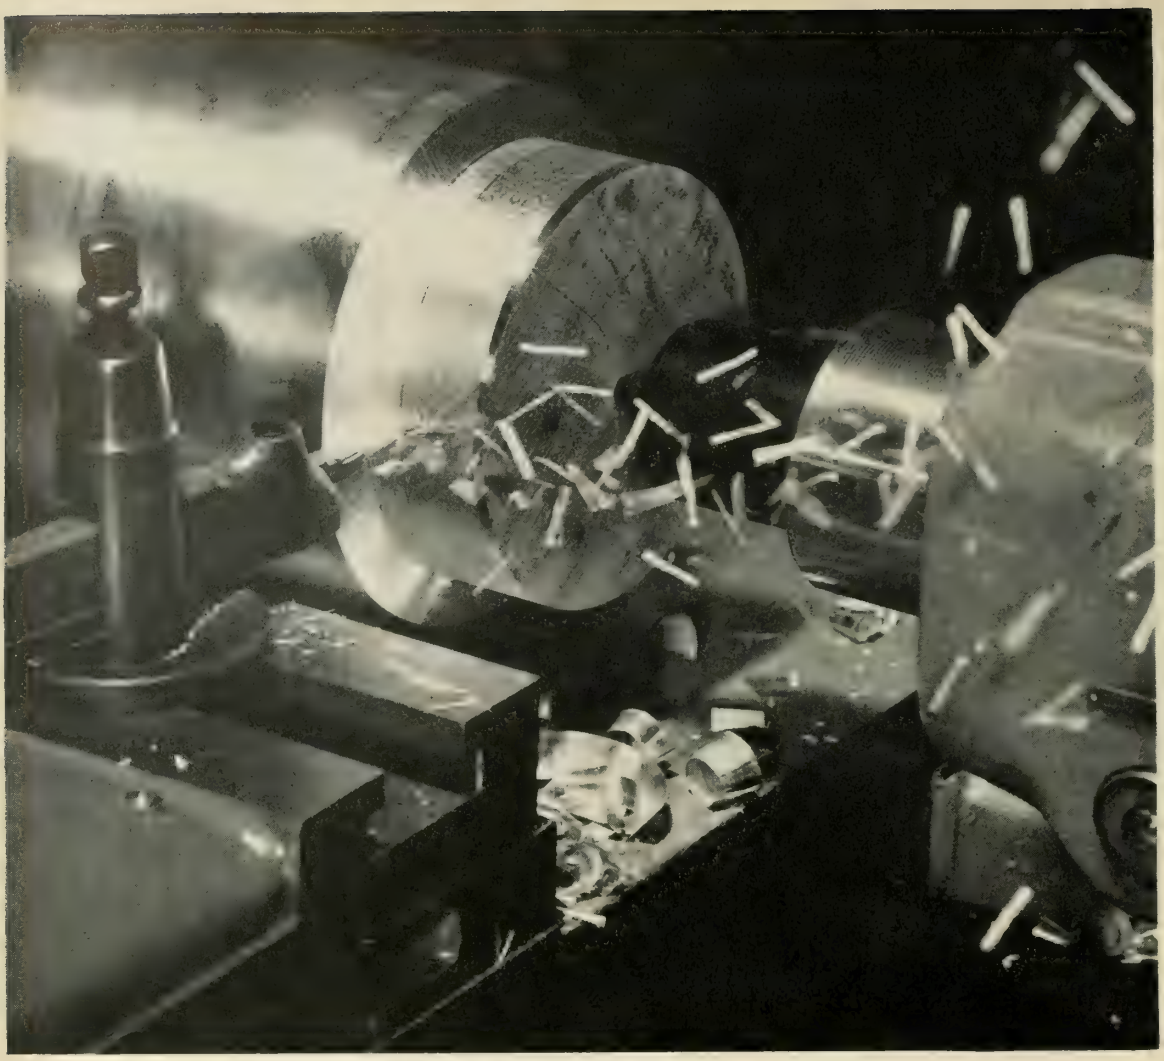
Austenal vacuum melting and casting techniques being currently developed may have a big place in your future designs.

Vacuum melting promises greatly improved investment castings and a wider range of cast parts, because it makes available alloys with outstanding high temperature properties. By removing harmful gases and holding down objectionable oxide inclusions, vacuum melting results in parts that are more ductile, stronger and tougher than before. Vacuum melting makes possible the use of alloys that were formerly uncastable.

For instance, these new Austenal techniques are already being studied for aircraft manufacturers on a development basis. Vacuum melting has helped furnish extremely high quality vanes and blades for future jet engines.

Discuss this new Austenal development with your Austenal representative. Vacuum melting may be the way for you to obtain higher performance in designing parts for tough jobs of the future.

---*It's* **NEW** *from Austenal*



Vacuum casting of turbine buckets such as this has been accomplished and the application of this method is being planned for other jet engine components.

Speed! Of all structural metals, Magnesium costs less to machine

In the picture above, a lathe is making a roughing cut of 0.800″ in an eight inch magnesium billet. The feed is 0.030 inches per revolution at a speed of 630 feet per minute. In finishing operations, cuts of 0.500″ can be made with a feed of 0.003 ipr and a speed of 5,000 fpm.

That's real speed and efficiency—the kind you can always expect when you machine magnesium. This remarkable metal can be milled, drilled, sawed, reamed, bored, planed, tapped and threaded faster than any other structural metal!

Faster machining means easier machining and lower cost machining. It means more production per hour and per dollar, and longer tool life.

The following table shows how well magnesium compares to the others:

METAL	RELATIVE MACHINABILITY
magnesium	**1.0**
cast aluminum	**1.8**
brass	**2.3**
cast iron	**3.5**
rolled aluminum	**5.0**
mild steel	**6.5**

Let us give you more information about the machinability of magnesium. Contact the nearest Dow sales office or write to THE DOW CHEMICAL COMPANY, Magnesium Department, Midland, Michigan, Dept. MA 1404G.

YOU CAN DEPEND ON **DOW**

On target

for guidance control drives with "impossible" accuracy!

Manufacturers of electronic equipment requiring accuracies hitherto impossible are pointing to Western Gear for the gears and units to drive and control their incredibly accurate equipment. Until now, mechanical accuracies have not been able to keep pace with the 100% reliability requirements of this equipment. But Western Gear research, design and manufacturing engineers have combined their talents to develop new methods and techniques for the production of intricate gear assemblies, gear control systems and even complete installations of a wide range of electronic equipment for ballistics and guidance. In this production, tolerances to 1/10,000 of an inch are commonplace, and we have equipment capable of working to 1 *millionth* of an inch, and repeating itself. If you have been told your guidance drive tolerance requirements are "impossible," call your Western Gear man. Write to Box 182, Lynwood, California for his name and address.

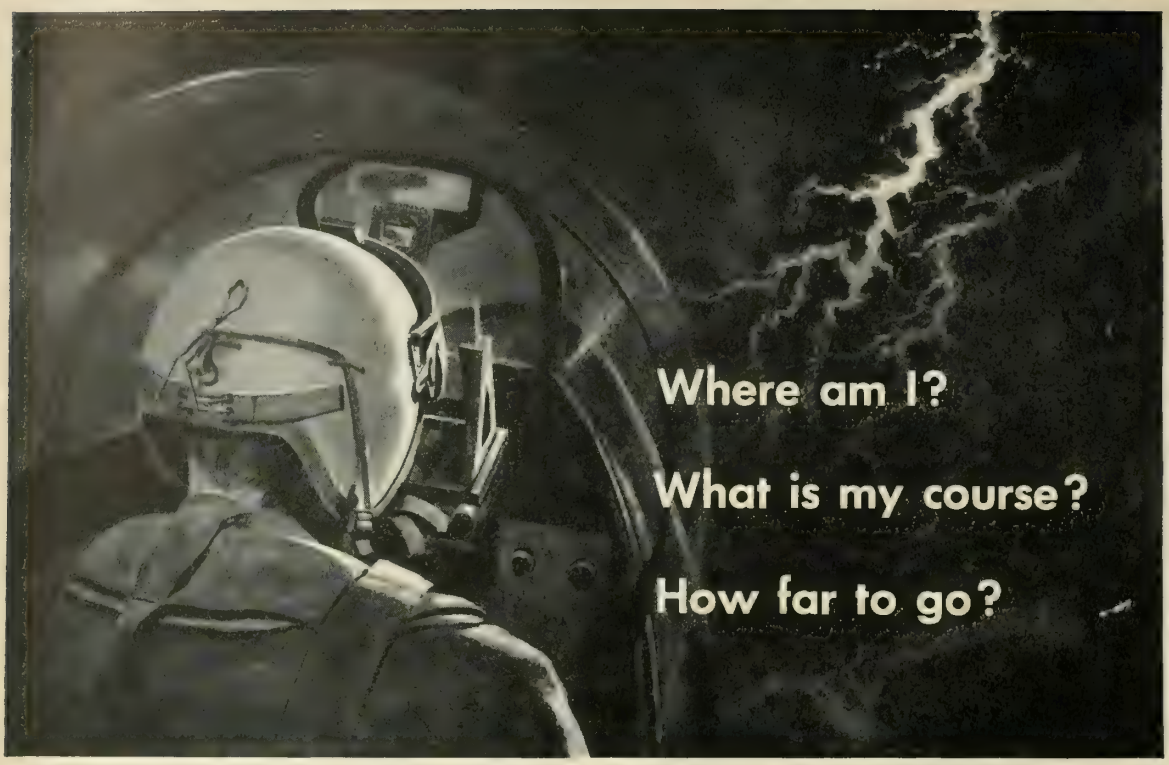
Science and Common Sense

Radioactivity was discovered by Becquerel and explained by Lord Rutherford before 1900. In 1905, Albert Einstein postulated the equivalence of mass and energy according to the relationship $e=mc^2$. In 1945 a group of scientists crouched in Alamagordo's damp predawn to watch the world's first man-made nuclear blast sear the blackness. Nearly half a century elapsed from basic concept to weapon, although the same Albert Einstein advised President Roosevelt of the feasibility of an atomic bomb.

Today we would like the gap between idea and hardware be reckoned in months. The pace of development accelerates. To be sure, the scientist doesn't pull the trigger, or push the button, but he peers over the shoulder of the man who does.

We believe that the world is secure from nuclear self-annihilation only so long as the West maintains a weapons superiority that is obvious to the enemy. In general, this superiority is equidependent on: The discovery of new and better concepts; industry's ability to engineer and produce the hardware based on those concepts; and finally on men in authority recognizing the "next step" when they see it.

The need for people with a high degree of technical training is evident. Slowly, however, the problem of numbers is being solved. Missiles, rockets and space flight have fired the fancy of young America. More and more students in high school will tell you: "I want to be a missile engineer." Or, "I want to be aboard the first flight to the moon."



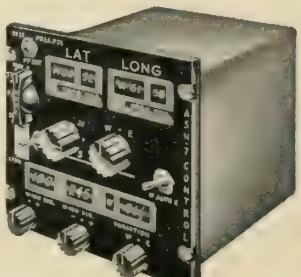
This is good. And for this purpose there is a primary need to lay more emphasis on the physical sciences as early as possible, especially in the upper high school grades. Fortunately this need is more and more recognized by educators and parent associations.

Also, the higher education at universities and colleges dealing with training of scientists and engineers must be broadened to avoid too narrow specialization. The modern history of aviation, especially the development of missiles and rockets, clearly shows that the engineer working in these fields needs education in more and more branches of the physical sciences. Aerodynamics became Aero-thermodynamics, then Aero-thermochemistry; for problems of guidance and command the aeronautical engineer must also be familiar with the broad field of electronics.

Essential is a constant awareness on the part of young people starting out that the world is complex and broadening—that all things in it are related.

This relates to a vital quality without which all the scientific ability imaginable would be to little avail. Instilling technological intuition—a working judgment of the physical sciences—into the business executive is tough enough. Even more difficult is the task of providing a broad base of *common sense* and evaluation for scientist and engineer whose whole educational and professional drive is high-lighted by specialization.

THEODORE VON KÁRMÁN.



NEW *PROVEN* COURSE AND DISTANCE COMPUTING SYSTEM SOLVES YOUR NAVIGATION PROBLEM—*FICo's ASN-7*

The flight-tested ASN-7 answers every navigational question the pilot can ask. Self-contained, automatic, this dead reckoning system is revolutionizing aerial navigation. In operation, the pilot sets in the latitude and longitude of his take-off point and of his destination, and the system guides him in—regardless of how his course changes, regardless of distance, and without air-ground or ground-air communication. Alternate destinations can be inserted and stored.

This FICo system can be installed in any aircraft—from jet fighters to tankers, bombers, transports and airliners. And it is in production now! It is smaller in size and lighter in weight than any comparable navigation system now in existence, and offers *extreme* accuracy. The ASN-7 features automatic variation and can be supplied with polar capabilities, automatic fix correction, and automatic drift and ground speed. For additional information, write to Airborne Equipment Department, Ford Instrument Co., on your letterhead.

FLIGHT INDICATOR of this system displays ground track, required course, heading error, and distance to the destination.

COMPUTER CONTROL feeds wind, variation, and destination data into the system. It displays present position, wind speed and direction, variation, and destination coordinates.

KEEPING INSTRUMENTATION A STEP AHEAD OF SPEED

AVIONICS IN ACTION AT BURROUGHS: FROM RESEARCH AND DEVELOPMENT TO PRECISION MASS PRODUCTION

Today's dramatic new developments in aircraft performance demand equally dramatic new developments in flight *instrumentation*. And Burroughs is assuming ever greater responsibilities in this field through its work in the brand-new science of *avionics*.

Examples? Past experience in mass production of such instruments as altimeters, accelerometers and gyros. Plus, of course, extensive research and development in totally new concepts of flight instrumentation. And in all these enterprises, *reliability* consistently keynotes our performance.

We have, too, the capabilities and facilities for further research and development in this fast-moving field. And in all areas of our proved responsibility and competence—not only instrumentation but control systems, electronic computation, communications, data processing and others—we stand ready to see defense contracts *all the way* through. Yes, from preliminary research to installation and field service.

Write, call or wire Burroughs Corporation, Defense Contracts Organization, Detroit 32, Michigan. Or Burroughs Defense District Offices: Paoli, Pa. • Dayton, Ohio, 3898 Linden Ave. • Encino, Calif., 17071 Ventura Blvd. • Washington, D.C., 1739 "H" St. N.W.

VICKERS®

Miniaturized

PISTON TYPE HYDRAULIC PUMPS

3000 psi . . . CONSTANT DISPLACEMENT

These new miniaturized hydraulic pumps were developed by Vickers for limited life applications such as missile and ram air turbine driven hydraulic systems . . . also for motorpump assemblies supplying emergency power on aircraft.

A distinctive feature is adaptability to manifolding and special mounting. This permits integration with the balance of a "packaged" hydraulic system to provide hydraulic power in the most compact and lightweight form yet devised. Some sizes are capable of delivering more than five horsepower per pound of weight.

Available in four size series, this miniaturized pump has the same basic characteristics as the standard Vickers piston type pump which has been establishing outstanding performance records on aircraft since 1940. Ask nearest Vickers Aircraft Application Engineer for further information.

Information manual about APL and its programs now available

The Applied Physics Laboratory (APL) of The Johns Hopkins University is unique in that we are neither an industrial nor an academic organization, but rather a composite, having drawn freely from the methodologies of each.

For thirteen years APL has pioneered in guided missiles. Today we are engaged in a broad program of R & D for the Navy; in addition, we are responsible for technical direction of industrial and academic contractors in developing the Terrier, Talos and other major weapons and weapons systems. Our staff members enjoy not only the stimulus of association with their immediate colleagues at APL, but also with those in other organizations of considerable stature.

NEW 30-PAGE PUBLICATION

A few positions for senior engineers and scientists are now open. Information on our accomplishments and goals is available in a new 30-page publication, just off the press.

In it staff leaders representing each of the various disciplines and fields outline the nature of their programs. Information on our new laboratory in Howard County, Md. (equidistant between Baltimore and Washington) is also included, together with facts on the outstanding communities in which our staff members live.

Quantity is somewhat limited. May we suggest you send now to: Professional Staff Appointments,

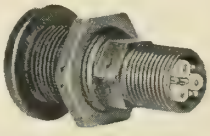
CEC's NEW LIGHTWEIGHT MINIATURE CONNECTOR FOR HIGH-ALTITUDE, HIGH-TEMPERATURE OPERATION



Consolidated's new series of miniature electrical connectors open new horizons for design engineers. Designed especially for the electronics, avionic, and instrumentation industries, these extremely reliable, multi-contact connectors meet or exceed MIL-E-5272A specifications. Recommended for all applications that require high-temperature characteristics, high breakdown voltage between pins and ground, low noise, and positive sealing against moisture and pressure leakage.

The unique cold-flow properties of the Teflon* inserts under compression provide a positive dielectric and mechanical seal against leakage and eliminate air voids between individual contacts and between contacts and ground. With CEC Connectors, no supplementary pressure-tight sealing is ever needed for missile applications.

**DuPont registered trademark. See drawing for exclusive CEC design features.*

cec's new miniature connector

with the biggest story

SUPERIOR ELECTRICAL CHARACTERISTICS

Now, you can achieve positive sealing against moisture, corrosion, explosive vapors, and pressure leakage without the inconvenience and expense of potting. Interchangeably male or female, CEC Connectors are available with 1, 3, 7, or 19 contacts in three differently shaped receptacle housings for cable-to-cable, cable-to-equipment, and bulkhead feed-through. A standard plug connector mates with all three receptacles. Compare these specifications—a small investment in some evaluation units now may save you time and expense in the future.

SPECIFICATIONS

Max. Operating Voltage
1. Sea Level.....1800-v, a-c
2. 70,000 feet.....800-v, a-c

Vibration.....No resonances to 2000 cps
Shock.....>200 g's
Temperature.....–67° to + 400°F
Contact Voltage Drop...<25 mv at 5 amps
Insulation Resistance.....$>10^6$ megohms
Humidity.....160°F, 14 days, 95% RH
Corrosion.....Salt spray per QQ-M-151a

Sidewinder Scores Again!—with Honeywell fuzing

NO ONE sophisticated in the ways of missiles would ever point out any single element calculated to assure a hit. There are too many important considerations.

But fuzing would have to be high on any list of vital factors.

And on Sidewinder, Honeywell is a supplier of fuzing that is completely and extremely reliable.

Sidewinder, one of the Navy's deadliest weapons, developed by the Naval Ordnance Test Station, China Lake, California, can home in with great accuracy from beyond the reach of enemy defense.

This simple, light air-to-air missile attacks at supersonic speed. And it's small enough to be carried in quantity by single seated interceptors.

Economical quantity production of fuzing for such a missile is possible with facilities like those at Honeywell Ordnance where all of the necessary equipment and manpower are available under one roof.

And experts in our ordnance division can draw upon a pool of over 30,000 skilled men and women in research, engineering, design and development, production and field service. Standing behind them is over seventy years of engineering and production know-how.

If you require development work in the areas of missile equipment, fuzing, fire control, underwater ordnance or special products, Honeywell Ordnance Division would welcome your inquiry. Phone, wire or write to Honeywell Ordnance Division, Dept. MI-7-195, Minneapolis 8, Minnesota.

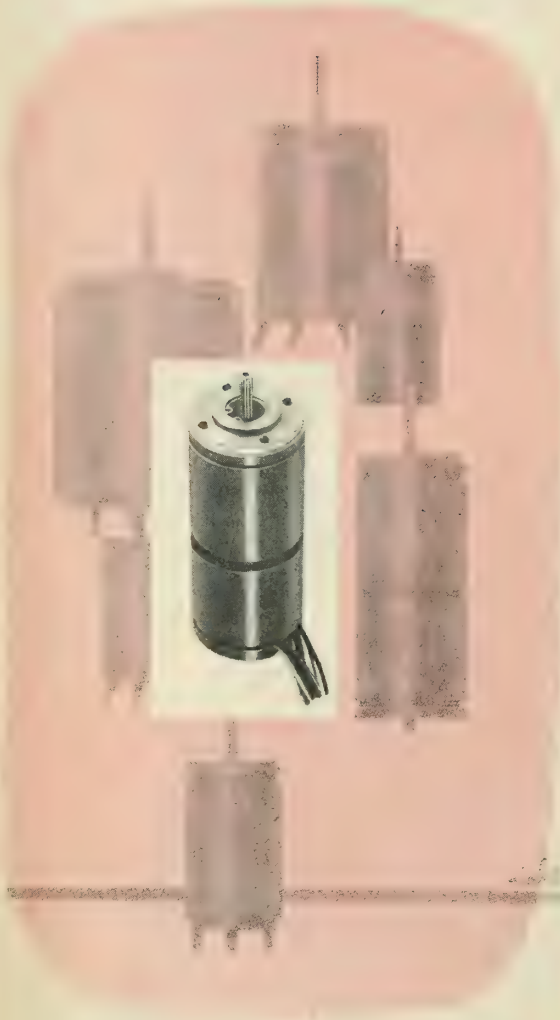
EDISON MINIATURE -- HI-TEMP



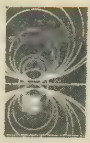
servo systems and components

The Edison Instrument Division is now offering design engineers an extensive line of miniature and subminiature Hi-Temp Servos and Servo Components . . . in addition to a complete facility for custom designed units and servo sub-systems.

Edison s Size 11 Motor Damping Generator for example, was built to such precise tolerances that a leading systems manufacturer was able to make this particular unit do double duty as a tachometer generator. This miniature unit's fast response and large output signal makes it ideal for applications where weight, size and high performance are prime requisites.

Precision production and rigid quality control inspection have made these "customized" components possible. In addition to these special units, Edison also manufactures an extensive line of standard servo motor and servo motor-generator combinations from size 8 - up, a quality group of synchros, and custom-engineered magnetic heads for flight and ground-based analog computers.

For information about Edison precision Servos and Servo Components, write for Catalog No. 3044 . . . your copy is reserved.



EDISON SERVO MOTOR DAMPING GENERATOR

Space Age Definitions Needed by Truckers

To the Editor:

This Bureau is one of eighteen in the larger cities of the U.S. to assist both carriers and shippers in the proper description and packaging of motor freight shipments. Our Bureau recently subscribed to your magazine to help us keep abreast of technical developments in the missiles and rockets field, as well as related developments in electronics.

The National Motor Freight Classification provides a description for "projectile or rocket parts." It is therefore necessary for us to have a few definitions to work from. We wondered if you might be kind enough to help us define and distinguish between the following terms as they are correctly used in the industry: projectile, jet engine, rocket engine, rocket, missile, rocket-missile.

At one time we decided that "projectile" was a general term applied to any article which is moved abruptly into or through the air by any force. This meaning would include a bullet, an arrow, a sone form, a slingshot, a rocket or a missile.

At various times we have considered a "rocket" defined as a projectile driven by a special type of motor called a "rocket engine;" and, in contrast, a missile was propellant without the use of a rocket engine.

However, it now appears, from usage in your magazine and in the industry, that a missile is much the same as a rocket, except that it is always "guided." So, at this point, we are simply confused.

Your help in defining these terms will be appreciated by the whole trucking industry.

C. F. Sullivan,
California Trucking
Associations, Inc.
3301 South Grand Avenue
Los Angeles 7, Calif.

Insofar as possible m/r feels that any definitions in any new field, missiles, rockets and astronautics included, should stick to traditional definitions. A projectile, therefore, is (according to Webster) "a body projected by exterior force, and continuing in motion by its own inertia; specifically, a missile for a firearm or cannon." That definition could also include hurled rocks, arrows, spears and the warhead of a ballistic missile. A jet engine is, in general, any engine based on the reaction principle. Specifically, however, usage restricts it to those engines which carry only fuel and rely on the atmosphere for oxident—axial and centrifugal flow turbojets, pulsejet, ramjet. Briefly, a rocket engine also relies on Newton's third law of motion, except that a rocket carries its own oxident. Missile includes projectile but is broader, including anything that can be "thrown, hurled or projected" whether guided or not—such as pilotless aircraft, for example. Rocket-missile seems to be a redundancy or terminology.—Ed.

Wants Missile Films, Books

To the Editor:

Our management Club, at Douglas Long Beach, is one of the groups needing more information about the missile program. We are starting on the *Thor* ground support equipment and do not have an adequate background in missile science.

In the April issue of m/r you referred to booklets and films by Martin & General Electric. Could you please forward the addresses of those companies so that we can make arrangements for copies of the booklets and renting of the films.

E. E. Brockmann
Douglas Aircraft Co.
Long Beach, Calif.

Contact Tom Irvine, Manager, News Bureau, General Electric Company, Schenectady, N.Y.; and Joe Rowland, Manager, Public Relations, The Martin Company, Baltimore 3, Md.—Ed.

Wants Cover Shot for Framing

To the Editor:

Your magazine has been a source of much pleasure and information to me. I have been receiving MISSILES AND ROCKETS for several months now.

The cover of the June issue, with the space ship heading toward a galaxy, is truly beautiful. Can you send me a photograph or reproduction suitable for framing? I will be glad to pay any charge for this.

Leonard Busbee
1841 New Tampa Highway
Lakeland, Fla.

It's in the works.—Ed.

Says They Come First

To the Editor:

With reference to p. 84, April m/r, while we thoroughly agree with author Fred S. Hunter that Systems Laboratories Corp. has many distinguishing features, one of them is not that it is the first corporate organization specializing in interplanetary flight. We understand SLC was incorporated in May, 1956. The General Astronautics Corp. was incorporated under the state laws of New Jersey in February 1956, three months earlier. The situation is somewhat similar to two rocket companies: New Jersey's Reaction Motors, Inc has a slight edge in age over California's Aerojet.

Ronald C. Wakeford
General Astronautics
Oyster Bay, N. Y.

Wants to Fire 30-Mile Rocket

To the Editor:

You and your staff are to be congratulated on the marvelous job you have done in the compilation of such a great amount of material during the relatively few months that m/r has been published.

I was particularly impressed with the issue featuring "Modern Torpedoes and Underwater Missiles." Back in 1943 thru 1945 I worked on one of the first guided missiles. It, too, was designed to be launched from the air and then to strike its target underwater.

The driving force was a rocket motor. Unfortunately, the project was not completed in time to be effective, and as far as I know has never been released from security.

The Rocket Research and Development Society of Houston, Tex. of which I am technical director, has a problem for which you may be able to give some advice.

This group is very active in the engineering of rockets and missiles and I

HUNTER

HEATING SYSTEMS

FOR MILITARY APPLICATIONS

Hunter heating systems are used for a wide variety of military applications. They are standard heating and winterization equipment for many types of mobile shelters, military engines, generator sets, etc. and are designed to conform to military multi-fuel requirements.

HUNTER SPACE HEATERS

for mobile or portable military shelters, for radio, radar and guided missile control and maintenance installations.

HUNTER ENGINE HEATERS

for starting internal combustion engines at sub-zero temperatures, for trucks, generator sets, air compressors, etc.

HUNTER SPX TORCHES

for a wide range of applications at sub-zero temperatures. An unpowered open flame burner capable of being lighted with a match and operated on conventional fuels at temperatures down to 90° below zero. Capacity range—from 15,000 to 200,000 BTU.

am sure that their efforts in the future will result in more rapid and efficient solutions to the problems that exist in this field.

However, we do not have an adequate firing range where we can accurately check performance. If at all possible, we would appreciate the opportunity of firing our 30-mile missile at some facility equipped for this type of work.

We have already contacted Lt. Col. James P. Hamill, Chief Ordnance Mission at the White Sands Proving Grounds but were informed that the Department of Defense regulations do not allow private groups to use that firing range.

If there is anything you can do to help us locate some facility where we would be permitted to fire our missile under controlled conditions, it would be deeply appreciated.

Ten or twelve boys would want to participate in this firing activity.

See Missile Miscellany, page 168, and write Mr. Foster Haley, Office of Public Information, Redstone Arsenal, Huntsville, Ala. He may be able to help. He'll try anyhow.—Ed.

Subject: Article entitled "Project Vogelhundt"

To: Missiles & Rockets Magazine

1. The attached material was submitted to this office for security review and clearance for public dissemination.

2. The statement in paragraph 1 of the article indicating that the project comes under the cognizance of the Naval Ordnance Test center appears to be in error. NOTC informs this office that while the project borders upon PROJECT SMISH, which, as you know, is highly classified, it in no way overlaps or invades that field.

3. Consequently, the Navy Department has no objection to publication on grounds of security. However, it is suggested that MISSILES & ROCKETS Magazine, in keeping with its policy of obtaining official clearance for its material, submit article to the U.S. Army Canine Corps (QM) and/or the U.S. Air Force Strategic Air Command (Security Division).

4. For your information, it is believed that original research on olfactory processes and particularly on Bassett Male Aero Bark X3A was conducted by Army with technical assistance from the Seeing Eye Dog Foundation. Research on the Mark IV version was taken over by Air Force SAC in connection with its program of security for bases.

5. Early in 1956 it was determined that Bassett Female Yipe 6 and setter Female Yipe 8 appeared to be far more productive than the X3A and Mark IV versions of Bassett Aero Bark and that the end product was less subject to infestation by parasitic bosphoetai. Further and more detailed data on additional expermentation should be obtainable from the two services mentioned.

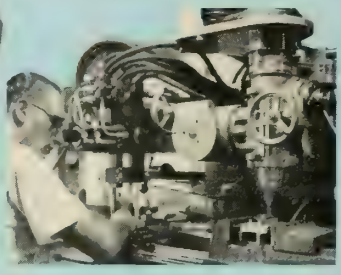
6. Regarding the alleged accidental firing of Project 73, which the article states, landed in the Panamint Range, it is suggested that this matter be referred to the Department of the Interior.

R. A. Barracks
Cmdr. USN
Chief, Navy Branch
Office of Security Review
Office of the Assistant
Secretary of Defense
Washington 25, D. C.

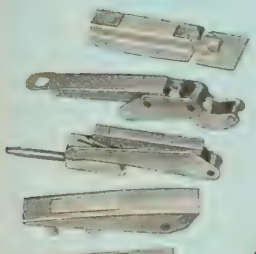
New readers see "letters" in m/r's May issue. Project Vogelhundt was submitted to Department of Defense Security Review, according to a long-standing m/r custom of never publishing any document that we have not cleared. After much serious consideration on the part of those charged with safe-guarding our security, m/r received this "official" clearance from a Navy Commander who (bless him) has a sense of humor.—Ed.

The Challenge of Gravity

To the Editor:



If it were possible to select a best issue from among the fine presentations which the m/r staff has put out every month, my vote would go to the recent June 1957 issue. The article entitled "Seven League Boots" by Seabrook Hull brings to the fore a subject which many have puzzled over but which relatively few have ever put any real effort into: gravity.



Please understand that aside from having the tools of an engineering degree and eight years experience in the consulting field my only familiarity with the subject comes from studying the works of others and a very slight amount of original thinking and calculation.

Being convinced, however, that the key to the great revolution in man's approach to his environment is hidden in the term gravity, it is my purpose to add

PUT HARTWELL TO WORK

INSURING RF SIGNAL RECEPTION AND TRANSMISSION IN THE LOCKHEED X-17 TEST MISSILE

The Rheem REL-09 Miniature RF Power Amplifier has been used in the X-17 test missile since the inception of the project.

The REL-09 provides power amplification over the 215-235 mc telemetering band. With 1.4 watts input drive, it will deliver an 11-watt output to a 52-ohm load. Grid and plate tuning controls are accessible from the front plate. Automatic protection is provided against damage resulting from loss of drive or plate power. Power leads contain 84-db attenuation filters. No cooling or shock mounting is required.

For further information, write direct to Rheem or contact your area sales representative:

letters

whatever meager help I can toward the solution of the mystery.

Not being one of the small group of particularly qualified men, I am interesting myself with the problem of stirring up interest among the larger group. Interest in any subject increases as one's knowledge of the subject increases. Obtaining knowledge on the history of research and development in the field of gravity is not impossible but is time consuming and sometimes rather discouraging. Except for a chapter in a physics text or a very involved mathematical treatise by Einstein most of the material is pretty well scattered.

There is no book available, according to the Massachusetts Institute Bookstore, devoted to the subject of gravity exclusively. I am therefore engaged in the compilation of such a book which I hope will serve as an introduction to the subject to many uninitiated but fertile minds.

The book will not be the presentation of original material but rather will be a review of the study of gravity from the earliest times to the present. It will include as complete a bibliography as possible of all articles and publications dealing with the subject. Excerpts or abstracts from these publications will be included (depending of course on the authors' and/or publishers' permission).

It is hoped that this book will excite the interest and imagination of at least a few capable young people to the point where they will take up the ball and devote their efforts to this problem.

I am fully aware that several well financed projects are currently under way and that they are manned by very capable men. It is my belief, however, that this small task force needs many new recruits to win the battle.

In order to make this book as valuable and complete as possible I earnestly solicit your comments and criticisms as to the undertaking itself and with reference to the type of material which you think should be included. I also request permission to reference your article (with proper credit).

Any information such as possible sources of information or parties who might be willing to assist this project in any way will be sincerely appreciated.

A "well done" to the entire staff of m/r. Keep up the good work.

William S. Alcott
49 Blackhawk Road
South Weymouth, Mass.

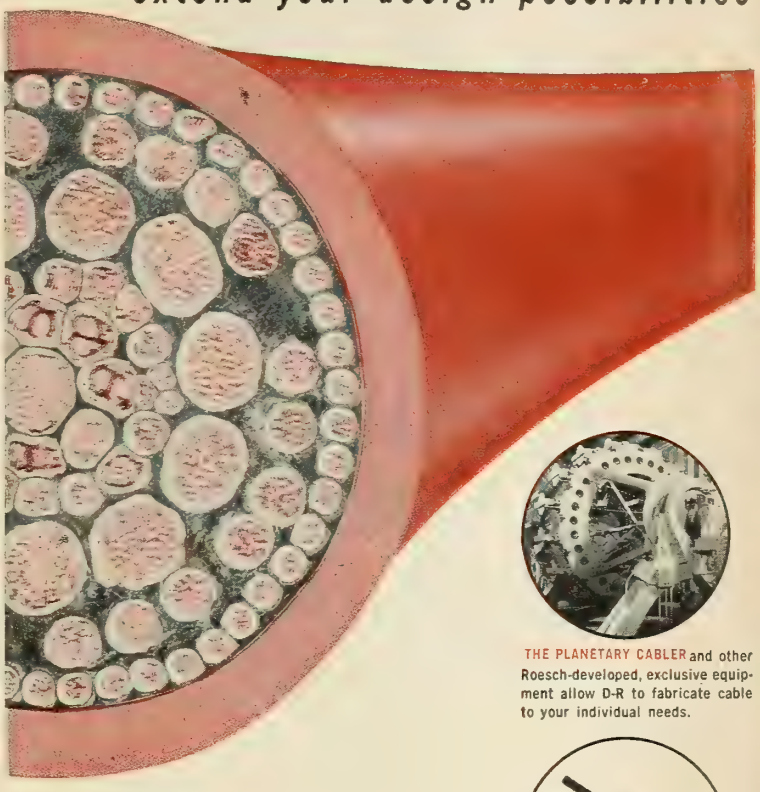
A letter follows. Good luck.—Ed.

Future Missileer

To the Editor:

I could point out more than one reason why I subscribe to your magazine, but they all would boil down to one: My great interest in the subject which is more than anything else symbolic of the world's progess and of the continuous effort to intensify the relations among peoples.

I am only a high school student but next year I will attend Rome University's Faculty of Aeronautical Engineering. I will thus be able to devote myself entirely to this subject.



It is my intention to take up a finishing course and work in the U. S. after acquiring my degree.

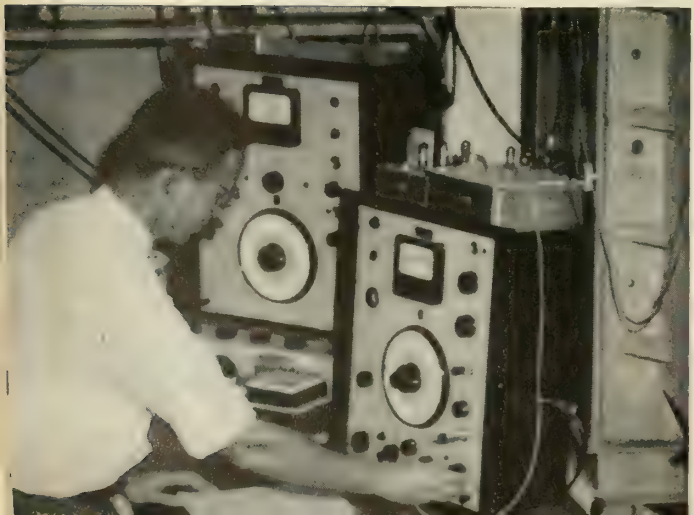
performance test

Brush Recording Systems at Rocketdyne, a Division of North American Aviation, Inc., directly record stress, acceleration, and acoustic values of rocket engines under test.



In all types of applications...

45,000 CHANNELS OF BRUSH OSCILLOGRAPHS IN SERVICE!

When selecting recording instrumentation for either military or industrial research and development, you want equipment that is proved by experience. Remember—there are more channels of Brush direct-writing oscillographs in use than all other makes combined.

This equipment offers the widest range of recording speeds available, to provide excellent readability for a wide range of signals. You have a choice of ink writing or electric writing, available in console, rack mounted or portable units.

The direct-writing frequency range, from d.c. to 100 cycles per second, covers the great majority of requirements for measurement of physical phenomena. Thus you can instantaneously record stress, strain, vibration, torque, force, and many electrical variables. Select *BRUSH* for equipment backed by unmatched experience.

complete frequency spectrum analysis for noise tests

With a Brush-Bruel & Kjaer Spectrum Recorder, a complete frequency spectrum analysis can be performed in a matter of seconds. This instrumentation operates *automatically*—thus saves hours of engineering time. And it presents recorded data in one-third octave steps—a form in which information is most meaningful and useful to noise reduction programs.

Shown at left is an aircraft test setup measuring loss in acoustic transmission through fuselage wall panels. This is one of scores of complete systems for sound, noise, or vibration analysis using Brush-Bruel & Kjaer equipment.

EXHAUST SYSTEMS
FUEL SYSTEMS

Operating Range	Temperature Range (° F.)	Max. Pressure (3" Size @ 70° F.)
Low	−300 to +750	1300 psig.
Medium	−300 to +1000	3300 psig.
High	−300 to +1600	testing still in progress

A 2½" Conoseal Joint has been tested with end restraint up to 6,000 psig.

Conoseal is an Aeroquip Trademark.

Problems of connecting tubing and ducting of dissimilar metals subject to extreme temperatures can be solved with the new Marman Conoseal Tubing Joint. An all-metal joint, it provides metal gasket compression with the flexibility and sealing qualities formerly obtained only through use of organic seals. The Conoseal Joint withstands axial deflections up to 1/16-inch without sacrificing a perfect seal. The seal is maintained under extreme pressures and temperatures even on joints with material transitions, in which steel and aluminum alloy plumbing are joined.

The Conoseal Tubing Joint is available in three different operating performance ranges to meet varied applications. Standard sizes from 1" to 12" O.D. tube size, with special sizes designed to your requirements. Write today for full engineering details.

Open Letter to Industry

Subject: Project R-1
Project R-2

Gentlemen:

Some twenty months ago, our Company as a participating member of the industrial team involved in the Air Force Missile Program, was faced with the need for full scale cold flow testing of large missile oxygen prototype systems. At that time, we undertook an extensive survey to determine the available capabilities both at government and commercial installations for such testing. We found that tight schedules prohibited the possible use of government facilities and no commercial facilities existed. As a result, Cambridge Corporation inaugurated two projects directed toward achieving complete full scale testing capability for liquid oxygen and JP fuel support systems.

These facilities, as described in this folder, are now available to anyone active in the missile program or in the commercial oxygen industry.

Your interest is invited and can be expressed on the reader reply card attached. You may be assured of our whole hearted cooperation and assistance.

Very truly yours,

CAMBRIDGE CORPORATION

J. W. Logan
President

Missile Business

By Seabrook Hull

FOREIGN MARKET FOR U. S. MISSILES in next two years will total $300-to-$500 million. This is the missile build-up phase of the Mutual Defense Assistance Program. Once the pipeline is filled, the maintenance and modernization level-off rate will run about half that.

Nearly every type of U.S. missile is potentially involved. First interest, however, is in air-to-air, ground-to-air, tactical surface-to-surface and Intermediate Range Ballistic Missiles. Main markets are Western Europe, Australia and Japan. In the beginning, direct sales and grants to other countries will be minor.

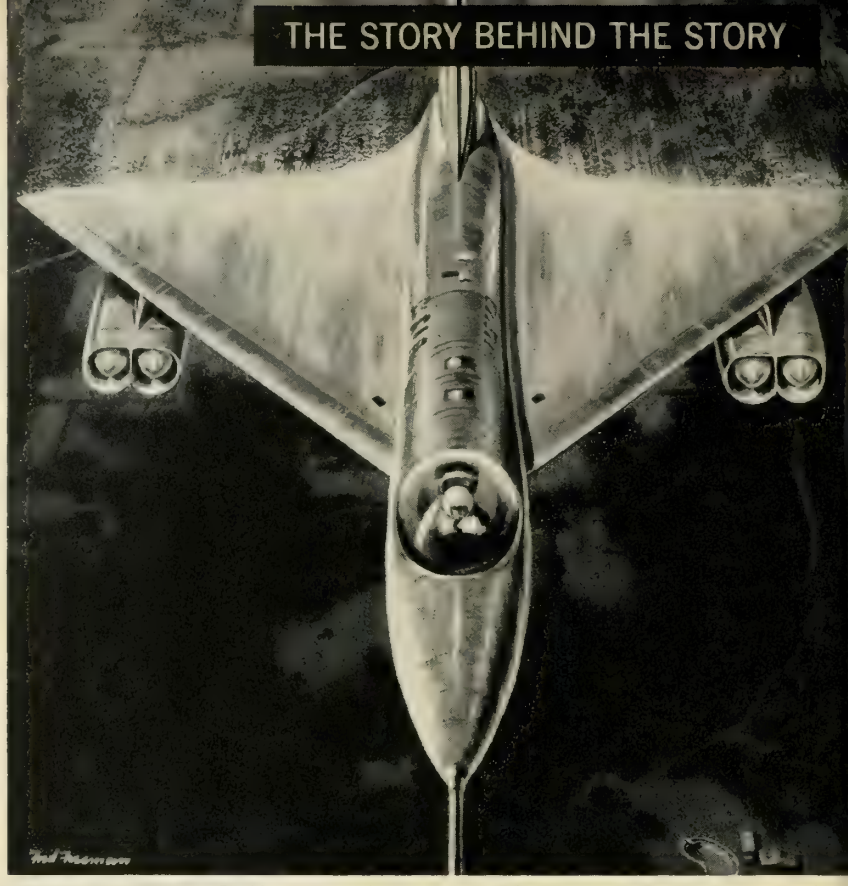
Only real potential competitors U.S. missile-makers face at the moment are Britain and France, and even they won't build big missiles like IRBM's. At this writing, no U.S. missile company plans production abroad. Reason is severe initial capital cost. To a large extent, U.S. sales abroad will involve only the basic piece of hardware plus a minimum of spares. MDAP planners hope for local-country servicing, manning, maintenance and operation. U.S.-supplied nuclear warheads will remain U.S. property under the law but will be stored "just over the fence" from U.S.-made, foreign-owned missiles.

COMPETITION FROM BRITAIN will come primarily in air-to-air and surface-to-air missiles. Here, the British nearly match U.S. in some cases; are ahead in others. British appear particularly hot on terminal guidance, but lag in ground-control techniques. British hope their ability to produce less complex missiles at lower cost will be sales advantage. Foreign buyers are more price conscious than U.S.

AIR FORCE IS WORRIED ABOUT MISSILE COSTS. At recent briefing top AF officials told 100 representatives of 51 major contractors that future business would go where prices were lowest. Maj. Gen. David Baker, AMC Procurement Director, deplored current high costs.

BIG MISSILE NEED IS PRODUCIBILITY. This means taking a tip from auto-makers and other mass production manufacturers. Tendency now of taking an R & D vehicle and ordering it into production substantially unchanged must stop. One answer is to put the manufacturing department on an equal footing with the designers. Another is to improve liaison between designer and producer. Designer's lack of knowledge of optimum production methods and producer's ignorance of design and operational requirements are, generally speaking, appalling.

DON'T WORRY about Defense Secretary Wilson's $38 billion ceiling on defense spending. Object's to avoid a deficit national budget. Treasury Secretaries traditionally over-estimate expenditures and under-estimate tax revenues—Humphrey more than most. The money's there and will be forthcoming if needed to keep missiles on schedule.

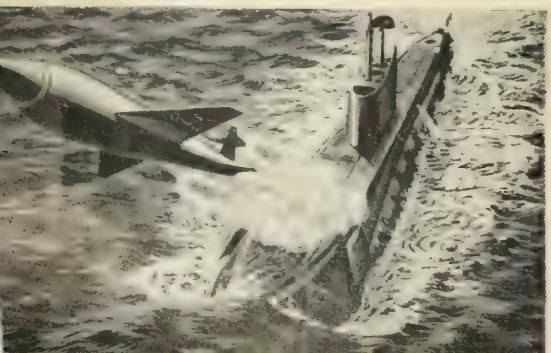


SOME MISSILE PROGRAMS WILL BE CHOPPED, however. White House has ordered end to missile bickering; claims it jeopardizes national security. Result: Wilson has ordered crash review of all missiles, particularly IRBM's *Jupiter* and *Thor*; wants action in 30 days.

SINGLE MISSILE R & D AND PROCUREMENT AGENCY may be result. This probably would mean wedding of AF Ballistic Missile Division and Army's ABMA into single-service R & D operation, not dissimilar to NACA—as suggested first by m/r in January. There are strong views that this should be non-service—neither AF nor Army.

VISIT OF 19 TOP AF BALLISTIC MISSILE EXPERTS TO REDSTONE, including Maj. Gen. Bernard S. Schriever, for complete exchange of technical information may mean IRBM nod for *Jupiter*.

MISSILE CRUISER Problem: To launch a missile 1500 miles from target. An error of only 1 degree in launching information would cause a 25-mile target miss.



SUPERSONIC BOMBER—Problem: To navigate undetected for thousands of miles to exact position in space for release of bombs or missiles.

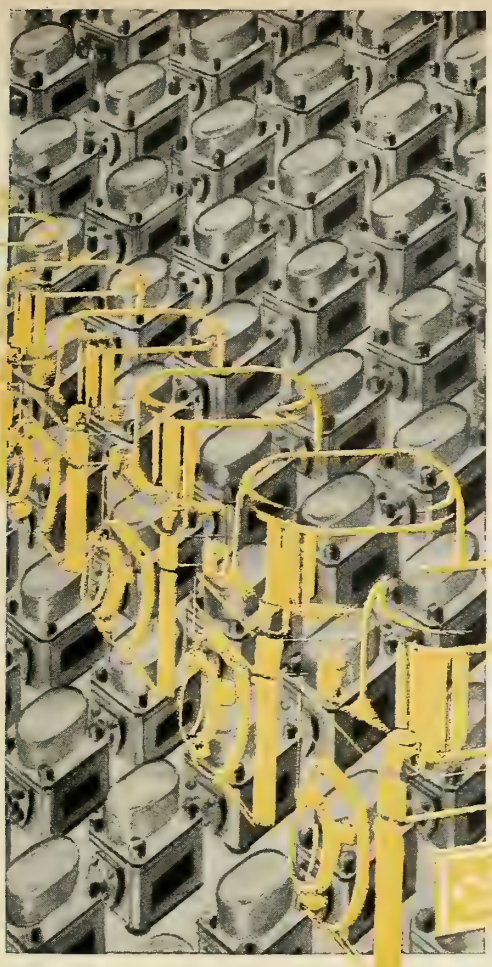
INERTIAL NAVIGATION:

In Its Accuracy Lies Power for Peace

ATOMIC SUBMARINE— Problem: To travel submerged for days and know exact spot to surface for missile firing.

U. S. strategy for maintaining peace by making aggression unprofitable is based on our ability to deliver a crushing retaliatory blow anywhere in the world. Accurate means of directing such blows at long range, high speeds and extreme altitudes make would-be aggressors wary of breaking the peace.

To be effective, weapon carriers must know at all times *exactly* where they are. For example, the long-range bomber with its pinpoint target or the pitching cruiser launching missiles far at sea must navigate with great accuracy.



Solving such problems is the task of Inertial Navigation systems which furnish all data required *automatically*. Completely self-contained within the bomber, ship, submarine or missile, these Inertial Navigation systems require no contact with ground stations. This is extremely important when military missions must be carried on without chance of detection.

To design and engineer Inertial Navigation systems involves a complex combination of engineering skills—gyroscopics, computation, electronics, servomechanics and more. Their production calls for laboratory precision at every stage. For example, the gyroscopes which form the heart of Inertial Navigation systems must be many times more accurate than those used in commercial navigation.

At Sperry, Inertial Navigation systems are being produced for a wide variety of military applications.

Army to Launch Second Jupiter "C"

Army Satellite Tracking System Revealed

HUNTSVILLE, Ala.—An apparent speed-up of test firings at the nearby Redstone Arsenal and ABMA facilities in recent days has led to speculation that a second version of the *Jupiter "C"* is being rushed to completion.

The rumblings and subdued roars of tests from the huge stands at the arsenal have become longer and louder during the past few days, surpassing anything to which local citizens have become accustomed during the past five years. The tests can usually be heard in the city, several miles away, during mid-afternoon. Occasionally there is a second test in the late afternoon. They usually can be heard for about one minute.

In early June, one test began at about 4:30 P.M. but it ran more than twice the "normal" length of time. One citizen who timed it said the final cut-off occurred 162 seconds after the first sound was heard.

The first *Jupiter "C"*, an experimental stage-rocket device consisting of a *Redstone* booster and two stages of clustered solid-propellant rockets was fired last September from Patrick AFB, Florida. Reportedly the missile traveled 3,300 miles and reached a peak altitude of between 650 and 680 miles.

A small payload containing a radio transmitter and other instrumentation was supposed to have been tracked "all the way." Reliable sources say the first *Jupiter "C"* could have brought its payload into an orbit if the final stage trajectory had been preset accordingly. Apparently, the final stage of the *Jupiter "C"* brought the payload down in a powered trajectory rather than in a ballistic path.

The *Jupiter "C"* test vehicle was developed by the Army and Jet Propulion Laboratories to study missile staging and separation techniques as well as guidance, telemetering feedback and tracking.

Some sources have hinted that the second *Jupiter "C"* might put its payload into an orbit around the earth when it is fired shortly. The Army is interested in proving that they are capable of supporting any satellite experiment with current Army hardware. The first artificial satellite project undertaken in this country under the code name "Project Orbiter" was to have used the *Redstone* missile as a first-stage booster and a cluster of *Loki* solid-propellant rockets as the second stage. The project was cancelled when the Government announced Project *Vanguard*.

The Army's own satellite tracking system was put on display at the recent National Telemetering Conference in El Paso, Texas as the subject of a display sponsored by Jet Propulsion Laboratory.

Designed by JPL, the tracking system is known as Microlock. Main features claimed are ultra-high sensitivity, light weight and long life.

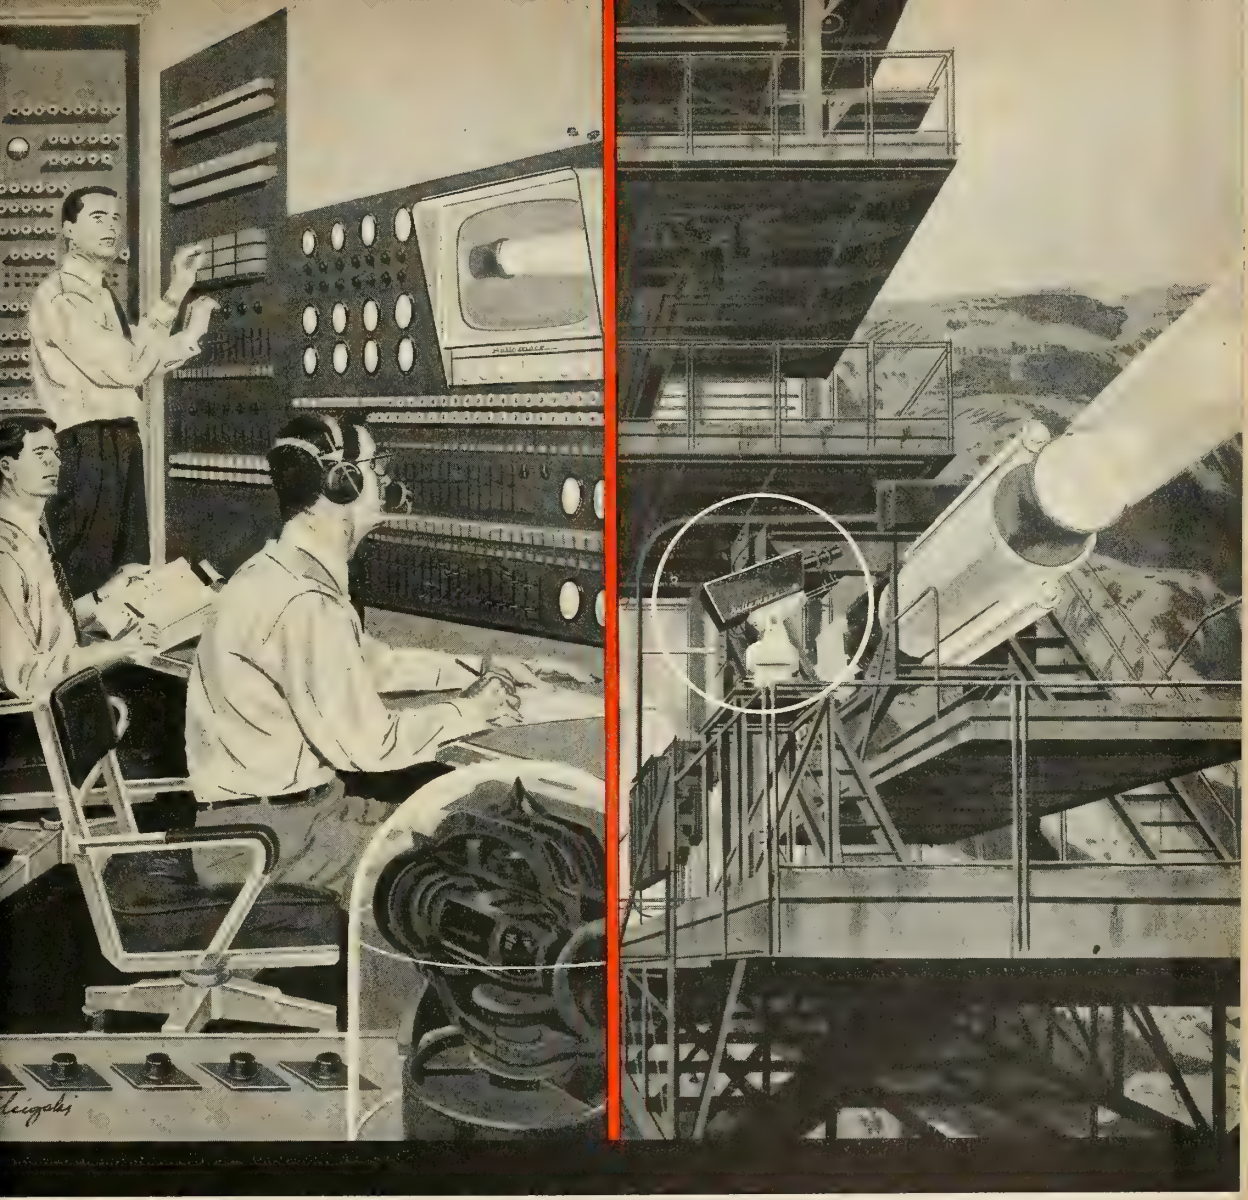
A transmitter for satellite use is contained in a small cylinder and will radiate a signal for three months and weighs 2 pounds. It provides two narrow band telemetering channels.

Tracking for a distance of 3000 miles using Microlock "at any azimuth or elevation angle" is claimed. Reportedly, JPL's satellite system was used in the altitude and distance record breaking flight of Army's first *Jupiter "C"*. Signals from JPL's electronics on board were received to point of impact.

Production of Microlock systems for Army use as beacons in missile testing is under way at Motorola, Inc.'s Military Electronics Division in Phoenix, Arizona.

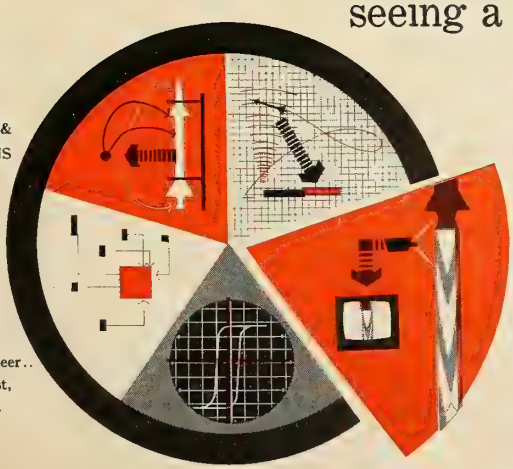
USAF Assumes Responsibility For ABMA

HUNTSVILLE, Ala.—The Air Force and the Army may have buried the hatchet in their bitter *Thor-Jupiter* IRBM dispute as the result of the visit here June 19 and 20 of Maj. Gen. Bernard A. Schriever, commander of the USAF's Air Research and Development Command's Ballistic Missile Division.



The Air Force assumes financial responsibility for IRBM work at the Army Ballistic Missile Agency as the government's fiscal year of 1958 begins on July 1st.

Schriever and a large staff of USAF missile officers visited with ABMA commander, Maj. Gen. John B. Medaris, toured the complete ABMA and Redstone Arsenal installation, watched the work on the Army's *Jupiter* IRBM and saw test firings. It was Schriever's first visit here.

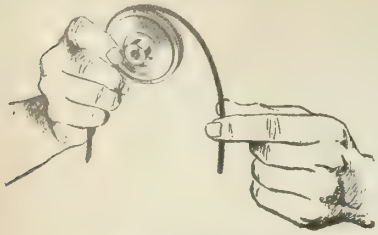


There has been persistent rumors that USAF officers had previously been denied full briefings on the *Jupiter* by the Army, but this was denied by both services.

A brief communique issued by Schriever and Medaris said:

"There has been a complete interchange of technical information in the IRBM developments between the Army and Air Force commands responsible for them. The sole interest of both services is to provide the best IRBM at the earliest practicable date, in the urgent interest of national defense. It is to achieve this objective that we have committed all the resources in manpower, facilities and funds provided for the purpose. Out of this joint effort will emerge the weapons system determined essential to the security of our country."

seeing a hot one...on Hallamore captive T



Far too hot, and positively too ear-splitting, for close, on-the-spot observati by human beings...when high thrust propulsion units are fired up for test, Hallamore closed-circuit television takes over the job. Throughout industry similar Hallamore systems are finding application...wherever the requirem is for remote observation or for fast transmission of visual impressions. Hallamore Electronics designs, develops and manufactures missile ground support and in-flight instrumentation systems, magnetic products, electroni components and audio visual communications systems. HI-TEMP
MECHANICAL FEEDBACK
CONTROL LINKAGES

The unusual cable shown above is Teleflex—the unique "flexible rack" that is helping to solve mechanical motion problems up to 1,000°F.

Take an example in the jet engine field . . .

PROBLEM: A highly accurate mechanical feedback linkage is required to complete a servo system loop. One end of the system is exposed to a 350°F ambient temperature.

SOLUTION: A special control box was designed, with a hobbed wheel to engage the Teleflex cable. A spring-loading feature allows for a selection of spring loads up to 25 pounds, applied in either direction, depending on the individual mounting arrangement or system load. One system over 100 inches long, with 270° of bend, had only .022 inches of backlash. Under more favorable bend and length conditions, another system held backlash down to .005, using a similar control box.

Teleflex tubular conduit, routed along contours and around obstructions, guides the cable to remote locations, duplicating the motion at both ends of a system.

DESIGN ENGINEERS—Complete descriptive information is in Catalog 500 L. Write for your copy to Teleflex, Incorporated, 125 S. Main St., North Wales, Pa.

Second Atlas Ready to Go Next Month?

M/R has learned reliably that the second *Atlas* ICBM is scheduled to be fired at Patrick Air Force Base next month. This is a positive indication that the present state of the *Atlas* development program is proceeding on or ahead of schedule.

Some sources felt that the recent firing was made under pressure in order to expediate the state of the art evaluation of the nation's top priority program. The recent highly publicized misfires of the *Thor* and *Jupiter* IRBMs has led the uninformed press and the public to the conclusion that our long-range missile program is in serious trouble. Scientists and engineers close to the U.S. missile program since its inception shortly after World War II are not alarmed.

Many of this country's missile projects have suffered from growing pains similar to those of the *Atlas*, *Jupiter*, and *Thor*. No informed citizen would have quibbled over the setbacks and costs of the atomic Manhatten Project. Yet, our position in developing the ICBM is the same as with the atom bomb: national survival is at stake. In the latest analysis the first *Atlas* launching was very productive, yielding a wealth of data invaluable to the follow-up flights.

Air Force officials have disclosed that the *Atlas* misfire was due to a malfunction of a propellant turbopump. The numerous pre-flight checks and static firings proceeded with only minor difficulties. Testing began the day before the firing and continued throughout the night. Faults in circuitry check out were corrected with minimum delay. Flight program called for test of the two 100,000 lb. thrust booster rocket engines with a calculated range of over 2,000 miles climbing to an altitude of approximately 400 miles.

Engine ignition functioned perfectly and the *Atlas* lifted in vertical ascent with the twin booster engines thrusting equally. At an altitude of approximately 8000 ft. the flow of propellants to one engine was disrupted. The unbalanced thrust resulting from the enequal burning threw the missile into a yaw with a resultant loop. Guidance control responded instantly and corrected the *Atlas* to its vertical attitude. This maneuver was repeated twice more before decision was reached to activate the destructor system. At the time of destruction the missile was earthward bound with a possible impact upon the launching site.

Convair, North American's Rocketdyne Division and General Motors AC spark Plug Division are to be commended for the smooth handling of the preparations and launch of the expediated *Atlas* firing. Investigation of the history of prototype liquid propellant rocket firings uncover a record which clearly pinpoints a high percentage of failures. The probability of failure increases when pressure is exerted upon designers, production and test personnel.

The Air Force has announced that large scale testing of the *Atlas* ICBM will get under way next fall indicating that the 100 ton missile will be rolling out of the Convair plant on a quantity production basis. Additional tests will probably be run on the booster configuration before a three-engined maximum range will undoubtedly be conducted during the tests this fall.

Air Research & Development Command revealed that six specially equipped tracking ships will be stationed in the South Atlantic to fill in gaps extending out along the planned 5000-mile range. The ships will be positioned over the ocean extending from the last Caribbean station on the island of St. Lucia to the station on Ascension Island.

The ARDC statement confirmed the reports that the *Atlas* firing program will proceed on schedule. The launching of the *Atlas* was notification to the world that the ICBM program has come a long way. The coordinated efforts of the Armed Forces and American industry has proved many times in the past that any technological challenge can be met.

AF Officials Check ICBM Engines

Brig. Gen. B. I. Funk, deputy director, Ballistic Missile Office, made his first inspection recently of the new North American Aviation rocket engine factory and test station at Neosho, Mo. He was accompanied by Col. Samuel Bishop, Col. Sherman Ellis and Col. Albert Shumsky, chiefs of procurement, production and logistics in the BMO at Inglewood, Calif. The Air Force officials were briefed on the progress of construction and production at the Missouri facility by C. W. Guy, assistant general manager of Rocketdyne; J. P. McNamara, Neosho plant manager, and E. A. Wright, factory manager.

SAC Officers Briefed On SM-62 *Snark*

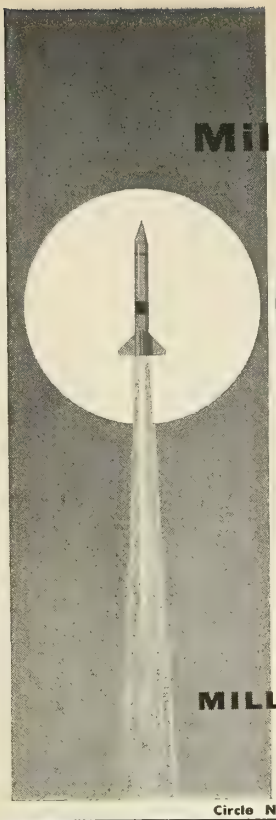
A series of four special courses on the *Snark* SM-62 is being given to key officers and civilians from Strategic Air Command units across the country, including the headquarters at Moffett Air Force Base, by Northrop Aircraft's training services section at Hawthorne, Calif. Selected representatives from the Air Training and Air Materiel Commands also are taking the training.

Program is designed to familiarize the group on the overall weapon system, including the missile, ground support equipment, depot operations, field service, mission, planning, publications and training. Instruction is aimed to provide a knowledge of the *Snark* from an administrative standpoint.

Beech Unveils Reconnaissance Drone

Beech Aircraft has taken the lid off its Model 1013 combat reconnaissance drone which is adapted from the company's model 1001, Navy XKDB-1 target plane.

Designed for airplane or ship launch, Model 1013 is powered by a 110-hp McCulloch engine. It grosses 800 lbs, has an operational speed of 260 mph and a service ceiling of 22,800 ft.



Beech said that first free flights of the XKDB-1 were made recently at the Navy Air Missile Test Center. It is currently undergoing contractor development testing to evaluate performance, radio guidance and recovery characteristics. It is propelled by a 120-hp McCulloch engine, has a speed of 320 mph, ceiling above 40,000 ft. and grosses 600 lbs.

Titanium Price Cut 10% by TMC

Titanium Metals Corp. has announced a 10% cut in the price of titanium products effective June 3 and applicable to a large backlog of orders of aircraft, jet engines, guided missiles, chemical process equipment, electronic and ordnance equipment.

The reduction is an across-the-board average, varying with the product. Commercially-pure sheet and strip are down $1.50 a pound; plate, 50¢ to $1.25 a pound; bar, 95¢ a pound; billets, 85¢ a pound; wire, $1 a pound.

Extrusions are down about 12% or $1.90 a pound. Titanium powder is reduced from $10 to about $8 a pound.

LIQUID OXYGEN and NITROGEN UNITS

For In-Plant Storage and Transportation

Model 48-500 Liquid Oxygen — Nitrogen Unit

These low-loss storage and transport units are skid, caster, wheel and trailer mounted and are available in capacities to 3500 gallons. Larger vessels for bulk liquid storage are sized to 10,000 gallon capacities. All units feature standard equipment as follows: bottom fill and discharge line, top fill line, liquid level gauge, vacuum valve and filter, thermocouple vacuum gauge, pressure gauge, A.S.M.E. code stamped inner vessels, quick pressure build-up system, extended stem valves on liquid lines, ending with Hofman quick couplings.

U.S. Army Building 2000-Mile Missile

The Army may not be allowed to use them, but nobody has said catagorically that they can't build them. So Army's going ahead researching and developing a whole family of solid and liquid propellant missiles, ranging from small tactical stuff like *Honest John*, *Little John* and *Lacrosse* to 300-mile *Redstones* 1650-mile *Jupiters* and 3300-mile *Jupiter-C* test vehicles.

In addition, however, the Army Ballistic Missile Agency at Redstone Arsenal, Huntsville, Ala., is filling some gaps. Reported to be among the gap-fillers are a 2000-mile range Thiokol solid propellant ballistic missile nick-named *Big "B"* (Bee?) and a 750-mile missile possibly called *Little "B"*.

This work is significant in more ways than one. First of all, it's good evidence that the Wernher von Braun team of Army missile-makers hasn't let the furor of the AF-Army missile squabble deter them from the primary task at hand—to make bigger and better missiles and to thus pave the way to space flight.

Secondly, the Army which has traditionally favored liquid propellants for long range missiles, is suddenly turning to solids. This is proof of Redstone Arsenal's acceptance of the progress made in this field in recent months. The advantage of solid propellants for service missiles is obvious. Support equipment required in the way of LOX generators, liquid fuel carriers, etc., is less. There is also possible a greater state of readiness with solid propellants. The problem, of course, is stable storage for long periods.

Both *Little "B"* and *Big "B"* are in the prototype hardware construction stage. All reports indicate they are being developed as weapons rather than as research or test vehicles. Though these programs were probably conceived, approved and given tentative funding prior to the issuance of Defense Secretary Wilson's famous November Memorandum, the fact that the Army is continuing their development implies: First a faith that Army will ultimately be given operational authority to use them; and second, that the Department of Defense is aware of the projects and has okayed them.

It is perhaps ironic that the Army should now be going ahead full blast with the development of solid-propellant long range missiles. It was the alleged Navy reason for withdrawing from the joint Navy-Army *Jupiter* project that the liquid propelled *Jupiter* just wasn't suitable for shipboard operations. A 2000-mile ballistic missile such as *Big "B"* would have greater range than the first-planned models of the Navy's Fleet Ballistic Missile, *Polaris*. First models of this are to have the conventional IRBM range of 1500 nautical miles.

It may well have been the engine for this that a Thiokol spokesman was referring to a short time back when he indicated that his company was working on a solid-propellant motor with a thrust of over 300,000 pounds.

One thing seems certain. If a solid-propellant missile of this nature is forthcoming within the next year it will certainly raise serious doubts as to the feasibility of going into heavy production on the operationally less flexible liquid-propelled *Jupiter* and *Thor*.

LIGHT BENDER!

This 24-inch F/4 lens has a 6-inch diameter entrance pupil, covers a 9x9 inch plate, and yet fits into a 3½-inch shutter!

The trick was to design a lens that could bend the light accurately through such a small shutter, to take advantage of its economy and high-speed action.

It took some doing, but we developed and are now manufacturing in quantity a new PAXAR aerial reconnaissance lens for the USAF that seems to please everyone in on the project.

We'd like to help with your optical problems, too, in all spectra, for either air or ground applications including instrumentation, photographic, IR and missiles systems. We have the largest independent facilities on the West Coast including R & D, as well as prototype and quantity production of glass and plastic elements or lenses.

Give us a call.

SAFE FLIGHT LAUNCHING

WITH CANNON HIGH-RELIABILITY PLUGS

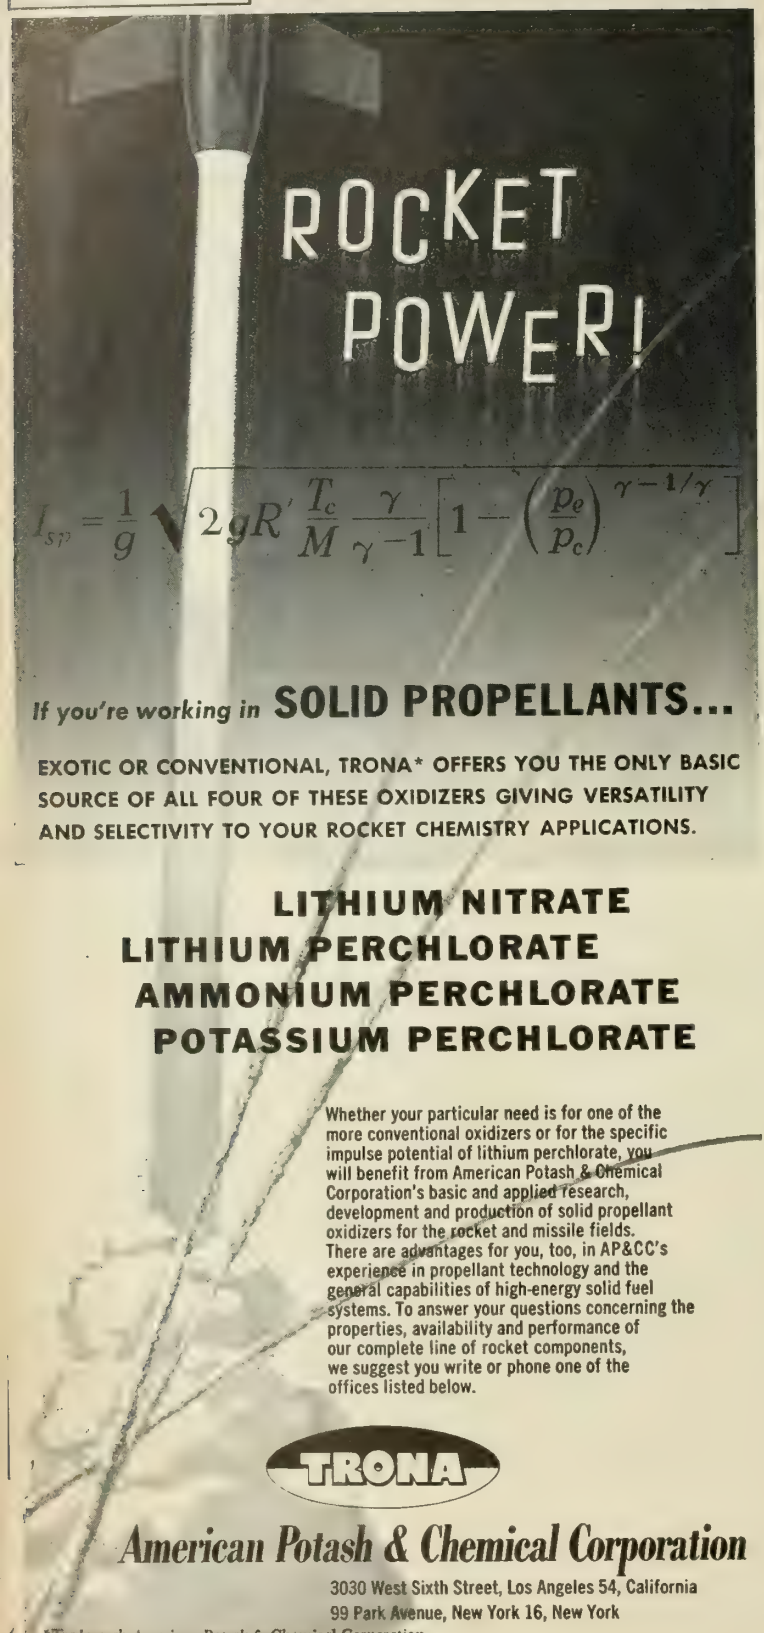
Performance of missile launching connectors cannot be "hit or miss." Both safe launching and safe flight are required. And that's where Cannon's reputation for quality and design experience can help... with the most complete and most reliable line available.

Through proper care, analysis, and control, our Cannon organization can furnish missile quality to any AQL desired!

Cannon Missile Connectors have been developed to meet the specialized demands of the guided missile program. They are available in a number of basic shell designs built for heavy duty service, with a variety of different materials available as inserts. More than 22 contact layout arrangements accommodate from 8 to 140 contacts. Coaxial, thermocouple or high-current-capacity contacts also available.

For complete information write for Bulletin on Guided Missile Connectors... or contact our factory engineers for assistance in solving your particular problem.

Missile System Connectors... For Safety in Flight



Thousands upon thousands of Cannon "standard line" connectors are being used today in missiles of all types. They are noted for the "something extra," the quality, and the reliability Cannon builds into each and every one. More than 27,000 different items to meet your every need. For a brief introductory coverage, write for the New Cannon Plug Guide, Bulletin CPG-3.

Cislunar Aspects Checked at ARS Meeting

Utilities to be derived from cislunar operations were described by Krafft A. Ehricke, assistant to the technical director of Convair-Astronautics, in a space flight paper presented before the semi-annual meeting of the American Rocket Society in San Francisco.

These pertain to terrestrial observation, terrestrial communication, arrival from Venus or Mars, interplanetary communication and tracking by obtaining adequate baselines and to cislunar as well as lunar research. Even a vast television show—receivable on home sets—is a prospect.

The three-day gathering was held under the auspices of the northern California section of ARS in conjunction with the 1957 semi-annual meeting of the American Society of Mechanical Engineers, and the dual program attracted a large attendance. Feature events included a dinner at which Rear Adm. W. F. Raborn, director of the special projects office of the Bureau of Ordnance, was the speaker and a luncheon addressed by Dan A. Kimball, president of Aerojet-General Corp.

Missiles will continue to be a subordinate weapon for aircraft carrier task groups during the next 10 to 15 years, Adm. Raborn declared in his talk. Both air-breathing guided missiles and long-range ballistic missiles can play important supporting roles, he said. They can "shock" and largely neutralize the enemy air defenses in any kind of weather, and thus open the way for the attack by carrier-based manned aircraft, he declared.

Aerojet-General hopes to get underwater rockets up to speeds of 300 to 400 mph, with extended range, Kimball reported. He also assured his listeners that "real good progress" is being made on intercontinental missiles.

The effect of lunisolar perturbations on high observational and communications satellites, likely to be located from 3 to 10 Earth radii out, is very small and may be disregarded for most purposes. In the same region, terrestrial perturbation due to the Earth's asphericity is greatly reduced compared to the effect on low-altitude orbits. This transition zone, where the amount of perturbation from either source is particularly small, Ehricke calls a "zone of quiet." In this zone near-circulatory orbits are particularly stable.

If chemical space vehicles are to be used for manned interplanetary mis-

Circle No. 54 on Subscriber Service Card.

sions, Ehricke propounds the advantages of a captured satellite orbit at about 15 Earth radii out for the return trip from Venus or Mars. Less energy would be required than at closer distance from the Earth. The space craft would remain occupied only for a comparatively brief period of time.

As soon as their final orbit is accurately known on the ground, a relief vehicle would be sent up to transport the interplanetary crew down to earth. Ehricke points out that for vehicles with very high specific impulse, such as ion-powered vehicles and perhaps others, such complications would not be needed.

Farther out in cislunar space, lunisolar perturbation increases, but even at 20 Earth radii is not prohibitive for transponder satellites of what Ehricke calls a "terraluna antenna system" for interplanetary tracking and communication.

Thiokol's Utah Test Facilities Operating

Static test facilities at Thiokol Chemical Corp.'s new Utah Division are operating. Production facilities at the location are slated for completion in the fall.

Five-Stage Rocket Proposed By Truax

The increased use of rocket power plants with as many as five stages may require a look at some fields that were passed over.

Navy Commander Robert C. Truax, president of the American Rocket Society, and currently on special duty with the Ballistic Missile Division of ARDC, told members of the First Helium Symposium sponsored by the Aeronautical Division of Robertshaw-Fulton Controls Co., Anaheim, Calif., that "we cannot continue leaning blindly on tradition."

"We need a new kind of rocket for successful multi-stage rocket development, and we may be required to stop the chain of evolutionary development and take a different tangent," Truax declared.

Latter stages of a rocket power plant are subject to environmental conditions considerably different from those of the initial stages, such as a lack of back pressure, the direction of the gravity vector and the accompanying effect on performance. It was suggested that a re-examination and re-evaluation of optimum chamber philosophies may be the key to simpler and lighter latter stage design.

One suggested solution was a reduction of chamber pressures from what is currently considered optimum for overall rocket design. By reducing these pressures two major gains could be made: a savings in weight and a reduction in heat flux densities.

The reduction of heat flux density requires lighter and simpler construction, permitting use of thinner materials and the possibility of adapting modern welding techniques for ease of fabrication. It may also be possible to eliminate the turbo-pump entirely by using a pressure-fed system and chamber pressures on the order of two atmospheres absolute.

Lower feed pressures will reduce thrust and, as the flow rate decreases, the bulk coolant temperature will rise and tend to boil. Although this has been considered a somewhat undesirable condition, it may be allowable if chamber pressures go down.

show we can't, and some recent data shows we can," said Commander Truax.

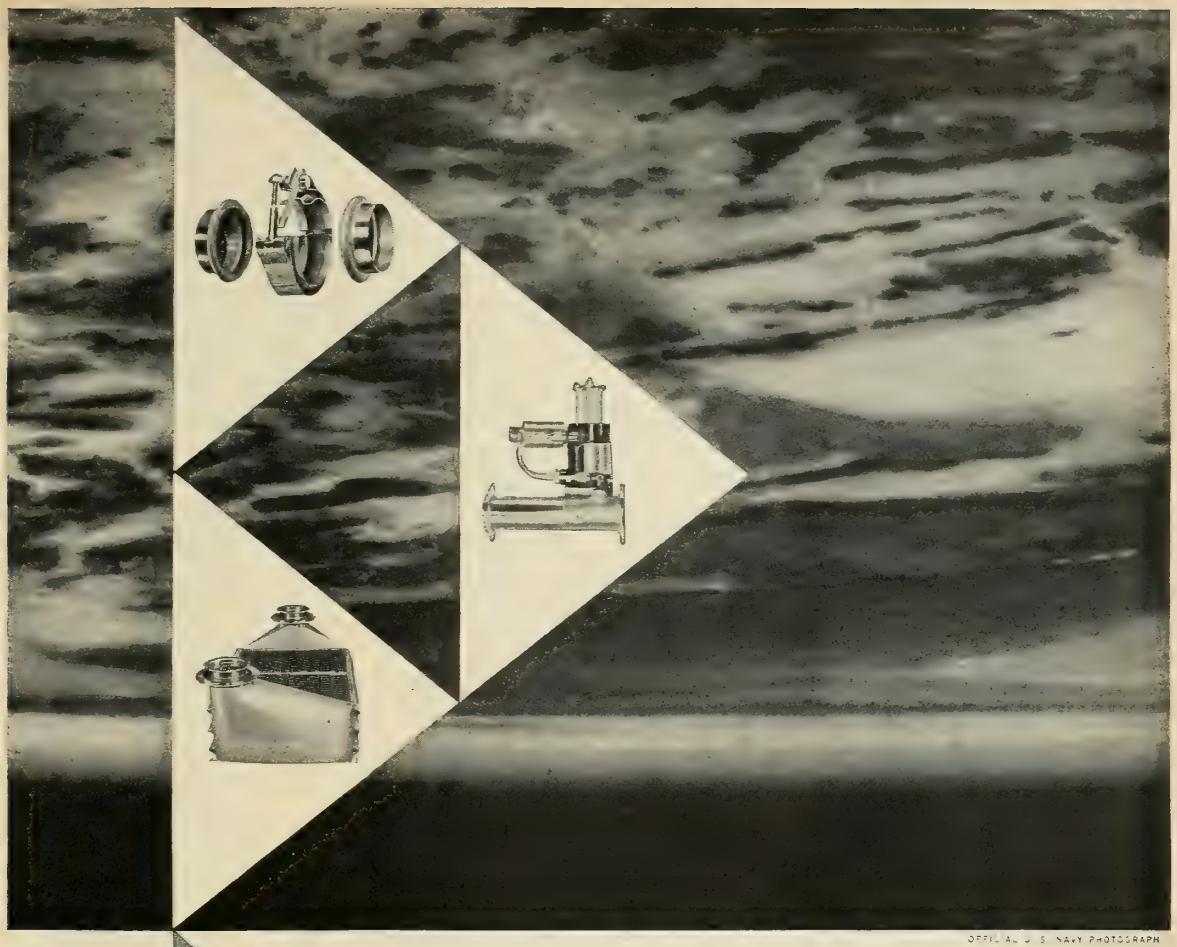
Described as wet steam, the product of bulk boiling might be difficult to meter and may create a problem in control of mixture ratios, but as it may also flash into vapor during downstream flow, the possibility of utilizing atomization in place of impingement velocity should be considered.

The reduced thrust which would result in a latter stage rocket designed around the possibility of lower chamber pressures, plus the gravity loss increases, would become less important and might be resolved by extending the burning time. If the vehicle can be made smaller, the thrust/weight ratio may become unimportant.

In conclusion, Truax suggested that a program of research and development in boiling heat transfer is needed. He again stressed a scrutiny of optimum chamber pressure valves as an approach to the simplification and weight reduction of latter stage rockets.

Another speaker, William H. Lawrence, chief of the Mechanical Section at Edwards Rocket Base, Calif., told symposium members that "the rocket industry will grow to a large extent on the adequacy of gas component design."

Discussing the subject of "Operational Helium," Lawrence declared that a re-evaluation of philosophy of system operation is seriously needed.



He pointed out an apparent lack of suitable high-pressure relief valves as existing components "either leak or start seeping several hundred pounds prior to relieving," and described the use of burst diaphragms at the Edwards Facility to prevent this.

Lawrence predicted an increase also in the use of liquid helium because of advantages in transporting, storing, and pumping which enable a large-scale user to handle a moderate quantity of the liquid and "do the same job which now requires an all-out effort with 'railcars' of K-bottles."

Firebee Achieves 14-Flight Record

Ryan *Firebee* "Drone 1518" has been parachute recovered 14 times in the desert at Holloman Air Development Center, N. Mex.

The drone, according to Holoman officers, has averaged more than 40 minutes per flight since it went into service Jan. 9, 1956, and has streaked at high subsonic speeds for more than an hour on three of its flights.

OFFICIAL U. S. NAVY PHOTOGRAPH

three Janitrol® answers to exciting new problems!

Janitrol couplings for bleed air ducts provide positive metal-to-metal seal, are easily installed in tight spots, stay pressure-tight after repeated disconnects —and in addition give lowest weight per coupling yet achieved.

Janitrol pneumatic valves and regulators bring new versatility, light weight and dependability to air distribution systems for tank pressurization, canopy seal, and other vital air-powered devices.

Janitrol Platular® heat exchangers combine the efficiency of tubes, the strength of plates, and the simplicity of modular construction. They offer new compactness, high performance, and freedom of design in restricted spaces.

If your company is making major investments in jets and missiles for the future, Janitrol's resources can serve you well. They have carried a broad range of aircraft hardware out of the design stage into proven realities. Your Janitrol representative invites your inquiry . . . Janitrol Aircraft-Automotive Division, Surface Combustion Corporation, Columbus 16, Ohio.

ENGINEERS · SCIENTISTS

"We're developing the Atlas ICBM ...giant step toward Outer Space!"

DR. HANS B. FRIEDRICH
Assistant Chief Engineer – Development of CONVAIR-*ASTRONAUTICS*, received his Ph.D. at the University of Leipzig, and was the co-developer, with Dr. Wernher von Braun, of the famous V-2 rocket. He is responsible for directing the research and technical development of the Atlas ICBM.

"The Atlas Intercontinental Ballistic Missile, now being designed and developed by CONVAIR-*ASTRONAUTICS*, will be, for a time during its flight, a true space vehicle. At hypersonic speeds, it will travel hundreds of miles beyond the earth's atmosphere.

"That's why our top theoretical scientists here at CONVAIR-*ASTRONAUTICS* are exploring every implication of flight into space. Even now these men are thinking in terms of multi-stage rocketry, re-entry, solar propulsion and cosmic dust bombardment. Other teams of our engineers and technicians are engaged in the practical application of this new science, Astronautics.

"Our first job here at CONVAIR-*ASTRONAUTICS*, of course, is to make the Atlas ICBM operative, for we are aware that this is a top priority weapon. You – as an engineer – can appreciate the stimulating atmosphere generated by a project so vital to America's defense.

"As a graduate engineer or scientist with an aptitude for creative thinking, your future is with CONVAIR-*ASTRONAUTICS*. Here you will associate with the leaders in this advanced field – work in our new $40,000,000 facility. You will see and feel the kind of achievement that means personal progress. And you will enjoy living at its best in beautiful, smog-free San Diego.

"For your future's sake, write today to: Mr. G. N. McMillan, Engineering Personnel, Dept. 77-H."

New ICBM Data Telemetry Process

ICBM nose cone data acquired from flight tests are being fed back to General Electric Co.'s engineers 300 times faster than previously possible.

A unique automatic data processing facility installed at the GE Missile and Ordnance Systems department in Philadelphia has just been installed as an aid in the technological race to perfect the ICBM nose cone.

Harry Rosen, manager of the facility, said schedules calling for a maximum of 3-4 days to process 300 types of information telemetered back from a typical nose cone test could not be met by usual data handling methods.

An IBM 704 machine was chosen together with automatic analog and digital conversion machines and switching equipment to do the job. Many of the machines were designed by GE for the purpose.

Tapes containing information from nose cone tests run by various government and industrial organizations is sent to GE. Computations and graphical reports are then made up in record time for GE's 1100 engineers and scientists employed by the Missiles and Ordnance Department.

Autonetics Boosts Film Production

Autonetics division of North American has established a separate motion pictures unit and Jay E. Gordon, formerly supervisor of the motion pictures unit for both the Autonetics and Missile Development divisions has been named supervisor of the unit. He is assisted by Walter V. Hardy, in charge of professional and administrative services, and John D. Rogers, who heads the unit's production and technical services.

Autonetics has more than 30 motion pictures currently scheduled for production this year.

m/r Gets New Editor To Cover Red Missiles

Under its editorial expansion program, m/r is pleased to announce the addition of Dr. Albert Parry to its staff of contributing editors. Dr. Parry is Head of the Department of Russian Studies, Colgate University, Hamilton, N. Y. He will provide m/r readers with constant coverage of missile developments behind the Iron Curtain. Dr. Parry will have a regular column, Behind the Curtain (see page 67), as well as periodic feature and news stories.

ARO

for advanced know-how in

CRYOGENIC
EQUIPMENT

Aro is proud to announce completion of a new Cryogenics Center . . . to meet the challenge of "ceiling unlimited" for applications of low temperature equipment and accessories. With this new technical headquarters and plant, Aro provides outstanding modern facilities for work in Cryogenic Equipment for missile and airframe applications.

Advance Steps by ARO!

- Thoroughly trained engineers and physicists in Cryogenics.
- Fully equipped laboratory facilities for low temperature development and studies.
- Unlimited manufacturing facilities to produce products on schedule and in quantities.
- Trained field engineers for liaison work between customer and factory.

Aro has proved its leadership in the field of Cryogenics. Let us help solve your Cryogenic Equipment problems. Write, wire, or phone.

U.S. Army is Confident of Future ABMA Role

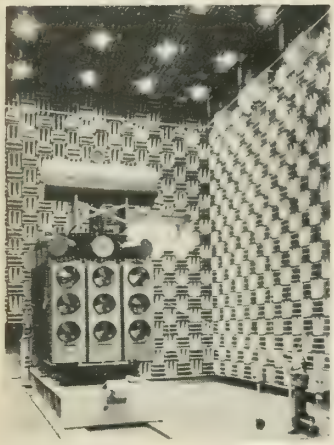
HUNTSVILLE, Ala.—With the Air Force assuming financial responsibility on July 1st for a considerable part of work on the IRBM at the Army Ballistic Missile Agency here, the Army itself is smarting more from what it considers "blows to its prestige" than from fear of any appreciable cutback in funds or manpower for continued research and development of missiles and rockets of every variety and range.

Most of the top officials concerned, m/r found, were little disturbed by the furor that has resulted from the dispute over the Air Force *Thor* and the Army *Jupiter*, both IRBMs.

That battle is still on and now the Army has challenged the Navy over who can make and fire the best earth satellite. Published reports indicate that to date four *Jupiters* and three *Thors* have been launched. All the *Thors* are reported to have failed. Two of the *Jupiters* are said to have achieved remarkable results, one reaching a distance of 1,650 miles.

The Army has been extremely agile in announcing the results of the *Jupiter* tests. The Air Force has said little or nothing about the *Thor* except that the missile has a "production configuration," presumably with fins.

A fifth *Jupiter* may have been fired by the time this article is in print. The most successful Army missile to date is supposed to be the *Jupiter "C"*. This alphabetical designation, however, does not mean that it was the third to be launched, and this missile is actually a *Redstone* with two additional solid-propellant stage rockets.



If anything, the importance of the Army's role and mission has increased with the development of missiles. It is more powerful and more mobile than ever before in its history. Even with its operational control of missiles limited to those with ranges of 200 miles or less, its zone of operations on a battlefield has been greatly extended over the relatively narrow strips that were its responsibility as forward zones in World War II and Korea.

The *Jupiter* is only one of "between 30 and 50 projects" now under way at Redstone Arsenal and ABMA. These projects are being conducted for and in co-operation with the Army, Navy, Air Force and Marines. Many of them are already programmed for as long as 1962.

Informed estimates on the amount of money still available to Redstone and ABMA from the appropriations of recent years—funds authorized but not expended from as far back as fiscal 1950—are as much as $750 million.

Some of it would have been earmarked for work at other arsenals and by private industry, but the ultimate control would remain with Redstone and ABMA. This is in addition to the funds that Redstone and ABMA will receive for missile and rocket projects from the Army's fiscal 1958 appropriation of about nine billions.

On top of this is the obvious effect on the Army and its contractors of the recent decision to equip NATO allies with missiles. If the established pattern of military aid to Europe is followed, the Army will be asked first to train and equip NATO units with some of the earlier missiles such as the *Corporal*, *Honest John* and *Nike*, plus smaller ones such as the anti-tank *Dart*, a little five-footer.

Anechoic Chamber in World's Largest Sound Laboratory, General Electric Company, Pittsfield, Massachusetts. AN-ECK-OIC® wedges, Radiation Shielding and Spring Tension cable floor fabricated and erected by THE ECKEL CORPORATION, Cambridge, Massachusetts.

. . . at General Electric, Pittsfield, Massachusetts

WORLD'S LARGEST SOUND LABORATORY

Another AN-ECK-OIC® Wedge Installation.

One of the prime purposes of this unique laboratory is to study transformer noises—what causes them and why. This sound laboratory can accommodate transformers rated 500,000 KVA and higher. So completely does it exclude outside noise that it insures the highest possible accuracy in sound-level studies of electrical equipment.

Anechoic Chambers are also recognized as valuable facilities for analyzing noise sources in automotive and aircraft engines, components, auxiliary machines, electric and audio equipment.

In many of the Anechoic Chambers in the United States, AN-ECK-OIC® Wedge units made by—THE ECKEL CORPORATION provide the near-perfect sound absorption.

For the silencing of Engine Test Cells, Firing Ranges, noisy machines and equipment consider the use of ECKOUSTIC® Sound Control Panels.

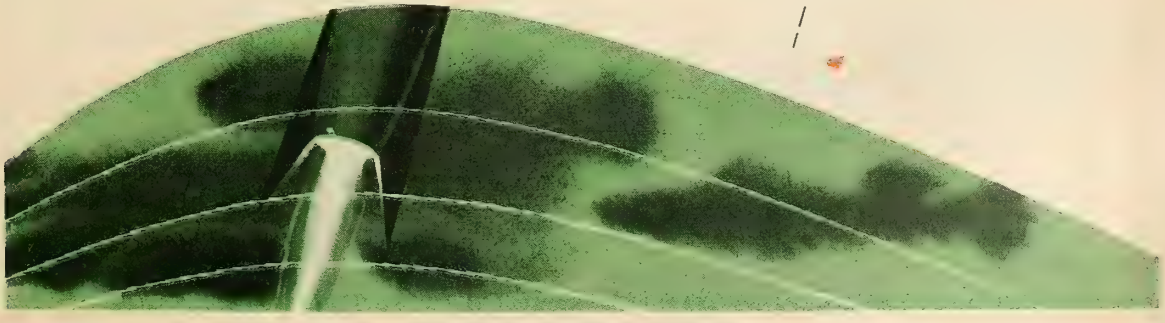
Now! Cool through the thermal barrier with FLAMEMASTIC!

The high-heat insulating *material proved* in *actual production* for *4 years*

Now, you can provide positive protection and high-heat insulation for metal surfaces with FLAMEMASTIC. For four full years, FLAMEMASTIC has been used exclusively on one of the major production missiles. And it has been applied extensively in other experimental firings of rockets and missiles and on allied test and launching equipment.



FLAMEMASTIC protects against high-velocity combustion heats, ranging from 3000° F. upward. This insulation provides positive protection for vital electronic equipment.

FLAMEMASTIC is readily applied by conventional application methods.

"DELIVERY...PDQ*"

From Narmco's shipping department to your manufacturing facility, "Metlbond" structural adhesives and "Conolon" laminating materials are given every packaging and special handling protection. All Narmco products leave our Costa Mesa, California plants under scientifically-controlled conditions insuring Peak Delivered Quality.* This practice is consistent with Narmco's dominating philosophy of complete customer cooperation *from production line to flight line.*

Narmco's insistance on the ultimate in protective packaging, in controlled shipping conditions, and in informative marking and labeling, zeros in on one of the toughest problems faced by missile and airframe manufacturers... delivery of quality structures and assemblies under budget and on schedule! Receiving needed material on time and in top condition is of key importance in keeping production lines operating at profit-making efficiency. Assurance of consistently high quality after shipment is vital in terms of meeting production schedules. That is why Narmco strictly enforces protective packaging and controlled shipping requirements.

Attention to such "important trifles" is another reason for Narmco's leadership in structural adhesives and laminating materials... another reason why more and more Narmco products are being used by an ever greater number of airframe and missile manufacturers... *doing jobs every day that metals alone can't do!*

**Peak Delivered Quality*

Floating Telemetry Bases for AF Test Range

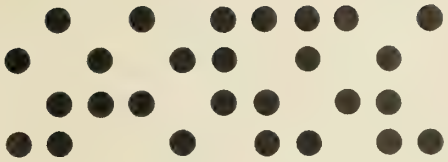
Floating telemetry bases will be used to fill the gap that now exists in the Air Force's missile test range between St. Lucia and Ascension.

Six Liberty ships have been demothballed at Oakland, Calif. and telemetering equipment has been installed by the Ralph M. Parsons Co., Pasadena, Calif. Operation of the fleet will be under direction of the Guided Missiles Range Division, Pan American World Airways. Operation will begin later this year.

Electronic equipment on board will be operated by the Radio Corporation of America, subcontractor to Pan American. A special area in the ships is designed to provide controlled ambient atmospheric conditions to insure accuracy of recorded data acquired by helical telemetry antennas mounted on the bridge of each ship. Data will be transmitted from the ships to Cape Canaveral, Fla. where the AF range control station is located.

The ships will be capable of operation for three week periods before returning to their bases in South America. The work of the "ocean range vessels," as they are called, will be supplemented in 1958 by five larger vessels that will be used to record missile impact data.

Temco Predicts Sales of $127 Million



Temco Aircraft Corp.'s president Robert McCullough has predicted that his company will do $127 million in business this year, compared to $90 million in 1956.

He said that the company's Garland plant will have 3,000 employees by early 1958. Its payroll will reach $7.5 million this year, compared to a little over $6 million last year. McCullough hinted that Temco's operation in Grand Prairie eventually may be moved to Garland where the company is building a $2 million engineering and office building on its 400-acre site.

The Garland plant is working on the Navy *Corvus* missile.

A. C. Sparkplug Gets Missile Facility Funds

A. C. Sparkplug Division of General Motors has received a $3,340,000 contract from Air Materiel Command for ballistic missile facilities. The company is working on guidance for *Thor* IRBM.

COMPUTERS

If you are an experienced computing analyst—or if computing and data reduction are new to you but you are a qualified engineer—there is interesting work as well as a bright future for you in Northrop Aircraft's growing Computer Center at Hawthorne, California.

Applied mathematicians and engineers are needed as computing analysts for assignment to Northrop's analogue computing facility, as well as the newly expanded digital electronic computer department which provides unparalleled service in the practical solution of complex engineering problems.

Northrop has many openings on its other projects having to do with jet aircraft and missile design. They include positions for electronics and electro-mechanical engineers and lab technicians. In addition to attractive compensation, Northrop offers benefits unexcelled in the airframe industry as well as helpful cooperation by forefront engineers for your professional advancement.

You'll like the comfortable working conditions, friendly people and modern equipment at Northrop. And you and your family will be living in Southern California where sea, mountains and desert offer year 'round recreation.

If you qualify for any phase of computer research, design or application, we invite you to contact the Manager of Engineering Industrial Relations, Northrop Aircraft, Inc., ORegon 8-9111, Extension 1893, or write to: 1015 East Broadway, Department 4600- L, Hawthorne, California.

New Way to Make Titanium Tetrachloride

Scientists at Armour Research Foundation of Illinois Institute of Technology have developed a way to make titanium tetrachloride at temperatures much lower than required for the present method—with a higher purity and at less cost.

The compound is necessary in the manufacture of titanium.

The new process opens the way for use of low grade ores, such as ilmenite, in titanium manufacture, according to Clark E. Thorp, manager of the Foundation's chemistry and chemical engineering department.

The process starts with a "cold chlorination" of ilmenite ore at freezing temperatures, where the conventional process requires very high temperatures to chlorinate a high grade ore (rutile).

Key reaction is the precipitation of potassium chlorotitanate from ilmenite solution and the decomposition of the precipitate into titanium tetrachloride and potassium chloride at candle flame temperatures.

Thorp said it will take some time to develop the process fully. Patents have been applied for, and the Foundation is offering the process to industrial sponsors for further development.

Aerojet-General Has Private Stock Sale

Private placement of 33,500 shares at $225 per share of common stock of Aerojet-General Corp. and promise of a 10-to-1 split before year's end has been announced by William O'Neil, president of General Tire & Rubber Co., chief stockholder.

The sale was negotiated by Kidder, Peabody & Co., Inc., and Auchincloss, Parker and Redpath, and leaves General Tire's ownership at 87.6%. Proceeds will be added to working capital.

O'Neil said the placement agreement included assurance that General Tire would not consent to conversion of outstanding Aerojet-General preferred into common stock and that General Tire would vote for a split in Aerojet-General's common on at least a 10-1 basis within a year.

Aerojet Gets Contract for Engines, JATO's

Aerojet-General has received a $1,948,924 contract for 1.8KS-7800 rocket engines and $723,232 for JATO's and igniters, according to the Department of Commerce.

"ECLIPSE" a recent painting by Simpson-Middleman, gifted artistic interpreters of the physical sciences. About this new expression they write: "'Eclipse' was painted as a result of watching an actual eclipse of the sun. We were particularly struck with the curious light that was both dim and glowing and the unusual pattern of the shadows on the leaves of the trees around us. We had never seen anything like it before." Painting courtesy of John Heller Gallery, Inc.

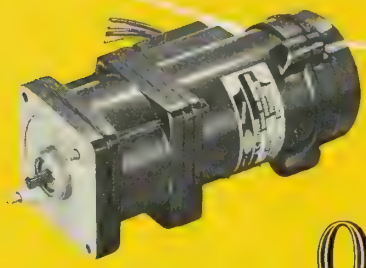
There's engineering excitement at Boeing

If you enjoy working on exciting, limitless-future projects, you belong at Boeing. For here you can explore problems involving the development of inertial and electronic guidance systems, chemical fuel propulsion, new metals, new processes. You can gain in professional stature on such Boeing projects as the 707, America's *first* jet transport, the B-52 global jet bomber, and an entire weapons system spearheaded by the supersonic Boeing Bomarc IM-99, an advanced missile of far greater range than any other now in use in air defense.

Boeing needs engineers of ALL categories, and physicists and mathematicians, for long-range assignments in design, research, production or service. You'll find the excitement of the future at Boeing—today.

Drop a note now to: John C. Sanders, Engineering Personnel Administrator, Boeing Airplane Company, Department R-65, Seattle 24, Washington.

BOEING



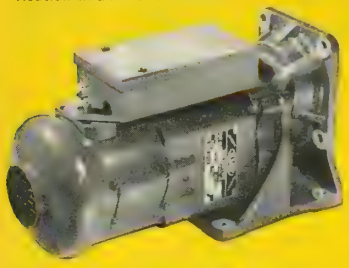
Because in missiles and jet

aircraft everything has to work the first time

EEMCO AC and DC Motors

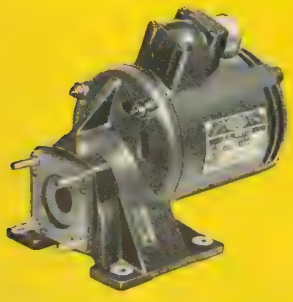
have been chosen for use in the majority

of our latest aerial weapons.

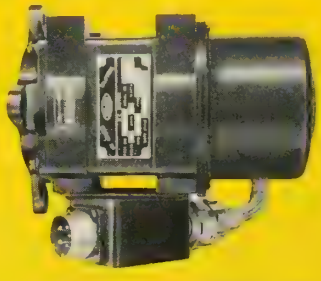


Type: C-1874 400 cycle 3 phase AC Motor and Clutch. **Weight:** 4.5 lbs. **Voltage:** 200 volts. **Output:** 650 watts. **Intermittent duty:** 12,000 rpm. **Meets Military Specification** MIL-M-7969A (ASG).

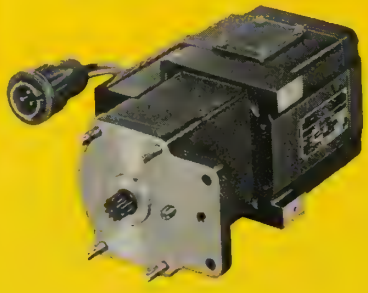
Type: D-638 400 cycle AC Motor. **Weight:** 17.5 lbs. **Voltage:** 200 AC, 20 amps at 6.5 hp. **Duty cycle:** 3.0 seconds at 6.5 hp, 15.0 seconds at 1.5 hp. **Maximum capacity:** 6.5 hp. **Continuous rating:** 5 hp at 2300 rpm, 15.8 amps, 200 volts. **Meets Military Spec.** MIL-M-7969A (ASG).



Over the years the precision, ruggedness and reliability of EEMCO products has been proven time and time again. The consistent, exceptional performance of these low-weight, high-output motors, a few of which are illustrated, has earned EEMCO industry-wide recognition. In this highly specialized field, where perfection is imperative, the widespread use of EEMCO motors and of EEMCO's equally reliable actuators is eloquent testimony.



Type: D-751 DC Motor. **Weight:** 20 lbs. **Duty Cycle:** 5.2 hp at 2100 rpm (intermittent) on 26 volts DC; 3.5 hp at 2200 rpm (continuous) on 26 volts DC. **Meets Military Specification** MIL-M-8609.



Type: D-800 400 cycle 3 phase AC Motor. **Weight:** 8.75 lbs. **Voltage:** 208 volts. **Horsepower:** 2.5 hp. **Continuous Duty:** 11,300 rpm; Equipped with thermal protector. **Meets Military Specification** MIL-M-7969A (ASG).

Type: D-899 400 cycle 3 phase AC Motor. **Weight:** 11.25 lbs. **Volts:** 200 volts. **Load:** 2.75 hp continuous output. **RPM:** 3140 rpm output at gear box. **Power factor:** 83%. **Overall efficiency:** 76% for entire unit. **Meets Military Specification** MIL-M-7969A (ASG).

Type: D-932 DC Motor. **Weight:** With radio noise filter—13 lbs., without same—12.4 lbs. **Terminal voltage:** 27.5 DC plus or minus 1.5 volts. **Load:** From .5 hp minimum to 2.6 hp maximum. **Speed:** Continuous at 12,000 rpm, plus or minus .005%. **Speed Control:** By frequency regulator supplying control field. **Meets Military Specification** MIL-M-8609 (ASG).

Type: D-927 DC Motor. **Weight:** 7.25 lbs. with 2-circuit noise filter for ungrounded systems. **Weight of filter:** 1 lb. **Terminal voltage:** 27 volts, 18 amps. **Load:** 0.5 hp. **Speed:** Continuous at 9900 rpm. **Meets Military Specification** MIL-8609.

INTERNATIONAL NEWS

By Anthony Vandyk

Bloodhound is Mainstay of British Air Defense

New details have been released about the Bristol/Ferranti *Bloodhound* surface-to-air missile system. *Bloodhound* will be the mainstay of the automatic system which will progressively take over the defense of the UK from the manned fighters.

Bloodhound is a semi-active homing missile (guided by a radar beam projected at the target, and reflected back to receiving equipment in the missile itself). As a hostile aircraft approaches, its position is plotted and followed by radars. Coordinates of this position are fed automatically to a second ground radar unit and the missile launchers move automatically to bear on the target. As soon as the echo from the target indicates by its strength that the target is within range, a green light flashes in front of the launch controller who has only to press the firing button to send *Bloodhound* roaring into the sky. From that moment the hostile aircraft has failed in its mission—no amount of evasive action by the target can shake *Bloodhound* off the scent, Bristol states.

Reflections of the illuminating radar beam from the target are received by *Bloodhound*. In this way, the target illuminating beam enables the missile to "see" the target in much the same way as a searchlight would enable it to be seen by the eye. During flight, the missile senses the direction from which the illuminating beam is being reflected and automatically turns towards the position of the target. Any evasive action the target may make is automatically followed and appropriate signals from the guidance received to the missile control surfaces continuously correct the heading of *Bloodhound* relative to the target.

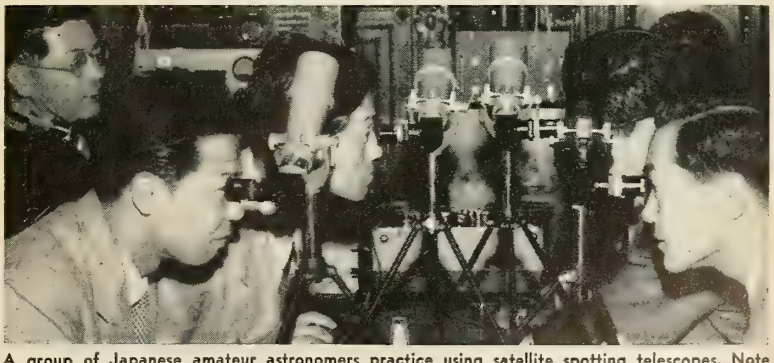
The *Seaslug*, the first guided surface-to-air missile for the Royal Navy, is a medium-range weapon, it has been officially announced in England. It is a rocket-propellant missile, with rectangular cruciform wings and tail guidance blades, launched by four wrap-around solid propellant boosters mounted on the forebody. Triple launching ramps, with automatic loading from magazines below decks, are used so that personnel are not exposed.

Targets are initially detected and tracked by long-range radar. Feed-in of target range, bearing, height and speed information is computed to position launching ramp and indicate firing time. The system is fully compensated for ship's roll. The missile apparently has fully active homing.

Firings of the *Seaslug* have taken place at Woomera, Australia and at Aberporth, Wales, from the Clausen rolling platform which simulates a ship's motion. Since July 1956 sea firing programs have been undertaken in HMS Girdle Ness, the Royal Navy's first all-missile ship.

While the missile designed was coordinated by Sir W. G. Armstrong Whitworth Aircraft, the launching ramp, magazine gear, radar and associated weapon direction and control equipment were developed by the Navy. Contractors "intimately connected" with the weapon system were: the General Electric Co. Ltd. (guidance), Sperry Gyroscope Co. Ltd. (autopilot), John Thompson Conveyor Co. Ltd., Sir George Godfrey and Partners, Vickers-Armstrongs Ltd., Metropolitan Vickers Ltd., McMichael Radio Ltd., E.M.I. Engineering Development Ltd., and Imperial Chemical Industries.

Japan Shows Interest in Satellite Tracking



Japan seems more enthusiastic and excited by the forthcoming satellite launchings than any other nation, not excluding the U.S.

Japanese interest in rockets and astronautics was described in this magazine earlier (October and November, 1956). But the desire to participate in the U.S. satellite tracking program is greater than that shown by any other nations within the 40° North and South parallels. The extent of this popular interest is shown by the number of volunteer satellite observing teams.

Dr. Masai Miyadji, Director of the University of Tokyo Observatory, was picked by the Japanese National Committee, IGY, as coordinator for satellite tracking. This action was taken last October by the Japanese Science Council following the CSAGI meeting at Barcelona. Miyadji, an astronomer, is currently completing a six-week visit to the Smithsonian Astrophysical Observatory at Cambridge, Mass., center of optical tracking programs.

Dr. Miyadji's particular specialty is "time and space." While in the U.S. he will study optical and radio tracking.

A modified Schmidt camera, crys-

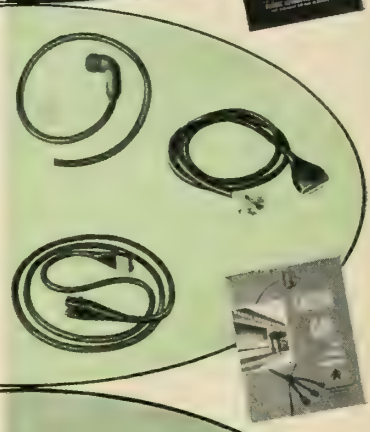
A group of Japanese amateur astronomers practice using satellite spotting telescopes. Note individual time signal keys, radio time signal receiver, and tape recorder. In background, not shown, is projection screen for use in simulating satellite motion of 1/5 to 1 degree per second. Students are members of Japanese Astronomical Study Association and are training for Japanese Moonwatch program. Photo was taken at the Science Museum in Tokyo.

Engineering representatives will be happy to discuss your design problems when you visit them at Booth 159, Air Power Panorama, Washington, D. C. July 31-Aug. 3; Booth 2412, WESCON Show, San Francisco, August 20-24.

4 NEW design aids providing working data for every ELECTRONIC CABLE Problem

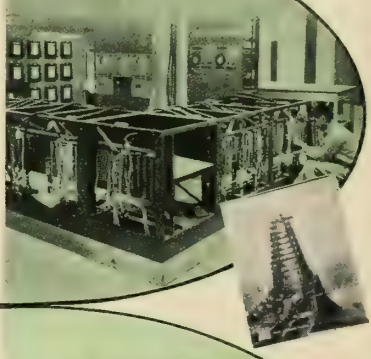
...available from Pacific Automation Products, a company established to provide a product as well as a service, which utilizes a 50,000 sq. ft. factory and an experienced staff of qualifed engineers and technicians to design, manufacture and install custom made neoprene jacketed cable for the vast electronic industry.

Engineers and technicians are invited to investigate career opportunities with us. Submit resume for interview.



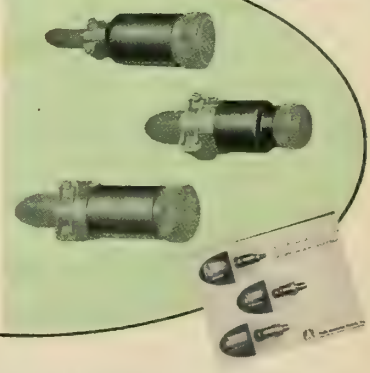
CABLE SPECIFICATIONS

"Design Engineering Specification" Bulletin No. PAP-C-101. Comprehensive 19-page engineering manual describing materials, construction, design criteria, specification conformance, performance, identification, documentation and other important features determining correct cable for your specific application.



CABLE AS A COMPONENT

"Electronic Cable as a Systems Component" Bulletin No. 656. Generously illustrated pamphlet describes design and production of electronic cable in bulk and assemblies. Connectors and hardware; cable break-outs; environmental requirements; voltage rating, testing; cable procurement data – are some of the subjects covered in this bulletin.



CABLE SYSTEMS

"Engineered Cable Systems" Bulletin 357. Illustrated brochure describing Pacific Automation Products' pioneering in the use of the Systems Concept to coordinate cable design with the development of complex electronic systems. Liaison engineering teams cooperating with systems design groups establish cable as integral part of system, supervising cable construction concurrently with development of other elements.

CABLE ACCESSORIES

"Extension and Adapter Sleeves for Cable/Connector Compatibility" Bulletin 257. Illustrated bulletin on aluminum adapters designed and manufactured by Pacific Automation Products, which for the first time provide a means of attaching any size AN connector to any size cable, with assured reliability.

tal clock timer and associated equipment will be provided by the U.S., and installed at the Tokyo Observatory by January 1958. The station will be one of the 12 official U.S. stations. The Japanese Science Council and Tokyo University will cooperate in station management and operation.

In addition volunteer observing teams are being readied under the Moonwatch program. Twenty-five of these teams have already been officially approved and 5-10 more are in the process of organization. Dr. Miyadji is assisted by a committee of three: Professor Hirose, Mr. Torao, and Mr. Iijima, all of the Tokyo Observatory.

It was learned that the three major astronomical and two rocket societies have pledged support: Japanese Astronomical Society (Tokyo), Oriental Astronomical Society (Kyoto), Japan Astronomical Study Association (Yokahama), Japanese Astronautical Society (Tokyo) and the Japanese Rocket Society (Tokyo).

Total membership of these societies is about 3000.

Science departments of high schools are organizing observing teams under the leadership of Mitsuo Harada, science writer and president of the Japanese Astronautical Society. Whether or not these teams receive accreditation as official observers, they will be encouraged by the Science Council because of the scientific interest and training of students which will result. Each team is headed by a responsible accredited astronomer.

Three major newspaper chains, Yomiuri Press, Asahi Press and Mainichi Press, have agreed to pick up the tab for spotting equipment needs. A Japanese optical firm has designed high-quality monocular 'scopes at a cost of about $40 each.

Sweden to Employ Anti-Tank Missile

Sweden's Guided Weapons Bureau now has a staff of about 250, General C. A. Ehrensvard, Commanding General of the Swedish Army, has disclosed. Discussing details of the Army's guided weapons procurement program, he said that nuclear weapons supplement other weapons but do not replace them. The first missile to be introduced on a large scale among the Swedish defense forces will be an anti-tank missile.

This is likely to be the French wire-guided *Nord* missile in its improved SS-11 version. If tests with the missile are successful the Army will acquire the *Nord* SS-11 in sufficent quantities for its war organization.

World Astronautics

By Frederick C. Durant III

Arrangements may now be made for attendance at the Eighth Annual Congress of the International Astronautical Federation (IAF). The meetings will be held at Barcelona, Spain, October 7-12. The Spanish host society is the Agrupacion Astronautica Espanola.

The Thomas Cook & Sons tourist agency has been designated as official agent for hotel reservations for the congress. Block bookings in all classes of Barcelona hotels have been made. Check with the nearest office of Thomas Cook & Sons which has branches in all major U.S. cities, or with the Barcelona office, address:

Wagon Lits Cook, Paseo de Garcia, 8-10, Barcelona, Spain.

All meetings will be held at The National Center for Scientific Research, Barcelona, with one exception; the initial meeting of the IAF Council on Sunday, 6 October.

•

A. V. Cleaver, British rocket expert of Rolls Royce, Ltd., has authored an interesting two-part article in "Flight" recently. Cleaver, a past chairman of The British Interplanetary Society, compares the predictions of early aircraft builders and scientists (circa 1900-1930) concerning future developments in aviation. They underestimated by a wide margin the rate of advance and extent of future aeronautical progress.

Cleaver draws an interesting parallel between the progress in rocket technology of today and realization of space flight tomorrow. One error made by the pundits of a few decades ago was in not recognizing the cumulative effect of many individual technical improvements upon future aircraft performance. It is possible that the same error in synergism may be made in today's predictions of the rate of achieveing manned space flight. Furthermore, the exponential rate of technological growth of the past decades may be expected to produce breakthroughs of completely new techniques and developments that are today unidentified. The import: astronautical developments possibly much sooner and on a greater scale than now anticipated.

•

A symposium on "High Altitude and Satellite Rockets" to be held 18-20 July at Cranfield, England, is being organized jointly by The British Interplanetary Society, Royal Aeronautical Society and the College of Aeronautics. This top-level meeting and exhibition is the first such affair to be held in Great Britain. The program resembles the pattern of the week-long course, in "Orbital Vehicles and Satellite Flight" held at MIT last summer.

•

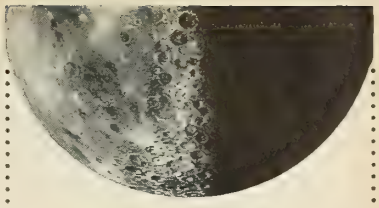
Nearly 200,000 visitors were attracted to the U.S. rocket exhibition in Frankfurt recently. A similarly large attendance occurred at Stuttgart. Entitled "Space Unlimited" these shows stress the peaceful application of rocket power. Much good will has resulted. A film, titled "Adventure in Space Flight" has been produced by the U.S. Information Service. It features unclassified films of *Aerobee, Viking, Nike* and American V-2 research. There is strong interest in more of the same. The USSR Embassy at Bonn is countering with releases of information on Russian space medical research using dogs in sounding rocket flights.

Behind the Curtain

By Dr. Albert Parry

Soviet scientists plan to use rockets in their ambitious scheme to radically change the night lighting of Soviet cities. Clouds of luminous gas in the ionosphere are to be utilized for such lighting. The procedure will be as follows: As twilight falls, rockets will be employed to throw into the ionosphere a catalytic agent which will cause atoms of oxygen to form into molecules. It will be in the process of this formation that the needed light will be produced for Soviet streets.

Russian savants are not saying, however, just how soon this revolutionary change in their municipal mode of life will be brought about.



To the question, "When will the Soviets send up their first earth satellite?", Moscow replies rather vaguely: "In the next few months." But a much more exact date is the educated guess of an émigré Russian now living in the U.S. He is V. Nekrasov, an elderly artillery expert sent to this country by the tsarist government during World War I as a staff member of the tsar's commission to buy munitions for the Russian army. Interested in rocket propulsion since his young manhood, and well acquainted with the life and work of Constantin Tsiolkovsky, Russia's pioneer rocket theoretician and inventor, Nekrasov now says:

"September 17, 1957 will mark the one hundredth anniversary of Tsiolkovsky's birth. Quite some time ago the Soviet government announced that it would celebrate the date in a most fitting manner. But since that announcement not a further word has been said by Moscow's officials about the celebration. We can explain this silence by one reason only: the Soviet government is preparing to spring a surprise on the world—it will celebrate the Tsiolkovsky Centennial by firing the Soviets' artificial satellite into space on September 17 of this year."

Through its Czechoslovak Press Agency, the Prague government indignantly denies the recent reports appearing in West European newspapers, particularly those in Austria and West Germany, that the Soviet armed forces have established guided-missile launching sites on Czechoslovak territory. Declares the Czechoslovak government:

"No such bases exist in Czechoslovakia. It is obvious that the circulation of such false reports is a transparent propaganda maneuver intended to divert the attention of the public from the fact that the U.S. has for some time been equipping its military bases in the German Federal Republic with atomic weapons with the approval of the West German Government, and at the present time the Government of the German Federal Republic is rapidly moving towards the equipment of its forces with atomic weapons. Inventions of this type cannot, however, either hide the actual preparations for atomic war on the territory of West Germany or disperse the fears of the German people of the catastrophic results of such a policy, which were so emphatically expressed recently by leading West German atomic scientists."

The Red verbiage aside, this official Prague statement shows clearly that the Czech Communists and their Soviet Russian bosses are sufficiently worried by the reports of their East European guided-missile launching sites to take this trouble of denying the reports.

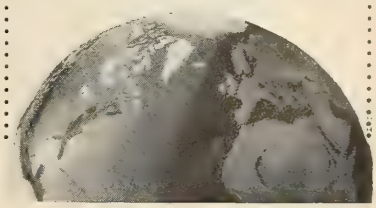
SENIOR RESEARCH ENGINEERS

(BS and 2 years' rocket engine experience)

to join a small but heavyweight group doing some of the most stimulating work in rocket engineering.

If you are an experienced rocket engineer, well grounded in the realities of design, development, and application of advanced propulsion systems, there is a special opportunity for you in our Preliminary Analysis Group right now.

The men you'll be with are our applications men—qualified experts, with many specialties and a broad outlook. They think imaginatively, continually coming up with new answers to the question "What new rocket engine systems are needed to propel tomorrow's hypersonic missiles and aircraft?" They conceive, they evaluate, they formulate. Their function is to be a task force with an over-all grasp of the big picture—the unique potentialities of the large rocket engine in highly advanced weapon systems technology.



As a Senior Research Engineer with this group, you'll contact customers, working with them on their requirements, guiding them on applications. You will plan the approaches and organize the means to solve problems inherent in the over-all development of highly advanced propulsion systems. You'll be gaining experience in such fields as new and improved propellents . . . relative merits of different systems . . . selection of over-all engine systems, parameters and principal components. *You* can help point the way to the development of the world's most powerful engines.

Write and tell us about your background: Mr. A. W. Jamieson, Engineering Personnel Dept. MAR-7, 6633 Canoga Avenue, Canoga Park, California.

Photonic Propulsion Discussed By Reds

In *Komsomolskaya Pravda* for June 9, Moscow's Professor K. P. Stanyukovich discusses the "photonic rocket, the mightiest theoretically possible jet motor." He writes:

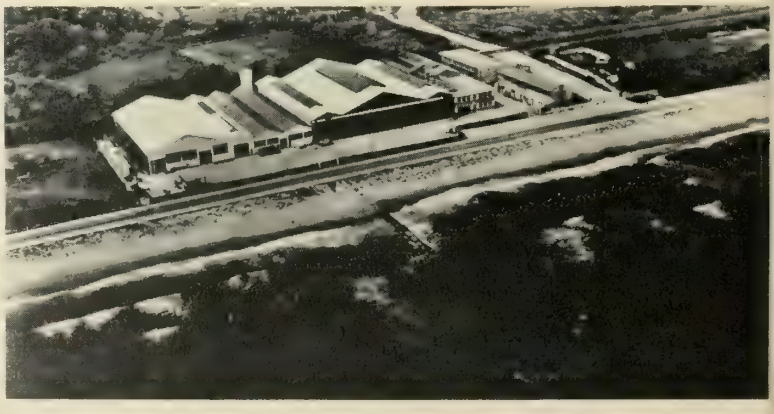
"You know that in most recent years scientists have discovered the existence of so-called anti-particles, that is to say 'matters in reverse.' They have succeeded in creating some of these artificially.

"Right after being 'born,' having existed but a most insignificant portion of a second, they immediately vanish. They vanish when they run into a particle analogous to themselves. But a tremendous amount of energy comes out of this, hundreds of times more than even at a hydrogen-helium nuclear reaction.

"It is quite possible to imagine that this emergence of energy would come not as an explosion but as a relatively stable process.

"It is probable that, as a basis of an interplanetary ship, man will then use one of the satellites of either Saturn or Jupiter, or perhaps some or other large asteroid. Man will bring to it the needed quantity of anti-matters, will install there a gigantic motor, and one beautiful day this celestial body will leave its age-old path in the solar system and will hurl itself into the black abyss of the Universe.

"Of course, both the 'combustion chambers' and the 'jet' of this motor will not at all resemble what we know today of motors. Most likely these will be annular magnetic fields which will organize streams of matter and of photons. The jet stream, or more exactly the jet ray of the interplanetary ship, will be of such intensity that even at a distance of millions of kilometers it will burn everything living—in case this ray falls upon the earth. Precisely for this reason, man will place the cosmodrome for this interplanetary flight so far away from the earth.



"Should it 'burn' in its motor 90 per cent of its mass, or the first stage of the rocket, so to say, our ship will fly from 250 to 280 thousand kilometers per second. Therefore, most likely, man on the earth will lose all touch with this interplanetary reconnoiterer.

"Some 10 or 15 years will pass, and then, in the black abysses of Cosmos, a star will emerge, coming toward us with a fantastic speed. It will shine forth with its ray of energetics, facing the solar system, as if it were the ray of a searchlight. The first navigators of stars will thus turn their photonic motor on, in order to brake their flight.

Professor Stanyukovich concludes by admitting that even the twenty-first century may not see this dream come true. But he insists that scientifically all this is quite plausible.

RCAF Orders *Firebees* For Training Troops

Ryan Aeronautical Co.'s *Firebee* jet target drone will be used by the Royal Canadian Air Force for anti-aircraft training of its defense forces. Canada ordered a number of the drones following a 10-day conference recently with Ryan officials.

What a wonderful location for a missile plant! This is Sud-Aviation's missile factory at La Bocca, on the shores of the blue Mediterranean near Cannes. The plant occupies an area of 15,600 sq. yds. and has a labor force of 380. Equipment includes 160 machine tools. Main activity of the French facility is the design and construction of missiles up to the pre-production stage.

Rocket Trends

by Erik Bergaust

AIR FORCE MISSILE MEN have discovered the solid propellant trend. Reportedly the Ramo-Wooldridge organization has presented a comprehensive report on solids to ARDC's Ballistic Missile Division. Some sources say the report indicates feasibility of solid-propellant ICBMs and that Gen. Ben Schriever is interested . . . Aerojet and Thiokol representatives have hinted it is possible to build a solid-propellant moon rocket. "If we can build a solid moon rocket, we can also build a solid ICBM," one industry spokesman said.

AIR FORCE AND CONVAIR were pleased with the first *Atlas* firing. The *Atlas* design concept proved to be sound. In particular, Convair *Atlas* designers were satisfied their thin-skinned pressurized hull proved satisfactory. First firing was perfect from first moment of ground check-out and countdown. Missile took off beautifully and a maze of information was telemetered back to Patrick. Fuel feed malfunction is considered minor problem, and stepped-up *Atlas* test program is underway.

AIR MATERIEL COMMAND's Maj. Gen. Baker sees a 500% increase in the next few years in missile spending; a 100% increase in military electronics and a 50% decline for manned aircraft; 40% down for turbojet engines. AF military hardware spending to hold at $7 billion with a $600 million per year R&D account. Missiles are to go from $500 million per year to $2.8 billion; aircraft to drop from $4 billion now to less than $2 billion. Electronics up from $750 million to $1.3 billion plus . . . "Money will be flowing to industry through a much more limited number of channels . . . neither R&D nor procurement can continue to support losers . . ."

AIR FORCE OFFICE OF SCIENTIFIC RESEARCH reports of high velocity and high temperature effects being investigated in a "variety of ways" under auspices of AFOSR's Physics Directorate. AFOSR's "Research Briefs" mentions some of the methods developed under AFOSR sponsorship, for example, light gas guns and electromagetic accelerators which drive pellets of 1 to 5 grams at velocities up to 33,000 feet per second. This work is being done at the University of Utah. Electronic accelerators being developed at Armour Research Foundation and at Utah should deliver even more reproducible results. These institutions are attempting to attain velocities approximating the cratering effects of meteoric dust particles hitting against metallic surfaces used for missiles and satellites, with velocities from 25,000 to 100,000 feet per second expected.

AIR FORCE AND ARMY MISSILE FEUD should possibly be considered in light of the fact that in Russia all medium-range and long-range missiles are under jurisdiction of the Red Army. Recently, several Soviet generals and marshals artillery have been permitted publicly to state that (in Col. Gen. Fomin's words in November, 1956) "long-range rocket weapons of intermediate and strategic types . . . constitute a form of artillery. Now artillery can be employed . . . also far beyond the limits of the tactical zone of operations of the ground forces." Col. Gen. Samsonov similarly spoke of long-range rockets as "a variant of rocket-firing guns. Thus we witness a new qualitative leap in the development of artillery."

LADIES ARE NOT PERMITTED to wear shorts in the Officers Club at Patrick AFB! Military personnel may wear civilian clothing off-duty at AFMTC installations, and although the Air Force admits "informality is the keynote to civilian clothing worn in Central Florida," ladies can't wear shorts in public places such as base exchange, commissary, bank, etc. "Base regulations should be consulted on civilian attire permitted for men and women at the Officers Club and other public places on the base," AF advices.

ENGINEERS...

MAC presently has stimulating engineering positions available in a great variety of fields including:

•

Internal Aerodynamics
Design Engineering
Structures Engineering
Electronic Component Engineering
Aerodynamics
Structural Dynamics
Electronic Packaging Engineering
Operations Engineering
Electronic Circuit Analysis
Dynamics
Airloads and Flight Criteria
Aircraft Fire Control Systems
Aeroelasticity and Flutter
Thermodynamics
Wind Tunnel Test Engineering
Flight Test Engineering
Reliability Engineering
Telemetry Systems Engineering

Washington Spotlight

By Henry T. Simmons

The U.S. will come under increasing pressure from its NATO allies during the next few years for shipments of guided missiles in addition to manned aircraft. A top Greek Air Force general told visiting U.S. newsmen in Athens last month: "Within the next five years, we must have some surface-to-surface and surface-to-air missiles. Without these new weapons we will not have the proper power to carry out our missions."

•

So far, only England has officially requested U.S. missile assistance. Other NATO nations like Greece and Turkey apparently lack fundamental information on important categories of missiles, particularly air-to-air. Neither the Greeks nor the Turks have conducted a formal study of their own missile requirements, and it is doubtful whether they can take even this first step without substantial American help.

•

Practice firings of the *Matador* surface-to-surface missile at the Air Force's 200-mile missile range in the Libyan Desert are a big event for several nomadic tribes of Arabs in the area. They are alerted when the weapons land, there is an immediate race by the tribesmen to capture the junk and sell it as scrap. For some years after World War II the export of shattered tanks and other equipment was a major industry for the Libyans.

•

The Army is pondering the possible joint use of the USAF missile range in Libya for training exercises of its own units stationed in Europe. The Army now has *Honest John* and *Corporal* surface-to-surface weapons in the European theater and could profitably use the African firing range established by the Air Force. Its need for a long range will be particularly acute when *Redstone* units are assigned to Europe.

•

The Air Force has revealed some surprising personnel figures for its first guided missile wing, the *Matador*-equipped 701st Tactical Missile Wing stationed in Europe. The wing has a grand total of 2,881 officers and men who operate or support 18 *Matador* missile launchers. This is almost the number of men required by a wing of strategic bombers; it suggests that the age of push-button warfare may not be as economical in manpower as initially presumed.

•

Missile strength of the U.S. Navy's Sixth Fleet in the Mediterranean was at a low ebb in June, but will increase substantially when new fleet units arrive this month. Only missile deployed in the Fleet last month was the infra-red *Sidewinder* air-to-air missile, carried by McDonnell F3H-2N and North American FJ3-M fighters. This month the Fleet expects the carriers *Randolph* and *Franklin D. Roosevelt,* which should have all-weather F3H-2N *Demons* equipped with *Sparrow III* missiles. *Randolph* may also have a *Regulus* surface-to-surface missile capability. In addition, *Terrier* anti-aircraft missiles will return to the "Med" this month with the arrival of the cruiser *Canberra.*

•

The Army will begin to ship *Nike Ajax* guided missiles to its units in Europe before the end of the year. First unit to get the weapons will be the 32nd Anti-Aircraft Artillery Brigade, transferred from England last month to positions west of the Rhine. The 32nd is now equipped with 75 mm Skysweeper and 90 mm cannons, but will be re-equipped with the *Nikes* for defense of the vast Army supply depots in the Kaiserslautern area. Later the 32nd will get the improved *Nike Hercules,* and its defense responsibility will be extended to include USAF airdromes in Europe and other key targets.

Don Walter, B.S. M.S., achieved an outstanding academic record at Cal Tech, Class of '40, while earning seven varsity letters. Today as Vice President in charge of Engineering and Van Nuys Operations, Don utilizes his technical and teamwork background to lead Marquardt's engineering and development manufacturing. He is an example and exponent of Marquardt's management philosophy.

ENGINEERING MANAGEMENT = OPPORTUNITY AT MARQUARDT

Every day, professional engineers are finding *outstanding* career development opportunities at Marquardt Aircraft. Because, at Marquardt, there is no ENGINEER/BARRIER.

Marquardt is guided by a management team with an *engineering* philosophy.

This management team is familiar with, understands and respects the contributions of engineers.

This engineering philosophy eliminates all traces of the ENGINEER/BARRIER—that invisible management level beyond which engineers cannot advance.

Professional engineers interested in joining a company which offers this management team and this engineering management philosophy are invited to write *that* letter to Jim Dale, Professional Personnel, 16555 Saticoy Street, Van Nuys, California.

AiResearch MISSILE AUXILIARY POWER UNIT

Compact, reliable system features high output with simplicity of design

SPECIFICATIONS:

Output: 650 watts, 5000 cycles, 115 volts, single phase
35 watts, 400 cycles, 115 volts, single phase
0.6 gal. per min. at 2000 psi hydraulic pressure

Regulation: ± 5% voltage and frequency

Duration:	27 seconds
Weight:	9.5 pounds
Size:	6.14 in. diam., 6.74 in. long

Ground power: compressed air

This AiResearch auxiliary power package operates the vital electrical and hydraulic systems in a missile.

Gases from a solid propellant spin the unit's turbine wheel at 50,000 rpm. The turbine's shaft drives the following: a 650 watt generator which supplies electrical power to run the missile's guidance system; a 35 watt generator which runs the missile's gyros; a hydraulic pump which in turn powers the servos that control the movable flight surfaces of the missile's airframe.

The hydraulic system features drilled passages which eliminate the need for potentially troublesome plumbing. It includes reservoir, filters, temperature compensator, relief valve, check valve, and squib valve within a single housing.

This auxiliary power system is an example of AiResearch capability in the missile field. Inquiries are invited regarding missile components and sub-systems relating to air data, heat transfer, electro-mechanical, auxiliary power, valves, controls and instruments.

Outstanding opportunities for qualified engineers

MAGAZINE OF WORLD ASTRONAUTICS

Men for Missile Engineering

By J. B. Beerer

Missile Development Div., North American Aviation, Inc.

WHENEVER A NEW scientific or engineering breakthrough occurs there invariably follows a demand for new ingenuity and resourcefulness on the part of man. Thus, in the missile business today we find ourselves looking for new kinds of engineers, technicians and scientists—many of whom don't yet exist in full measure—to solve new kinds of problems.

This demand has been with us for quite some time now, particularly in the intercontinental missile field. No one will predict relief in the foreseeable future. Instead, as the state of missile art grows, so does our need for men of broader knowledge and abilities.

One program which has contributed greatly to the overall state of missile progress in this country is the advanced intercontinental missile, the SM-64 *Navaho*. Since its research inception more than 10 years ago, the *Navaho* project has brought forward major developments in basic missile systems.

The long-term development of large, liquid propellant rocket engines under *Navaho* enables a crash development to be initiated in recent years on the engines for the complimentary intercontinental ballistic missile. However, before any of these supersonic missiles are operational—developed to the point of military usefulness and operable by the military—a substantial amount of engineering and flight test remains ahead.

The *Navaho* is this country's only supersonic air-breathing guided missile project. It differs technically from the ballistic missiles in that it involves the solution of problems peculiar to airborne vehicles—an extension of the problems which the aircraft industry has been traditionally pursuing. The ballistic missiles present a unique set of developmental problems which become very severe at the extreme velocities required for long range.

The *Navaho* program was the first major USAF program established under the management system concept where the development of the complete weapons system — including power plants, guidance and composite design was to be achieved by a single company—North American. This management responsibility extends up to complete operational capability, including personnel training and logistics.

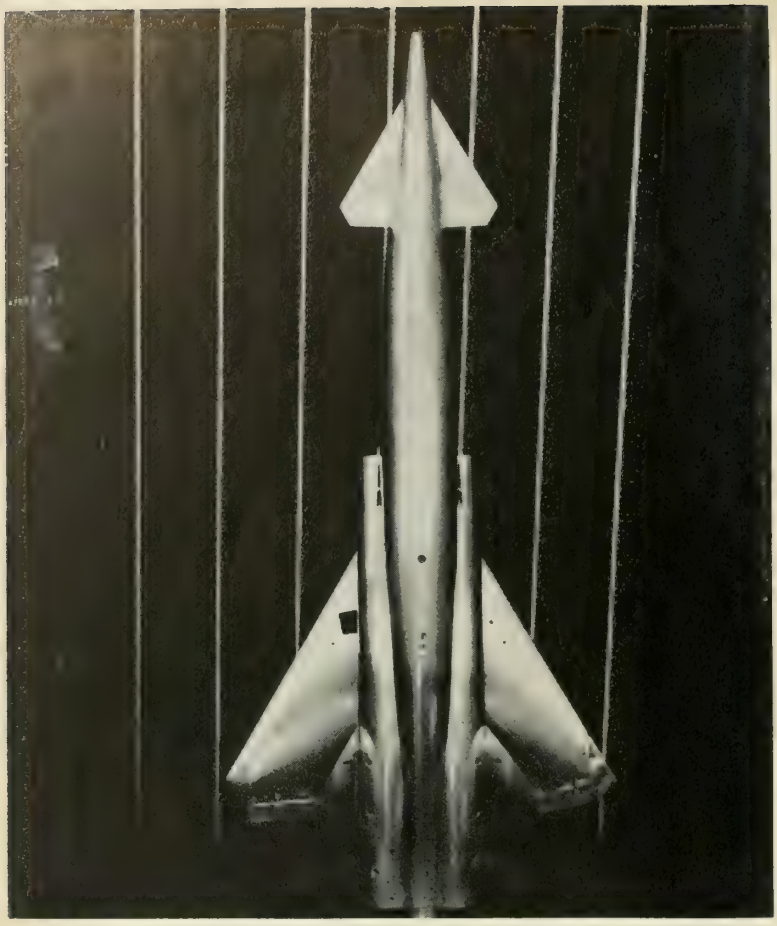
Total weapon system responsibility qualifies the *Navaho* program as a comprehensive, convenient pattern in studying today's missile projects and their attendant problems.

The problems cover practically the entire spectrum of both engineering and science. Fortunately, in *Navaho* we are beyond the research phase. We are largely beyond the basic engineering phase and into direct engineering, fabrication and flight test.

All missile programs face the very substantial task of achieving reliability. In completely automatic systems, the realization of reliability is extremely difficult but necessary before the military services can accept a weapon system for large scale stockpiling.

This brings us to the heart of our subject. We must have well trained, experienced personnel who can take the solutions of science and transform them into military hardware upon which the security of the U.S. rests.

The principle of jet power was clearly demonstrated in 100 B.C. by Hero of Alexandria, a Greek philosopher, with his rotating Eohlipile. But it has taken centuries before man was able to engineer this principle into the powerful and reliable jet engines which power our modern fighting airplanes. Today we are able to move from scientific principle through engineering to operating hardware in a relatively short time. This is to the credit of today's special types of engineer and the management groups in which he works.



In North American's X-10, a test missile for the *Navaho*, we proved out supersonic aerodynamic design and automatic guidance and control in less time, with less effort and with fewer missiles, than we had dared hope. This reaffirms the fact that time needed to reach the hardware stage can be significantly shortened. This of course, requires vigorous and extensive system development prior to the welding together of the complete weapon system.

Engineers engaged in advanced guided missile work find that they must be closer to scientific principles than the engineer of yesterday. Looking into handbooks for approved solutions will no longer satisfy many of today's problems. The man must be capable of understanding the basic scientific principles and translating them, often directly, into drawings.

Since the systems including those pieces of equipment which we normally call "hardware" have to be designed and developed by people, people become the most important factor.

The people involved, as well as the product, are getting to be more complicated—or rather what they have to know is more complicated.

For example, we have long had an engineer we called an aerodynamicist and another we call a thermodynam-

The fine detail of this large-scale wind-tunnel model of North American Aviation's NAVAHO test vehicle, the X-10, is a good example of the knowhow needed for missiles.

icist. Now we find that at the supersonic flight speeds we are working with today sciences of aero-and-thermodynamics merge into one—and so we have the aerothermodynamics engineer.

Much has been written and spoken about the so called heat barrier—the problem of aircraft heating up to very high temperatures as they pass through the earth's atmosphere at high speeds. When we begin trying to solve these problems we find that the shape of aircraft becomes vitally important. So the thermodynamicist becomes the aerodynamicist and vice versa.

Now there is another kind of engineer who has come into being in the missile business—and I might add, also in the aircraft business. We call him a systems engineer. Our personnel people sometimes refer to him as the general practitioner of missile engineers as compared to the specialist. Perhaps it would be better to call him a multiple specialist or a man who is a specialist in several, rather than one field.

There aren't many systems engineers today. After a solid base of academic training, the systems engineer must build himself a superstructure of broad experience in the missile industry. And so we really find him pioneering a relatively new field of engineering.

However, the systems engineer must be backed up by specialists in aerodynamics, thermodynamics, hydraulics, electronics, structures, propulsion and many other interrelated specialties.

Not so many years ago, a man in aeroelasticity and flutter, for example, also had to be an expert in dynamics. Today he must spread himself into another field—electronics—for modern electronic flight simulators and computers are the tools with which he works today.

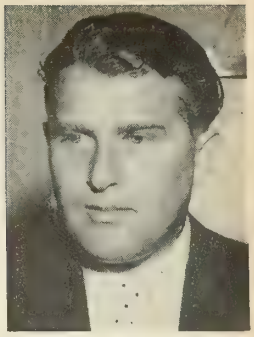
An engineer in design of automatic checkout equipment also requires quite a unique background. He devises complicated instrumentation tailored to make thousands of checks on specific missile types in preflight countdowns. To do all this he needs to know avionics, hydraulics, pneumatics and related special fields.

From every point of observation, we find the engineers and scientists growing as the horizons of the industry expand. Those who make the most significant contributions are almost always the ones who are a combination student and practical engineer.

Both industry and our schools are rising to this new engineering challenge. I know of no major aircraft manufacturer who is not spending considerable money and time for on-the-job training. These same industries are contributing to colleges to help them set up courses in such new fields—often at a graduate level—as ceramics, electronics, rocket propulsion, etc.

While our total effort in missiles today is directed toward defense and military application, the general body of scientific and engineering knowledge being accumulated will certainly find application in non-military technology.

First will come uses of new techniques and materials developed in missile research. These will include utilization of new heat-resistant materials, new methods of metal working such as chemical etching, new techniques in heat-treating, adhesive bonding and welding.



Gains in electronic growth and expansion already show themselves in computers that multiply man's computing ability a million-fold—in automation systems that operate oil wells, man machine shops and printing presses like human experts.

Sub-miniaturization shows its new importance in Tom Thumb size transistorized radio and TV sets, to name only two broad commercial applications. The field of instrumentation is rich in the applications to consumer products.

Out of the development of powerful liquid propellant rocket engines has come high speed pumps and turbines for which I'm sure many future commercial applications will be found in addition to ones we already know.

It is also significant to note that tomorrow's pilot is finding that he needs a sound engineering background if he is to meet flight challenges of the almost immediate future. While we have been designing pilotless missiles we have also been designing manned vehicles that called for new approaches. These will allow a pilot to function at new extreme altitudes and speeds. This leads us to the study of aero-medicine and human factors research.

We find ourselves faced with the need to extend the operating limitations of both men and machines. Out of this may well come new combinations of technical and engineering skills the scope of which we have only a bare indication. ★

Progress Toward Space Flight:

Space Travel and Our Technological Revolution

By Dr. Wernher von Braun

Army Ballistic Missiles Agency

DURING THE FIRST three months of this year hardly a week has passed when the newspapers did not report on some gathering of scientists and engineers who were discussing space rockets and astronautics. A few years ago that very word—astronautics —was virtually unknown, and most people bothering to stop and reflect about its meaning would at best have taken it as a mild joke.

Today one of the largest and best reputed aircraft companies in the United States has its $40-Million Astronautics Division with thousands of employees. In those astronautical meetings of scientists and engineers arguments no longer rage about the feasibility of this or that paper proposal, but about test programs, schedules, budgets, tracking organizations and rocket hardware. There can no longer be any doubt about the fact that Astronautics has reached the stage of practical engineering.

What causes this sudden interest of man in the conquest of outer space and the exploration of worlds beyond our own? As it behooves a group of astronautical hopefuls let us for a moment assume the point of view of those little green men who allegedly have been observing us for centuries from their flying saucers.

Let us see what has befallen the inhabitants of this planet earth, who after several hundred thousand years of quiet, self-sufficient earthbound existence, suddenly have learned to fly and who now, a mere 50 years later, are making visible preparations for ventures outside of the atmosphere and even beyond the gravitational field of their abode.

From their all-encompassing orbiting vantage point our little green friends would have noticed that from the beginning of the 19th Century on, strange activities set in on this planet the like of which had never before been seen. They observed how iron tracks were laid across the land.

Soon a string of coaches, pulled by a smoking and puffing something, was seen moving along the rails. Carriages, hitherto horsedrawn, were seen speeding along without the benefit of horses and humble dirt roads gave way to broad cross-country avenues which soon filled with dense traffic.

Artificial lakes appeared on the face of the earth. Wire lines supported by filigree steel towers were strung from these lakes to neighboring cities. And while these cities stayed ablaze with light after sunset, a forest of smokestacks soon began to hide them in a veil of smog.

As experienced, cosmopolitan-minded travelers through the galaxies, our visiting astronauts would have concluded that the inhabitants of this planet earth were beginning to learn how to harness the forces of nature. From their experience with other inhabited worlds, they would have known that man and his earth were in the midst of that most crucial and painful period of their existence, the transition from the pre-technological to the golden technological age.

Proud as we may be of our steady advances in the natural sciences and engineering, of all the little daily improvements here and there that we are wont to wrap up in that little word

"Technology and ethics are sisters. While technology controls the forces of nature around us, ethics controls the forces of nature within us."

It is with pride and humility that m/r reprints herewith the deliberations of a thinking man. Major General John B. Medaris, Chief, Army Ballistic Missile Agency, has described Dr. Wernher von Braun as one of the most intensely patriotic Americans alive today. He also possesses a mind that is insatiably curious, penetrating and probing. He can discuss with clarity and intelligence space flight, rockets for peace or war, the world's great religions, Europe's first industrial revolution or the motives of Tamerlane. With the new weapons described as "ultimate" and with man about to break loose from his confining earthly sphere and extend his environment to infinity, the interrelationship between God and science is no longer a subject merely for theoretical discussion but is a matter of vital practicality—a prime consideration in the struggle for survival of the species. Dr. von Braun's profound presentation was originally heard by a scant two or three hundred people at the Annual Spring Meeting of the American Rocket Society in Washington, D.C. It should be brought to the attention of everyone concerned with the affairs of mankind. Special reprints are obtainable from MISSILES AND ROCKETS *magazine.*

The Editors

"progress", we seldom stop to think how deep-reaching the effects of this technological revolution have been on virtually everything that has happened on this planet during the last 150 years.

Perhaps the fact that man's occupation with the natural sciences can be dated back many centuries, that names such as Aristotle, Copernicus and Newton are generally accepted landmarks of man's growing scientific enlightment, has somewhat obscured the picture. We should not lose sight of the fact, however, that while these and other great men searched for knowledge and truth about God's world, they did not concern themselves in the least with the application of their scientific knowledge to the plight of man.

It is an undeniable fact that only since the beginning of the 19th Century something absolutely new and unprecedented has entered human history: the determined attempt to liberate the human race from the yoke of heavy physical labor through the harnessing and utilization of the forces of nature.

All the great civilizations of the past were based on some form of human bondage. The ancient had outright slavery. In the Middle Ages it was called serfdom, but for all the fine distinctions historians have tried to make between these terms the basic idea was always the same: In pre-technological times a civilization was looked upon as an organism, like a flower. And for a flower to bloom and to turn its blossom toward the light, its roots, which give it the strength, must dig in the dirt.

For humanity's survival a certain amount of unpleasant, heavy labor had to be performed. Mechanical means for doing that dirty work were unknown. Therefore human bondage for all but a happy few appeared to be a God-given necessity, and a logical and even vital institution in the pattern of the creation.

This simple logic seemed so obvious that even the great thinkers of antiquity—and among them were the originators of many of the most fundamental ideas of the Western World—found nothing offensive in it.

Technology, the submission of the forces of nature, is man's first and only chance to abolish effectively the curse of slavery, whatever its name. Only with the help of technology can we hope to build a cultural organism in which not just a favored few, standing on the shoulders of the multitude, may blossom, but one in which everybody has an equal chance to deploy his capabilities in the light of universal freedom.

We are on our way to this lofty goal, but we have not yet attained it. In fact, in its first phase the technological revolution probably created more new problems than it solved. It speeded up the growth of the large cities where many a farm boy traded the freedom and beauty of life on the farm for the ugliness of a crowded existence in a smokefilled industrial city. It created great riches on the one side and inadequate benefits for the workers on the other, with resulting unrest.

It created a new representative of human bondage—the proletarian, a slave who was no longer for sale but for rent. Theoretically of course, the proletarian was a free man, but the penalty for his deserting the job was still the same as that for the slave of ancient days—death by starvation.

We are still surrounded by sad remains and reminders of this early phase of the technological revolution. The lot of many miners is still reminiscent of that of the Biblical Hebrew slaves who built the pyramids, and the monotonous job of an assembly-line worker still has a conspicuous resemblance to that of an ancient galley-slave.

But the new paradise which the technological revolution promises is no longer a mere silver lining on the horizon. We have unmistakable signs of its imminence. Our highways are no longer built by road gangs toiling with pick and shovel but by cigarette-smoking operators sitting on heavy road-building machines. Assembly line workers are rapidly being replaced by electronically controlled automation of manufacturing processes.

The stoker of an electric power plant who, half a century ago, half-naked and sweating had to shovel coal into blazing fires, now sits in a tile-covered control room clad in a white gown and monitors the instruments of the automatic fuel controls. No longer does he live in a cold water city flat. He has his own little suburban home and drives his own car.

The technological revolution has brought about an entirely new set of unprecedented problems for the organization of human existence on this planet. In fact, most of today's political problems are a direct consequence of the technological revolution. Capitalism, socialism and communism were unknown words before the invention of the steam engine. So were terms such as trade unions, raw material bases, transoceanic supply lines and oil concessions.

One of the most crucial problems of our times lies in the fact that the very nature of technology is dynamic, while the forms of political law and order which mankind needs for peaceful co-existence are fundamentally static.

The contradistinction between the static forms of political order and the rapidly changing technological conditions is likely to create in the future, as it has in the past, a continuous source of conflict. For every major invention changes the basis of human existence far more profoundly than a treaty between nations or an agreement between statesmen.

The overshadowing prominence of the technological revolution is impressively manifested by the fact that it knows no national boundaries. Its unmistakable signs—smokestacks, roads, railroads, power lines and industrial cities—can be found on both sides of the Iron Curtain, in America and Europe, the birthlands of modern industry, as well as in historically agricultural Russia and China.

It has spread like wildfire to South America and Australia and is establishing ever firmer footholds in the darkest parts of Africa. Even spiritual India—where since time immemorial men had held that the only road to human happiness was abstention from worldly ambitions, goods and riches—is now competing with the rest of the world in the construction of hydro-electric power plants and the operation of transcontinental airlines.

But while the enthusiasm for the technological revolution may be the same on both sides of the Iron Curtain, there are truly fateful differences in its implementation.

We in the West take account of the fact that the prime mover of technological progress is man himself; man, with his hopes, dreams and imaginations; man, with his enthusiasm and pride of accomplishment; but man also with all his foolishness and weaknesses, with his personal ambition, greediness and thirst for pleasure. We believe in a free society where man can pursue his own dreams, follow his own ambitions and form his own life.

We believe in limiting his activities only to the extent as they might harm his fellow citizens, and we are entirely ready to accept even his weaknesses such as egotism and search for easy profit as natural and human and smilingly put them to work.

We subscribe to the belief that the rich man's luxury of today is the average person's consumer goods of tomorrow. The result of this general attitude is an economy governed by an all-out effort by everybody to be more effective than his competitior.

We must push the spokes of the wheels of progress in order not to be run over ourselves. But while we are throwing everything we have into the fight, we must concede that we are using some of our strength, not against the forces of nature which we set out to harness, but against our business rivals.

On the other side of the Iron Curtain this free-wheeling way of going about the business of progress is considered wasteful. In accordance with the basic communist creed that there should be no private ownership of means of production, the State took over the management of the factories and laboratories.

Not man himself, as a warm-blooded individual, was to be the hub of progress but an all-embracing and all-controlling master plan. Whole series of consecutive Five-Year Plans were thus enacted which, on paper at least, provided an admirably dovetailing set of schedules for the organization of industrial development and progress. The gear box of this gigantic machinery, the purpose of which was to convey the driving power to its many outlets, was grandiose, but soon it became apparent that what had failed was the motor itself: man.

At first, communist revolutionary enthusiasm was supposed to step in and provide the driving energy which had taken a nose-dive when, because of lack of incentive, the personal interest of the individual had faded.

After the storm of enthusiasm had blown itself out, an appeal to proletarian solidarity was called upon to replace it. And after this had failed, too, naked terror was tried as the last resort.

While it succeeded in keeping the wheels of the machinery from grinding to a complete stop, the results were so disappointing that the Soviet leaders themselves realized that the re-introduction of incentives—which, of course, was tantamount to a differentiation in the standard of living—was an absolute must if their great Soviet economical experiment was to be saved from monumental failure.

The Soviet leaders were confronted with yet another problem which compelled them to return to an effective incentive system. While their Communist Revolution could be run and was run by political amateurs, the technological revolution can only be run by professional scientists and engineers.

Without an adequate educational system capable of producing a steady supply of scientists and engineers to direct the work in their factories and laboratories, they could not hope to catch up with the Western World's advances in technology. And without continued progress in the realm of the technological revolution, their political revolution would have been doomed. For it would have been demonstrated for all the world to see that communism was not capable of industrially organizing a backward country.

We know how frighteningly successful the Soviets have been during the past decade in producing ever-increasing numbers of scientists and engineers. But while this development—and its consequences on the future economic and military position of the West—should be given all the serious consideration it deserves, we should not lose sight of the fact that it contains a very strong element of truly bright hope. For there can be no scientific education without encouragement of a critical attitude on the part of the student.

Dr. Wernher von Braun with a model of his famous "pioneer model" manned space rocket.

There can be no scientific progress without a healthy disregard for the printed word and for dogmatic truths established by authorities or famous predecessors. And no man can be a true engineer unless—like a medical man—he looks upon his job as a calling, as an opportunity to make a contribution to the technological progress for the betterment of man's life on this earth.

I am convinced that the education of those hundreds of thousands of scientists and engineers in the Soviet orbit will have its lasting effects on the Soviet system itself. It will make it more and more difficult for the few to impose their will unchallenged upon the many. Those hundreds of thousands of critically and scientifically trained minds will cause more discussion, criticism and "feed-back from the bottom". They will, in general, mellow the Soviet system's monolithic structure. But most important, they will, in the long run at least, enhance the role of ethics in the Soviet system and will reduce the role of momentary expediency.

It is my firm belief in the ennobling effect which this mass-education program will have on the Soviet system, that affords me my optimistic outlook on the future of mankind.

Our present, sometimes seemingly hopeless, political impasse with the governments behind the Iron Curtain shows us with a frightening clarity that all of man's scientific and engineering efforts are in vain unless they are performed and utilized within a framework of ethical standards commensuate with the magnitude of the scope of the technological revolution. The more technology advances, the more fateful will be its impact on humanity.

If the world's ethical standards fail to rise with the advances of our Technological Revolution, we shall all perish. Let us remember that in the horse-and-buggy days nobody got hurt if the coachman had a drink too many. In our times of high-powered automobiles, however, that same drink may be fatal!

The successful release of atomic energy presented mankind, in one neat package, a simple choice between hundreds of cheap electrical slaves for everybody—and universal destruction. With the rocket, the technical differences involved are even less. Any ballistic missile capable of carrying a nuclear bomb over an intercontinental range can be modified to carry a few instruments to the moon. In both cases the question of which of the two loads will ultimately be placed into the nose of such a missile is not in the hands of the scientist or engineer who builds the rocket. It is solely dependent on what

ethical standards will prevail in the world in times of crises.

Technology and ethics are sisters. While technology controls the forces of nature around us, ethics controls the forces of nature within us. But while technology is a mere 150 years old, the problems of ethics have occupied the minds of the greatest thingers on this planet for several thousands years.

I think it is a fair assumption that the Ten Commandments are entirely adequate, without amendments, to cope with all the problems the technological revolution not only has brought up, but will bring up in the future. The real problem is not a lack in ethical legislation, but a lack in day-to-day ethical guidance and control.

Prior to the Renaissance the church applied this tight individual guidance to emperor and beggar alike. But when science freed itself from the bonds of religious dogma, thus opening the way for the technological revolution, the church also lost much of its influence on the ethical conduct of man.

It has been frequently stated that scientific enlightenment and religious belief are incompatible. I consider it one of the greatest tragedies of our times that this equally stupid and dangerous error is so widely believed. But it is easy to see why so many people fall for it. We instill in our children a tremendous amount of what we call factual knowledge, but we deny them knowledge of what we do *not* know: "You can't teach what you don't know yourself," is the cheap excuse. But by not telling the children about nature's mysteries, its infinite number of unexplained and unexplainable miracles. we deny them that most important dowry for their future life, humility.

Nothing has probably retarded human progress more than idolatry of our own achievements. By adoring our own scientific achievements we kill humility, the mother of any true scientific progress. By adoring our own technological advancement we kill the urge to come up with a better product.

Nature around us still harbors many thousands times more unsolved than solved mysteries and for all our scientific enlightenment we know more mysteries today than when the technological revolution began. So there is no reason why God cannot retain the same position in our modern world that He held before the natural sciences began to pierce through the walls of dogma erected by the church.

Science and scientists should put this simple but widely unknown truth across to people everywhere. With all the modern means at our disposal, with schools, churches, educational institutions, press, radio and television, we should tell the world that religion and science are not incompatible; that, on the contrary, they belong together. For only with God reinstated in the heart of the world, will He furnish mankind and its leaders the ethical guidance through the dangers and pitfalls of the technological revolution.

The fear of the nuclear bomb, the restlessness of modern city life, the standardization of many consumer goods with its resulting levelling effects on tastes, fashions and even opinions—in short the unpleasant aspects of our technological age—have caused many people to decry technology as a whole and to preach return to the simple life. But for any civilization that has entered the road of technology, and there is hardly any civilization on this planet left that hasn't, there can be no return. For it is in the nature of the technological revolution that it first destroys the existing economic pattern before it can effectively replace it by a superior one. Thus for a country dedicated to industrial development to return to the simple life would mean complete economic ruin. There is only one way to overcome our present difficulties, namely to pursue the technological revolution with even greater zeal and determination.

But in order to keep the technological revolution alive, it must be continuously incited by research. Only by feeding it with new discoveries and new inventions will it continue to roar along the road of progress.

One of the main ingredients of any research or exploratory work is just plain curiosity. It is as unwise as it is unrealistic to insist on justifications for new research projects on the basis of their immediate purpose and their potential practical application. Technological history abounds with examples proving that it is simply beyond the capability of man to predict what will follow in the wake of a major discovery.

I do not know of an example which could illustrate this simple truth more strikingly than that grandiose project so dear to the heart of every true rocket man: flight into outer space. How often have we heard questions such as "Why should we try to establish artificial satellites?" or "Why do you want to go to the moon?", questions hopelessly ignoring the mainspring of human existence. The simple fact is that we have the technical means at our disposal to go about these challenging tasks; therefore, the only really justified question should be: "Why should we *not* do it?"

Space flight is not just one of a great number of technological projects of the near future. It is in a class all by itself because it means, in the broadest sense of the word, an extension of man's activities beyond the realm of his home planet. Today when we talk about space flight we think mainly of rocket ships and their engines, of guidance and navigation methods and of the technical means for controlling the environmental conditions aboard a space ship.

These engineering problems are really only part of the broad aspects of space flight. They are a very important part to be sure, because it is still the lack of adequate transportation equipment that prevents us from traveling to the moon and to Mars. But once these means of transportation are available, research activities beyond our own planet are bound to fan out tremendously.

We can get an inkling of what we may expect in this regard from the rush of research institutions on the rather modest payload accommodations for scientific instrumentation on the *Vanguard* satellite rockets. Thus we may safely assume that once laboratory space in manned space stations is for rent, we shall run into all kinds of professions up there which have very little concern with the engineering aspects of rocket ships.

Of course, we shall find astronomers and astrophysicists, radiation experts and medical researchers, meteorologists and reconnaissance men up there. But commercial interest will have entered the field, too, and we should not be surprised to find a sign at some door indicating a maintenance headquarters for an orbital ultra high-frequency message relay center for a television relay station.

But once man sets foot on the moon and the first voyages to our nearer planets are in preparation, new professions will join the cause of space flight. Botanists and zoologists, geologists and archeologists, mapping experts and may be even interplanetary mining prospectors will be represented in man's first interplanetary expeditions.

It is difficult to think of a field of human endeavor that will not be involved in man's greatest venture. Thus it is only natural that space flight has moved to the forefront of scientific research.

It is the ultimate objective of our great technological revolution to free man from the slavery of heavy physical labor, to elevate mankind from its historical bondage to a race of masters, in whose service toils an army of mechanical and electrical slaves.

This liberation through technology will enable man to devote more time to think and to dream. It will raise all our civilizations to levels never before attained in human history. Space flight will free man from his remaining chains, the chains of gravity which still tie him to this planet. It will open to him the gates of heaven.★

Two seconds to "FIRE"...the time when your instrumentation cables must work

Are you responsible for any of the equipment involved in scenes of this kind? Any of the instrumentation or telemetering devices?

If so, you well know how little can be left to chance when a $100,000-plus pre-dawn "shot" is scheduled.

Even minor cable trouble at a time like this can be crucial and costly, especially if it happens on the equipment involved for which *you* are responsible.

That's why it's important for you to insist on electronic cables with *maximum built-in reliability.*

Quiz yourself on cable

Here's how to get this kind of reliability. Ask yourself these questions about the cable that's to go into your own equipment:

1. Who is the cable supplier? Has he:
   a. Thorough knowledge of electronic wiring problems?
   b. Engineering and research skill in developing special cable?
   c. Complete facilities for producing custom-built or specification cable?
2. Are his cable conductors full-size, uniformly annealed and precisely stranded?
3. Are his insulations and coverings uniformly applied compounds that have proved workable, dependable?
4. Can he supply those newly developed materials that might be needed?

You'll find all of these qualifications met in full measure by Rome Cable

Millions of feet of Rome wire and cable have already been installed in electronic gear for military and commercial uses. More is ordered every day.

When you require cable that must not fail—or which must meet unusual specifications—we can very probably help you. Simply contact your nearest Rome Cable representative—or write to Department 422, Rome Cable Corporation, Rome, N. Y.

ROME CABLE

CORPORATION

We have many reasons for suggesting Firestone's Guided Missile Division as the likeliest spot for nurturing your brainstorms. Most important is our small-project approach to large-scale engineering problems. This select-team effort gives the highest possible ceiling for individual creativity. Within a reasonable framework of intelligent guidance, it makes the most of every man's potential, keeps frustrations and lost motion at a minimum.

You'll find a maximum of professional opportunity whether you join Firestone's development program for the Army's Corporal in Los Angeles...or the new Engineering Lab in idyllic Monterey—Carmel-by-the-Sea. In either spot, your family (and you) will fall in love with the Golden State of living!

Please write us today if you are brainstorming in these fields:

PROPULSION PROGRESS

Some twenty years ago, a backyard static test of a new chemical propellant combination was likely to add some 25 seconds to the increasing specific impulse climb at a cost of a few dollars. Today we are groping for increases of only a few seconds at costs of from four to six orders of magnitude greater. And, our propellant future, limited by known compounds and problems of stability, seem to be headed to a maximum level plateau of about 300-350 seconds for working systems. It is expected that it will take us some ten years to reach this ultimate in chemical propulsion.

Despite this now very gradual climb, there is a vast technology and a new industry being forged to support the progress that already has been made. Here then is where the real progress is being made—concerned with production, stability, logistics, economics, and the expanding market of applications.

Biggest propulsion advance lies in the field of "exotic" fuels. Since we had only a handful of good oxidants to play with, it seemed logical to look for improvements—particularly heat content—in our fuels. The light metals and the various hydrides all offered higher heats of combustion per unit volume than conventional hydrocarbons. These exotics are now getting into production. Known under the name of "Zip" or "Hi-Cal," the exotics apparently are hydrides of boron which can be used directly or as a "Mickey" for common hydrocarbons. Presumably the exotics will be slated for use in jets, ramjets, or in rocket systems.

Although details of the exotics are just starting to trickle out, it is probably safe to say that the laboratory phase has been completed and that the main effort is now centered in building production plants. Within the next two years, the production of exotics will have assumed the tonnage scale. Only then will a true balancing out take place. This balancing out will weigh the actual operational advantages against such powerful factors as handling and logistics, demand versus production and overall cost. Commercial applications of the exotics hang on the comparison of laboratory expectations and actual practices.

Right now, straight LOX seems to be the choice of all large missile systems. However, the days of LOX for some applications are already numbered. Several years of work have gone into the preparation of pure ozone and, as the exotics are used to "spike" the hydrocarbons, ozone will probably be used for increasing the oxidizing power of LOX. As yet, however, straight ozone is a bit difficult to handle and ozone technology has not yet operated on any scale but laboratory operations.

Liquid fluorine (or fluorine compounds) is closest to displacing LOX. Nearly everyone agrees that fluorine offers a good balance between high flame temperature and low molecular weight. Since fluorine will probably offer the ultimate in oxidizing potential and give nearly the theoretical limit for chemical systems, the path for fluorine is well marked. And fluorine, unlike ozone, has well established handling techniques and is now being produced on a tonnage basis.

For smaller systems, nitric acid will continue to be a popular propellant. Other propellants such as hydrogen peroxide, ethylene oxide, the alkyl nitrates are already being relegated to auxiliary propulsion systems. Research, however, has failed to turn up stable liquid monopropellants in the 200-250 sec range.

In order to come up with high energy monopropellants, two "dirty" systems are under investigation. One employs what might be called a composite liquid propellant, premixed amounts of oxidizer (such as nitric acid) and fuel. Stability is the big problem here. The ten foot pole is gradually getting shorter as the "gunk" liquids are appearing more attractive to the engineer who formerly would only consider pure or "clean" liquids.

The gunk propellants—gels, slurries, pastes, suspensions, etc.—are being considered for new systems—particularly where high heats of combustion and high volumetric loading are essential.

In between the liquid and solids are the hybrid systems. Two systems have been evaluated in hybrid rockets. One used liquid oxygen which burned a solid polysulfide rubber while the other used hydrogen peroxide and a polyethylene plastic fuel. Neither systems have shown great advantages over either the true liquid or solid system.

This does not necessarily hold for the reverse case where conventional or exotic fuels are used in combination with pure solid oxidants. Work in this latter system, however, has been very sparse. The effort going into the solid fuel ramjet is not as sparse. Several groups have been engaged in development and several systems employing solid fuel ramjets are in the works.

The biggest single important solid propellant development has been concerned with scale-up for producing really large single grains. Both composites and double base castable propellants have evolved which now permit grains of almost any size. However, just how large are current big grains is difficult to ascertain because of security reasons.

It is probable that present solid propellant technology can give grains of about 1 million lb-sec and that within 2 years we will have solid rockets as large as the V-2 (ca 4 million lb-sec) and that in 5 years an operational solid propellant IRBM will have been developed.

At the other end of the solid propellant scale, ammonium nitrate is ushering in the era of low cost, medium energy sources. It is already being used in the area of RATO and boosters. Biggest area for these propellants are APU's and a host of industrial and commercial applications.

Newest entry into the propulsion field was the continuous detonation engine. Although thrusts are yet small, the specific impulses are quite good. Since this work is yet in the laboratory stage, extrapolation to large-scale hardware is difficult.

The next propulsion plateau above chemical propellants will probably be the use of nuclear energy. In the atomic rocket, propulsion progress is of a mixed nature. The stretching out of our aircraft nuclear propulsion program has been blamed on excessive weight and a high level of radiation. In the power reactor field, however, progress is being made in increasing heat transfer by increasing pile temperatures. Developments now taking place in other realms, however, may never make the thermonuclear rocket practical.

There is a great deal of interest in non-heat engines. Two entries for study of ion propulsion have been let and there are a host of researchers working on electrical and magnetic particle acceleration. Fusion energy for rockets is a hope, although distant. And the ultimate of all propulsion schemes—the utilization of photons—still awaits a laboratory foundation.

WHY DOUGLAS ENGINEERS AND SCIENTISTS GO FURTHER...

At DOUGLAS

...your missiles assignment can be as big as your talents

Now in its 16th year, the Douglas missiles program is projected far into the future by such exciting new projects as THOR

Out of such veteran projects as Nike and Honest John are coming fantastic new missile systems to challenge the finest engineering talents in the land.

Since early in World War II, Douglas has been engaged in missile projects of prime importance. New engineering teams are constantly being formed for research, design, development and production. Engineers advance rapidly as Douglas expands its leadership in this challenging field.

You are stimulated to accelerate your career by the importance of each assignment ... by the help of your associates who are recognized experts in missile work ... by the vastness of opportunity for engineers in this company that is run by engineers.

There is no more promising future than that which awaits you in the Douglas Missiles Divisions.

THOR—*an intermediate range ballistics missile now under development—has top priority in our country's program for national defense.*

Engineering Progress in Air Force Rocketry

By Frederick I. Ordway III and Ronald C. Wakeford

RECENT TEST FIRINGS of nuclear armed air-to-air rockets spotlight the progress made in aerial warfare. Although overshadowed by the more spectacular developments of IRBMs and ICBMs, new advances in aerial rocketry have caused revolutionary changes in the tactics of plane-to-plane combat.

The design and development of a successful air-to-air missile is a complex proposition with enough variables to keep teams of engineers and scientists busy for months and years. Not only must the missile operate in harmony with the aircraft that carries it, but all internal mechanisms must be carefully mated with the missile itself.

The *Firebird* represents a relatively early attempt by the Air Force to provide an accurate liquid-propelled air-to-air missile for operational units. It was developed in about two years by the Ryan Aeronautical Co., and carried the official designation XAAM-A-1. It was first tested in 1949, was carried on external launching racks.

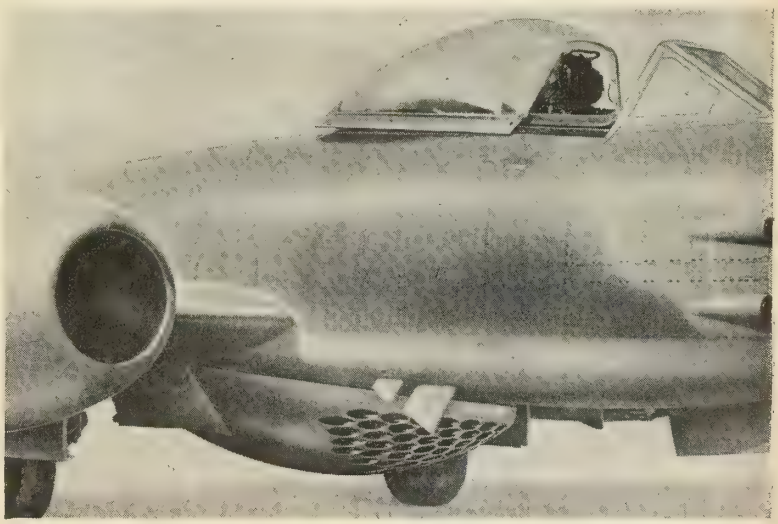
Firebird incorporated a semi-active radar homing system and a proximity fuze. Control surfaces were located on the wings and fins. The carrying airplane housed the search radar.

The 7½-foot missile (10 feet with booster) had two sets of cruciform plastic wings with control and stabilization surfaces. The basic structure was conventional aluminum alloy sheet. Such aircraft as the B-26 and *Twin-Mustang* F-82 generally carried four of the 600 pound Firebirds, which could be fired alone, or in groups of two or four. The overall development program cost about $2 million.

Mighty Mouse

For years America's only operational air-to-air rocket was the reliable 2.75 inch, folding fin unguided *Mighty Mouse*. If hostilities were to break out today it would continue to be a standard defensive weapon. *Mighty Mouse* was a Naval Ordnance development of the successful German R-4M rocket of World War II, and has been fired not only from such Navy aircraft as the *AD Skyraider*, but flown many Air Force fighters. The *Aeromite* is much like the *Mighty Mouse*, using a somewhat different propellant.

The rocket uses a proximity fuze, and has fins that fold out at launch. Some airplanes, for example the F-89 and -04C, carry them in wing tip pods to improve dispersion, firing about twelve in a quarter of a second. Other planes, such as the F-86, fire them in single volleys of 24, leaving the aircraft at 200 miles per hour.



The F-89D can carry 104 of these 2.75 inch rockets and fire them electronically. A T-110 rocket gun has been developed to fire the *Mighty Mouse*.

Mighty Mouse has been in production for years and is used throughout the squadron service. It is used in practice shoots against aerial towed targets like the radar-reflecting nylon marquisette units currently in vogue. B-45 and B-57 aircraft generally tow the targets for practice shooting with the *Mighty Mouse*.

There is considerable pilot disagreement about the relative effectiveness of launching salvos from trays under the nose and from wing-tip pods. While accuracy from the former position may be high, pilots point out that by loosing your rockets from wing positions you can get more rounds on a target per pass, better dispersion characteristics, and hence a greater chance of destroying it.* In the case of the *Mighty Mouse*, cost is not an important factor which helps make it an attractive defense item.

Eglin Air Force Base is supposed to have a fully developed two-inch replacement of the *Mighty Mouse*, which was shelved because of long-term *Mighty Mouse* commitments, and

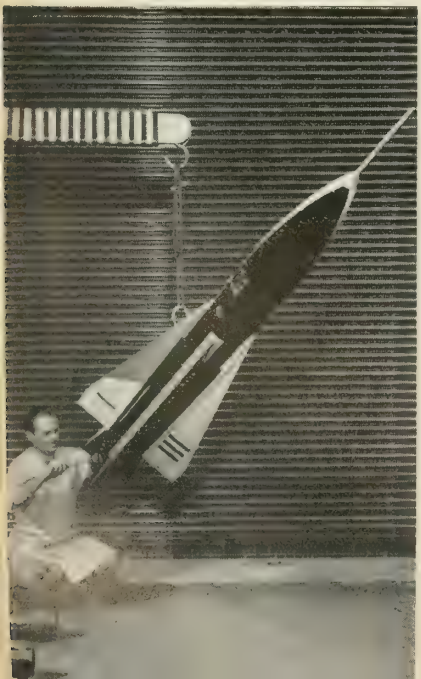
* A dispersion of 20 miles means a deviation of 20 feet for 1000 feet of travel. Unguided rockets are normally spinstabilized, though longitudinal fins often provide prime stability. The higher the number of rpms, the more dispersion is reduced.

Swiss Oerlikon's bid in the small air-to-air folding fin rocket field. This launcher for 76 of the five centimeter diameter projectiles is mounted on a British Gloster Meteor twin jet fighter. Some pilots perfer the straight ahead firing of this center mount to the converging pattern obtained when the rockets are fired from wing-tip pods.

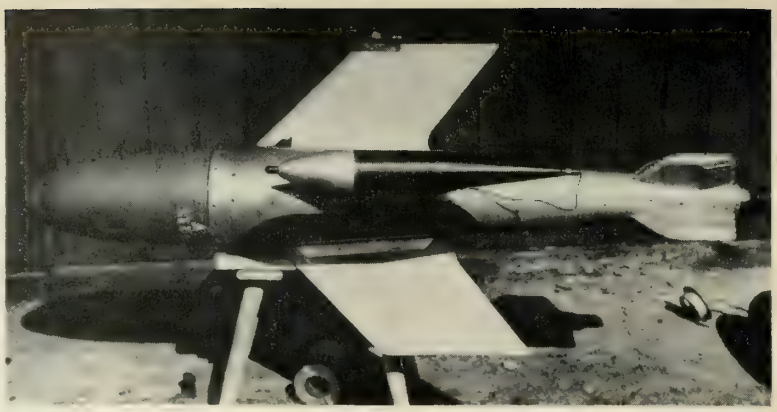
because of current emphasis on air-to-aid guided weapons.

Zuni

Named for the Pueblo Indian Tribe, the new Navy *Zuni* air-to-air 5 inch high velocity aircraft rocket was developed by the Ordnance Test Station, China Lake, Calif. This folding fin, solid propelled weapon has been extensively tested by both BuOrd and the Fleet Operational Development Board, and is now approved for operational use. It has twice the velocity of the HVAR of World War II fame.



The *Zuni* launcher can accommodate four rounds and not only launches the rocket but is also the storage case. It is jettisoned after use. The elimination of the normal packing case is expected to result in considerable time savings. *Zuni* is also designed for air-to-surface applications.



The unguided rocket generally has good static stability and reports indicate that *Zuni* is no exception. Detailed performance figures, however, are not yet available. In guided rockets, on the other hand, one must allow for a large displacement of controls to maintain a given flight path or to change direction. With relatively low static stability, they enjoy a high maneuverability rate.

Sparrow

There are three *Sparrow* missiles now in existence: *Sparrow I* (AAM-N-2), *Sparrow II* (AAM-N-3) and *Sparrow III* (AAM-N-6), developed respectively by Sperry-Rand, Douglas and Raytheon. *Sparrow IV* is apparently still under the cognizance of Navy BuAer, and as far as is known no contractor has been designated to build it.

An approach to bomber defense this Cornell Aeronautical Laboratory missile design looks like but actually preceded that of the HAWK.

German X-4 was developed as a wire controlled, rocket propelled, gyro stabilized missile. It employed a proximity fuse. By the time World War II ended it was almost ready to use.

Sparrow I, first produced in 1951, is manufactured by the Sperry-Farragut plant in Bristol, Tenn. and at the Douglas Aircraft Co. in Calif. A beam-rider, it has a semi-active terminal homing device developed by Sperry and Raytheon. It is considered very accurate up to five miles.

Sparrow II, with an active homing system is to be used by the Royal Canadian Air Force to replace its abandoned Velvet Glove development. It has a rounded nose, trapezoidal form, and shortened fins.

Raytheon will build *Sparrow IIIs* at Sperry's Bristol plant when *Sparrow I* phases out. This new missile has been mounted on McDonnell F3H Demons.

It is radar guided, has a blunt nose and tail surfaces similar to *Sparrow I* with a smaller degree of sweepback. Raytheon has a $60-million Navy contract for its air-to-air work. *Sparrow I* has seen wide operational use on McDonnell F3H2N *Demons*, Chance-Vought F7U3M *Cutlass*, and other aircraft.

Falcon

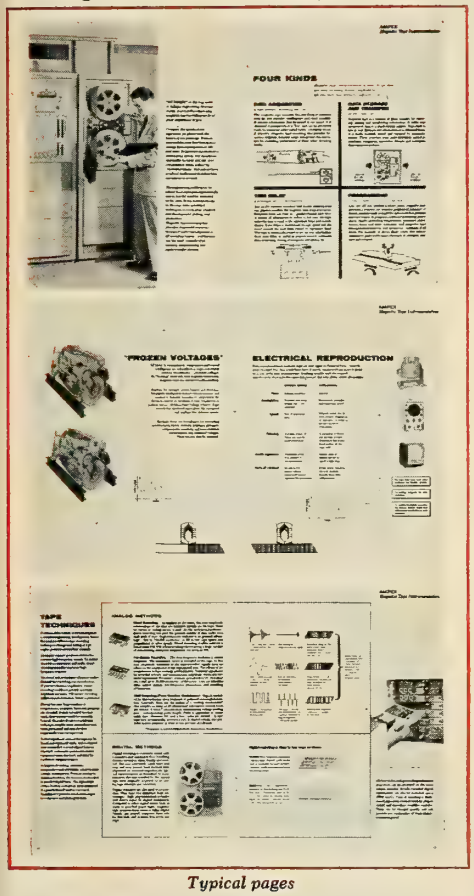
Under development since 1947, the GAR-98 *Falcon* is a product of the Hughes Aircraft Co. and Philco. The three-to-five mile missile has been carried by a wide variety of aircraft including the F-86, -89, -94, -100, -102 and CF-100, and was first tested in 1950. The F-89H was the first operational aircraft to carry *Falcon*, which has been mounted on both wing pods and pylons.

In the pod mounting layout, three *Falcons* are often carried on the periphery. The pod itself contains three 7-battery 2.75 inch rocket panels. An interesting feature of the *Falcon* is its temperature sensitivity. For this reason special heaters are used to maintain the firing temperature. In solid rockets this temperature sensitivity is expressed as the percentage change of thrust for each unit of temperature change and generally runs from 0.0025 to 0.014 additional pounds of thrust per degree. On hot days you get a higher thrust while lower than rated thrust may occur on cold days if no heating blanket is used.

GAR-1 (Model 1) is six feet long and six inches in diameter, weighing 112 pounds. Newer models are longer and heavier, and have a greater range. Four have been placed in production since the inception of the program. The latest is the GAR-1D, featuring major control changes. Since atomic explosives reportedly can now fit into four-to-five inch diameter projectiles, *Falcons* with atomic warheads may be approaching.

Falcon may eventually be made in an infra-red version using a beam rider guidance system with semi-active homing. Whether Models 2 or 3 will have it is not known. The missiles can be fired from any positions including underneath and in salvos beyond the defensive range of a bomber.

As production goes up, costs go down. A few years ago figures of $25,-000 to $50,000 were quoted for *Falcon* Model I. Now it costs about $10,000. Rumor is production runs over 100 a month.



Sidewinder

Infra-red guided *Sidewinder* (AAM-N-7) is one of the Navy's latest aerial weapons and is operationally installed on jet airplanes operating from both land and sea bases. Seen mounted on pylons under the wings, the missile is reported to be one of the most accurate in the business, having successfully knocked flares off the wing tips of an F6F drone without causing sufficient damage or de-

How to be a magnetic tape recording expert

Introducing a useful new brochure on tape in instrumentation

Tape is the stuff of which memories are made – the versatile data memories for a jet propelled age of electronic miracles. If you are one who keeps up with times and techniques, it is a field well worth knowing. This new brochure gives a wide-angle view of the whole subject.

Typical pages

What kinds of applications do you think of when magnetic tape recording is mentioned? Sound recording, of course, and telemetering, if you are in that business. But what about simulating a rough road to test truck axles, controlling a milling machine to cut an aircraft wing section out of a solid billet, monitoring for a sudden occurrence that may happen only once in a year or two, recording data that can be reduced to graphs and tabulations without ever being touched by human hands? These and many more are described.

How significant is the fact that magnetic tape recording reproduces data in the same electrical form in which it was recorded? Enormously important, when you realize all the things the reproduced data can do that couldn't be done with the original signals or with the common forms of visual recording. For example the data can be slowed down to look at fast transients. It can be speeded up for wave analysis. It can be read out in any form. A tabular comparison between original signals and taped signals gives the full story. And a step-by-step pictorial demonstration of magnetic tape recording and reproduction puts the electrical-data idea into tangible, easily visualized form.

What does the data on magnetic tape look like? You can't see it, but the brochure will give you an idea of what it would be like if you could. And incidentally this may help to clarify the differences between various magnetic-tape-recording techniques.

Do you talk in tape's language? When is a tape recorder not a recorder? What is the difference between a channel and a track? What is a servo speed control? A much needed glossary gives the consensus of our views on terms.

For whom did we write this booklet . . . the expert, or the man for whom the whole subject is new? Both. It is written and illustrated so that any engineer or technically trained person can readily grasp the concepts and gain a broad understanding of the subject. If you are one of those who has already worked extensively with tape, you will find some new twists in the way the subject is explained, and perhaps ideas on new areas you hadn't explored. And incidentally, a copy of this brochure in some handy file will give you a good start in indoctrinating that new man in the department.

For your copy, write us today on your company's letterhead. Address your request to Department B-5

The Fairey Fireflash, first British air-to-air guided weapon to destroy radio drone. Two external boost sockets accelerate missile to supersonic speeds. It is a beam rider.

flection to the vehicle to prevent its later recovery.

The infra-red guidance package producing such pin-point accuracy is the first of its type to reach operational status. *Sidewinder* is operational on F9F, F3H-2N and FJ3 aircraft, and sees service with Attack Squadron 46 on the *U.S.S. Randolf* and Fighter Squadron 211 on the *U.S.S. Bonhomme Richard*. It is effective up to 50,000 feet and has an accurate range of about 3500 yards. Contact and ambient fuzes are provided.

Some Navy fighter airplanes carry both radar guided *Sparrows* and infra-red guided *Sidewinders* at the same time. Since infra-red is ineffective in rain or heavy clouds, radar is handy under these conditions. Infra-red is rather difficult to fool, but it can be done.

Bombers, however, can generate powerful interference for radar signals flowing from the intercepter to the missile. Since neither radar nor infra-red is perfect we expect that unguided barrage rockets will form a secondary defense for some time.

Sidewinder is stabilized by attaching small bucket wheels to control surfaces and rotating them at high speed. Performance of *Sidewinder* has attracted the attention of the Air Force which it may mate with the F-104 Lockheed fighter.

The missile is currently delivered by Philco which originally assisted the Naval Ordnance Test Station, China Lake, Calif., in its development. *Sidewinder* is characterized by a blunt nose, four triangular forward fins and four rectangular surfaces aft.

It has been reported that the *Diamond Back* will succeed the *Sidewinder*, and that it, too, will be infra-red guided.

Ding-Dong (MB-1)

Little information has been released on this new, atomic-tipped, liquid propellant, air-to-air missile. Although 1956 is considered the year of its conception, warhead tests were made in the spring of 1955 at the AEC's Nevada test areas to provide basic information on the missile's requirements.

The missile was reportedly flight tested with its A-warhead during the May 1957 AEC atomic firings in Nevada. Developed for the Air Force by Douglas Aircraft Co., it is the first nuclear warhead rocket in the U.S. for air-to-air operations. A solid propellant version is currently reported under development.

Ding-Dong MB-1 (the name *High Card* may once have been used) is to be tested on F-89J, F-102 and F-106 airplanes. The Hughes Aircraft Co. is presumably handling the control problem. Air Force says that it will stock A-warheads for the missile at various points around the country.

The *Tingaling* is a training version of the *Ding-Dong*, with a spotting charge only. Air Defense Command uses it.

A number of air-to-air missile programs were cancelled before they were through the development stage. Navy BuOrd's *Meteor* project, handled by the Massachusetts Institute of Technology, was one of these. Active until 1951, the missile weighed 500 pounds, carried a 25 pound warhead, and was to have flown at Mach 3. Some work on it was reportedly done by the Bell Telephone Laboratories.

The Martin *Oriole* XAAM-N-4 BuAer-sponsored missile program was cancelled in 1954. Little is known about it except that it was to have a range in the neighborhood of ten miles, and was to fly in the Mach 2 region. It may have been ramjet powered.

Among the active programs in the U.S. about which no details are currently available is an air-to-air missile under development by Republic's Guided Missile Division.

Bomber defense missiles are currently receiving considerable attention. It has been widely circulated that Cornell Aeronautical Lab's BDM is merely a modification of the *Hawk* surface-to-air missile. CAL insists, however, that such is not the case, that their missile is a test vehicle specifically designed for bomber defense, and that not only is it completely independent but preceded the *Hawk* design.

The Air Force has long kept an eye on the missile as a possible defen-

Ryan Aeronautical Co. FIREBIRD used radar homing and proximity fuse; was one of first guided air-to-air missiles in U.S. Bottom shot shows MIGHTY MOUSE package on F-86D.

sive weapon for bombers and B-52's may soon be carrying them. This interest probably dated from the time German jet-powered intercepters began to invade American bomber formations in World War II, attacking with 50mm cannon from the rear.

Some investigations were made to adapt 2.25 inch and 5 inch spin-stabilized rockets for such use. To launch rockets from the rear of modern, high speed jet bombers present a series of complex problems including aerodynamics, guidance and control.

One project under study was the 1½ inch caliber *Nasty*, which was given spin stabilization by canted rocket nozzles and canted fins. Its high velocity kept it from weather-vaning when fired sidewise to the rear of bombers. Initial boost was provided by rocket guns, presumably the T-132 known to fire short, 1.5 inch rockets. This North American Aviation development has been cancelled by the Air Force.

Both the *Duck* and *Goose* have been mentioned as missile weapons to be carried by the *Hustler* B-58. Whether either or both have a BDM application is not known.

Air-to-Air Warfare

Air-to-air rocketry requires much in the way of pioneering to develop and maintain invulnerability and accuracy. Weapon and counterweapon have been the order of the day since the earliest battles, and counterweapons from shields and armor to antimissile missiles have always been available to plague the tactician.

The guided air-to-air missile has not yet been tested under real combat conditions. The air-to-air missile is a formidable weapon if only from the viewpoint of the tremendous closure rates to be anticipated from interceptor and attacking intruder, both travelling in the supersonic speed range.

Presumably an optimum air-to-air weapon system must prevail over a maneuvering target and decoys and electronic countermeasures, to say nothing of terrain and weather conditions. The latter are particularly important when the opposing force attacks at low levels.

Prior to combat and without a completely automatic fire-control system, an intercepter has to go through several maneuvers, each susceptible to error. Upon being vectored into position by ground radar through possible cloud cover and chaff countermeasures, the fighter will have to assume the correct heading or collision course, determine the range, speed and maneuverability of the target and get close enough to bring the air-to-air missile into action.

Once launched the missile must follow the path of the attacker and detonate upon or within a lethal distance of the target. This was the picture of events prior to the introduction of a completely automatic fire control system such as that developed by Hughes Aircraft for use with the *Falcon* missile.

Panel removed shows BMD test bomber defense missile's circuitry for control and guidance.

Ideally, ground radar picks up enemy intruders at maximum range and tracks them. Intercepters are sent aloft and homed upon the attacking force by a control system inter-related with the ground radar, a lead collision course being automatically set and flown.

At a pre-set distance the intercepting aircraft's control system takes over, locks on to the attacking force, corrects for intercept and launches the air-to-air missile. The pilot has very little to do with the whole operation.

Countermeasures would appear to be governed by the following factors: Being warned immediately that ground radar is in contact with his aircraft, the attacking pilot will know that defensive intercepters with air-to-air missiles are to be expected within a short while. His immediate reaction might be evasive action such as dispensing chaff and possibly low level operations.

Presumably he would also make preparations to neutralize the anticipated missiles. Such devices as decoys and standard disruption of radar procedures might be used. In the case of the infra-red type guidance, advanced methods of diffusing heat could be used to deflect the missile from the target. A more expensive and complicated device would be the anti-missile missile which is currently being considered for the *Hustler* (B-58) intruder.

Air-to-air missiles are equipped with a variety of warheads each designed for a different purpose. The isotropic warhead or unoriented charge fragments in all directions while the non-isotropic or directional warhead concentrates its power into a single direction. This latter procedure involves a delicate fuze design to determine the whereabouts of the target.

The blast type warhead was conceived as a high pressure device and has an effect similar to that of a depth charge upon a submarine.

There has been some conjecture as to what effect radiation would have on the delivering agent as well as the target.

In defensive action this weapon presumably would be used only over the sea, large open friendly areas or in enemy territory. The thermal warhead, a fire raiser which can be chemical or nuclear or the environmental warhead, designed to put either the crew or propulsion system out of action by a chemical agent of some kind, can be equally lethal.

The selection of a suitable fuze presents quite a problem to the systems engineer as well as the designer. There are many types although the missile and warhead tend to dictate the design of this extremely important component. The timed, proximity and impact fuzes are commonly used.

Since the destruction of a target is intimately coupled with the detonation of the warhead at exactly the right moment, the correct selection of a fuze will be decisive in any attempt to abort an enemy air attack.

Despite the difficulties inherent in the nature of aerial warfare and accentuated in the air-to-air missile system, new and advanced techniques are continually being developed to make the vehicle more efficient and deadly.★

EDISON resistance temperature detectors

provide time constant of less than $\frac{1}{2}$ second

SPECIAL EDISON DESIGN PROVIDES HIGH RATE OF HEAT TRANSFER

An instantaneous response to a change in temperature in monitoring of a guided missile or a motor sleeve bearing could mean the difference of many thousands of dollars in equipment and time. Edison Resistance Temperature Detectors are specifically designed to reduce lag time. Time constants as high as 0.25 seconds have been obtained in special types.

Edison engineers designed these Detectors with rapid heat transfer in mind. The basic element, a low-mass chemically pure nickel or platinum wire, is inherently fast to respond to temperature changes. Couple this fact with such design refinements as using ceramic bushings to cover the fine wire element so that only the tip is exposed to the temperature . . . or providing spring-loaded holders to insure close contact between the detector tip and the surface being measured . . . and flattening the stem, in one instance, so that the heat transfer is more rapid.

These refinements in design are representative of Edison's experience and know-how in temperature control. Other very important features of Edison Resistance Temperature Detectors are elimination of the need for signal amplification, high accuracy and exceptional stability, and hermetically-sealed corrosion-resistant steel wells.

Your need for temperature control means a need for Edison Resistance Temperature Detectors. Write today for complete details. Please state your application.

MODEL 235N90-35
Designed for fast response and high resistance to the corrosive effects of rocket fuels used in guided missiles.
SPECIFICATIONS:
Stem-sensitive.
Useable temperature range —70° to —200°C.
Exponential time constant in agitated waterbath 0.8 second. Maximum hydrostatic pressure on stem: 750 psi at 100°C.
Basic resistance at 0°C = 90 ohms.
Hermetically sealed.

MODEL 242P
This Detector can be operated in live steam or high temperature atmospheres up to 1300°F.
SPECIFICATIONS:
Stem-sensitive.
Useable temperature range —70° to +750°C.
Maximum hydrostatic pressure on stem: 300 psi at 750°C.
Basic resistance at 0°C = 100 ohms.
Hermetically sealed.

MODEL 230N
A general purpose Detector for temperature measurement and control in industrial processes.
SPECIFICATIONS:
Stem-sensitive.
Basic resistance at 0°C = 120 ohms.
Hermetically sealed.

MODEL 166NC
Element is concentrated in tip for sensitivity to surface temperatures in motor bearings, etc.
SPECIFICATIONS:
Tip-sensitive.
Useable temperature range —70° to +300°C.
Basic resistance at 0°C = 120 ohms.

Missile Progress by the Corps of Engineers

By Maj. Gen. David H. Tulley, U.S. Army

Commander, U.S. Army Engineer Center

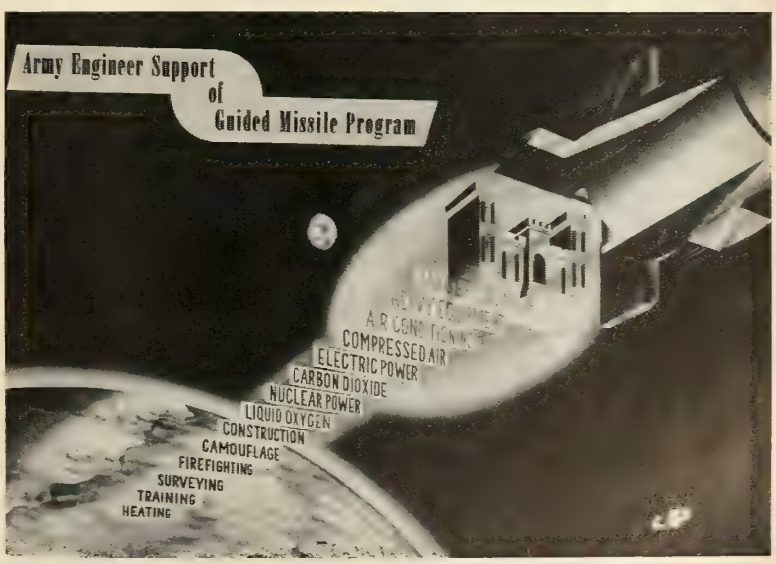
TECHNOLOGICAL and engineering achievement in the missile field has made possible weapon systems of of such potential as to revolutionize our defense organization, tactics and techniques. We find ourselves egging industry on to new accomplishments while scrambling to keep abreast of advances already made.

Pressed by time and the technological advances of others, the Army's Corps of Engineers has been engaged in providing engineering support to the development and testing of the Army guided missile program and the packaged nuclear reactor power program.

Engineering progress in this field is indicated by successful development of such support equipment as the *Nike* ground installation elevator, electrically controlled and hydraulically operated. The elevator brings the missiles from underground storage boxes to above-ground firing positions.

The present *Nike Ajax* elevators are 52 feet long and 9 feet wide; they weigh approximately 12½ tons; the vertical travel is 18 feet. These elevators are being modified to accommodate the larger *Nike Hercules*.

Construction of *Nike* sites is an established mission of the Corps of Engineers. Because of distances imposed by safety regulations, a below-ground site requires only 25 per cent of the real estate area required for above-ground installations.



This advantage represents significant economy in expensive metropolitan real estate. Such construction also necessitates installation and control of heating and air conditioning units.

These units are required in radar control vans to assure greater accuracy and lower maintenance. In addition, it is necessary to provide the missile with a positive fuel feed and high control surface reaction against supersonic pressures. Therefore, high pressure air is required.

This high pressure air must be moisture and dirt free. It is supplied by gasoline-engine powered, multiple stage, 3500 psi air compressors. Another part of the Corps of Engineers' share in ground support equipment is the exacting demand for electrical power for the acquisition radars and guidance systems. These systems require both 60-cycle and a 400-cycle electric power.

In the continental U.S. the Corps of Engineers provides frequency converters to change commercial 60-cycle power to 400-cycle power required by the radar vans; 30, 45, 60, and 150 KW generators for standby and for field use are also provided.

The equipment found at *Nike* sites is maintained by engineer-trained anti-aircraft artillery specialists, backed by engineer field maintenance and depot organizations. The engineer-trained anti-aircraft artillery specialists number 1,200 trained each year at the Engineer School. On completion of training, the soldier specialists report to one of the many *Nike* sites.

Army's Corps of Engineers support of the Army's guided missile program is illustrated in this artist's drawing, showing areas of back-up programs conducted by Belvoir engineers.

Progress to date has been significant. Missile ground support has come a long way and we have learned to establish specifications and design criteria for ground equipment in a short time.

Most significant effort of the Corps of Engineers may well be support of the *Redstone* missile. This support is in the field of liquid oxygen. It is rather difficult to handle under field conditions, is vulnerable to enemy action and boil off losses are high.

The LOX units must be air transportable. Working with other military and civilian agencies, the Corps of Engineers has designed and has in production 5-ton per day, 20-ton per day, and 50-ton per day air-transportable LOX plants.

Firing sites require construction effort on access roads and bridges; thus the need for construction equipment in this ground support phase. In non-tactical areas our military construction program meets the demand for testing installations, laboratories and other missile support activities.

We now provide a 25-ton truck-mounted crane with a 90-foot boom to assemble and raise the missile to the firing attitude from transport position.

Solidified CO_2 is the next item. This generated product is used to cool the *Redstone* guidance mechanism. It is necessary to generate the CO_2 in one plant, solidify it in the other and then saw it into "cocktail" cubes for ease in handling and packing aboard the missile. Anticipated development of better heat-resistant electronic components will make this equipment obsolete. However, its retention with our missile fire fighting equipment is assured.

One of the most challenging problems faced by the Corps of Engineers is target location. The system for locating the target must be compatible with the guidance system for the missile.

Map making has been refined and improved but still requires air or ground control of the area being mapped. After survey, data is compiled and the printing done—two tons of 1/50,000 scale maps or 42,000 sheets will be required to cover the trajectory of one missile.

Actually only two sheets are needed, one for the firing site, the other for the target area. Topographic details between these two are of no consequence but the accurate extension of direction (azimuth), elevation and range from the launching sheet is critically important and is a big problem.

Much effort is presently underway in this problem area and considerable progress has been made. Electronic digital computers have reduced by years the time required for geodetic control adjustment. Theodolites accelerate field survey. Geodimeters and tellurometers measure distances electronically. Radarscope photography maps the ground through clouds and darkness. The earth satellite will help too.

The Corps of Engineers is working on electronic systems to locate photographing aircraft with respect to known terrestrial reference points. Perhaps the answer lies in establishing electronic targets in the sky.

If we can establish such a target and hit it, the ballistic trajectory will take care of the rest. We would then be using an electronic cantilever instead of tons of maps for the preplotted trajectory.

Another subject of interest to the Corps of Engineers because of its association with missile programs, is the subject of nuclear power.

The primary military advantage of nuclear power and heating plants is the potential logistic savings in transporting conventional fuel. As a consequence of this reduced logistic load, military operations are less dependent on long lines of supply and, therefore, less vulnerable to enemy action.

Operations can be more flexible since increases in power may be obtained without too significant increases in logistic effort. More electric power from such sources than heretofore available will substantially affect future planning where large quantities of relatively fuel-free heat are desired. The use of small portable reactors in a given situation could make feasible an operation which might otherwise be marginal.

Recognizing the military advantages of nuclear power plants, the Secretary of Defense assigned to the Army the responsibility for representing the military services in carrying out a research and development program with the Atomic Energy Commission. This responsibility within the Army has been placed on the Chief of Engineers.

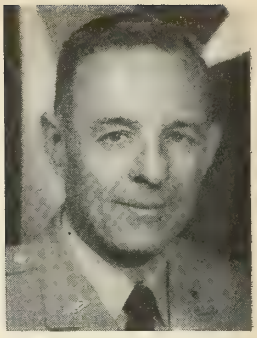
At the present time, a joint Army-AEC program has been established to develop a family of nuclear power plants to meet the requirements of the three services. The plants are to provide power and/or heat in remote inaccessible locations, devastated areas, combat zones and CONUS disaster areas. The large plants will be capable of use in areas where logistical support is difficult, costly, or vulnerable to interruption by enemy action.

Smaller plants could be developed as mobile or semi-mobile compact power plants for support of military operations in theaters of operation and for emergency power requirements. It is contemplated that the mobile plants will be mounted on trailers or barges and that the larger semi-mobile plants will be in the form of air-transportable modules that can be coupled together rapidly in the field of operation and that can readily be moved after operations. Considerable progress has been made in this field. (See article in June 1957 M/R p. 66) ★

Corps of Engineers Support

It takes research scientists and development engineers to design a missile that works on the test range. But it takes the Corps of Engineers to turn it into an operational weapon.

Nearly every phase of missile field support is the responsibility of the Army Engineer. His duties involve use of such things as missile carrying vehicles, fire fighting apparatus, high pressure air compressors, liquid oxygen generation equipment, fuel and liquid oxygen transport trailers and storage containers, camouflage equipment, electric power generators, cranes and other erector equipment.



He is a cornerstone in the ABMA structure.

Out of the cooperatives effort with ABMA has grown a vast research, production and testing network—a far cry from the inadequate facilities that housed ABMA two years ago. Additional facilities are being added as needed.

While he is mainly concerned with this construction program, the Army Engineer's job periphery stretches over a wide area and includes problems of missile logistics, mapping and geodesy, troop support, equipment and supplies, chemical, electrical and mechanical engineering.

A typical day might find him making decisions involving the preparation of plans for new buildings, roads or power plants to giving advice on employment and technical problems or on a new mobile LOX plant.

In addition to its support of ABMA, the Corps of Engineers has also been busy at Redstone Arsenal and White Sands Proving Grounds. It is closely tied to technical services activities. The Corps has assigned representatives to these agencies for consultation and to act as liaison.

Progress in Army Missile Research and Development

By Maj. Gen. August Schomburg, U.S. Army

Assistant Chief of Ordnance for

Research and Development

THE EXTREME requirements for accuracy demand the ultimate from the missile guidance and control engineer. Guidance and control systems present problems which probably surpass any others in the history of military research and development. The guidance and control problem encompasses all items necessary in predicting the missile's flight path, sensing deviations from this path, calculating the kind and amount of corrections needed to return to a new predicted path, translating the corrections into commands, transmitting the commands to the control equipment, translating the commands into necessary control forces, and continuously monitoring the overall functioning.

The problem areas encountered in the design and development of accurate guidance systems for Army missiles are further complicated by tactical requirements.

In the field of surface-to-surface missiles, the Army has a need for a family of field artillery missiles to provide all-weather direct and general support for land, airborne, and amphibious operations. These missiles, carrying appropriate warheads, must accurately extend beyond conventional artillery coverage.

They must also supplement and extend the capabilities of support aircraft. They should provide high accuracy and destructive effectiveness on such targets as tanks and fortifications and furnish supporting fire of required accuracy for combat troops making deep penetrations such as airborne assaults or armored breakthroughs.

The characteristics of enemy weapon systems, missiles as well as aircraft, determine the guidance requirements for anti-air missiles. To be of full value in this atomic age an anti-air missile must have the guidance capability to inactivate a hostile warhead. This puts increasing demands on guidance system designers for greater accuracy capability.

Countermeasure invulnerability is a prime requirement of any effective weapon. The counter-countermeasures design objectives may be stated as designing equipment so that successful countermeasures are technically impossible, tactically not feasible or economically unprofitable.

The design of counter-countermeasures features of Army equipment is undertaken at the very earliest date in the initiation of any new missile project. In order to build a system which will most likely be used five to fifteen years in the future, the designer must consider not only existing and proven countermeasures but must ask himself what can be expected in new countermeasure designs during this period.

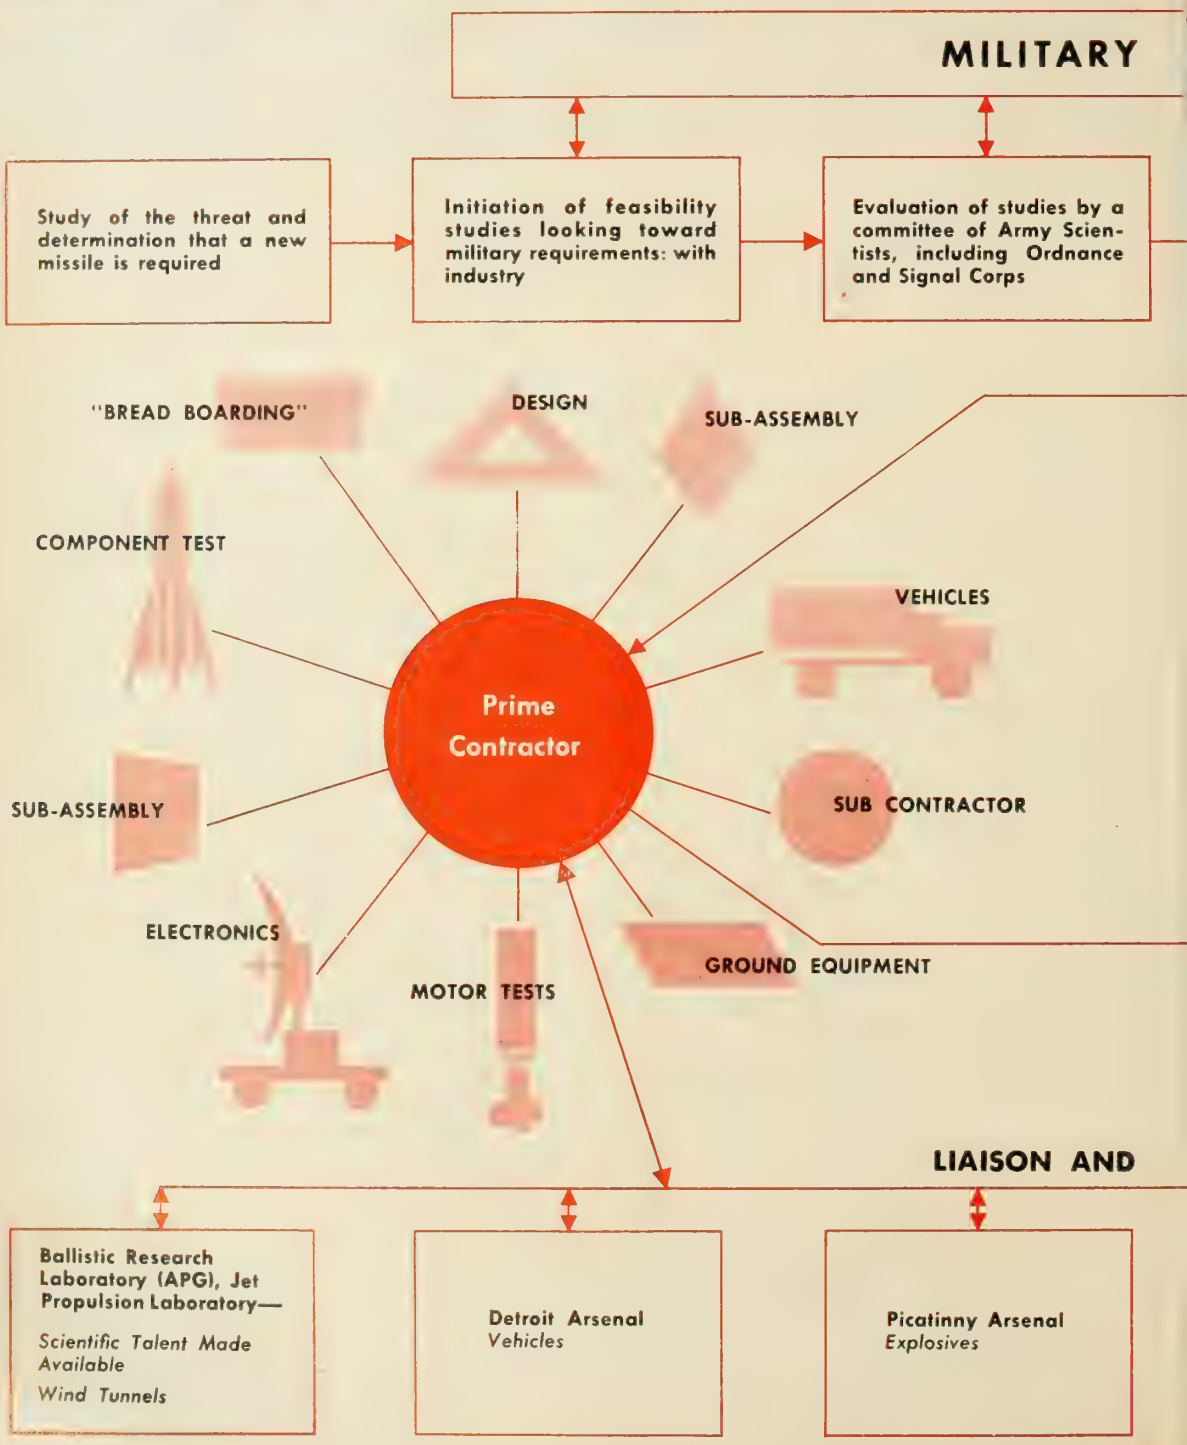
It is important to allow for future system improvements as new components become available. These enable us to produce an effective system on a tight schedule and still take advantage of new techniques at the earliest possible date.

The design must be confirmed after it is established and tested by the designer. Normally, other agencies are engaged to study the design both from theoretical and practical aspects. These studies, which extend to actual and simulated missile flights where countermeasures are used, lead to many design improvements.

While capture is an extreme case, security leaks can be almost as damaging and planning ahead in design can reduce and eliminate the possibility that a system may have to be abandoned because of a counter-measure compromise.

The Army has and will continue to meet and exceed the countermeasure threat by following this procedure: appraising the counter-measure environment, designing accordingly, critically evaluating the design.

Another formidable problem which the weapon system developer must meet is that raised by propulsion. In the early days of missile development liquid rocket propulsion was the only way to obtain the high thrust and the long burning time necessary to meet the high performance requirements of the system. Liquid propulsion motors were used in such successful developments as *Corporal, Nike-Ajax* and *Redstone* missiles.



As time went on research and development agencies of the Army Ordnance Corps established the feasibility of adapting solid propellants to the propulsion problem, based on prior successful experience with free rockets using double base propellants.

At the same time, the agencies indicated that ceilings existed for this type propellant. These ceilings limited performance to such a degree that for certain propulsive requirements, other methods would have to be devised.

The restrictions, however, were not sufficiently stringent to void application to such systems as *Honest John,* the *Nike-Ajax* booster and the currently developmental *Little John.*

Anticipating more demanding applications, the Ordnance Corps research agencies devised a new approach to solid propellant development culminating in the composite family. This major breakthrough opened new opportunities of meeting tactical problems previously

considered beyond solution.

With the use of this tool, systems such as *Lacrosse* and *Dart* have been developed as practical front line weapons able to destroy the enemy's defense network while maintaining a high degree of safety for friendly troops.

New vistas of air defense have also been opened by current developments using these propellants in high performance surface-to-air missiles. Continuous evaluation of enemy attack capabilities and persistent research effort in the field of composite propellants, has made defense against the possible ballistic missile threat a reality from the propulsion viewpoint.

While major advances have been made in the fields of accuracy, countercountermeasures and propulsion, technological advances in aerodynamics, mechanics and aircraft design have followed a parallel course.

Current development programs are using data from the still expanding library of aerodynamic and structural information. Transonic, supersonic, and hypersonic aerodynamic study programs are furnishing data on platform, surface cross-section, over-all configuration, boundary layer conditions and aeroelasticity.

Current research programs in the field of aerodynamic heating at high Mach numbers and controlled motion in rarified air and under vacuum conditions are showing the way to meeting future threats.

It should be emphasized that although the missile itself is a spectacular instrument of destruction, it cannot function alone. Even after guidance, propulsion and ballistics and structures have been perfected, the missile is inert and unless the without the equipment for transporting, preparing, testing and launching. The same painstaking design, testing, redesign, manufacture, and inspection required for an effective weapon must go into every item of ground equipment. Accomplishments are illustrated by the following examples:

Vehicles. In one system now in an advanced stage of development, the number of vehicles required to launch a missile has been reduced by 60%, as compared with the system it supersedes. The corresponding weight reduction is even greater. An even more important result is the reduction of approximately 60% in trained manpower requirements.

Propellant Handling. In several of the older systems, highly corrosive, toxic and inflammable propellants constituted a major problem. In many instances these have been replaced by solid type propellants which require little special equipment and fewer men for handling. This, of course, makes possible a faster rate of assembly and handling, with a corresponding improvement in firing rate.

Launchers. The complexity and reloading time of launching equipment is being reduced. In some instances automatic control is replacing manual operations. Extensive investigations of blast effects and launcher tie-down requirements have been made. These have included tests to determine the most effective deflector configurations and the optimum deflection angle.

Some of the more recent designs of blast deflectors use aluminum to reduce weight. In order to reduce launcher tie-down problems, the reactive forces of the exhaust gases have been employed for launcher stabilization. As a result these problems have been reduced in newer type launchers. Mobility and the time required for placement of some launchers have been improved.

Pre-flight Checkout Equipment. Methods and equipment for pre-flight checkout have also undergone striking improvements. An early missile system required four manhours for missile checkout and many of the checks required a high degree of judgment.

A later system reduced this to three manhours. Another system has reduced this to two-thirds of a manhour and the checks are all of a go, no-go type which require no interpretation by the operator. One recent guided missile only requires one-twentieth of a manhour for checkout.

Target Simulators. Another important achievement in testing equipment is the newer type programmed target simulator. This is a most imporant accomplishment from the standpoint of economy and reliability. With this type tester a series of commands selected to test the missile's performance capabilities can be recorded on a magnetic tape.

These are fed to the missile control system and the responses are recorded. This type of testing can be used to replace much of that formerly done with target drones. In addition to the money saved by eliminating the need for expensive drones and the trained men involved, other very important advantages result.

Drone tests are not repeatable. When a malfunction occurs in a missile flight against a drone, an attempt to duplicate the test may not result in the same malfunction even though the same defect is present. In the tape-controlled test, the commands can be duplicated any number of times.

The testing of missile capabilities must obviously be limited to the ability of existing drones to execute the required maneuvers. Guided missiles must be designed to meet the threat from planes and missiles now under development which will be in the air from four to seven years hence.

The target simulator is the only device available for this type of tests. Also, since the time and money required for this type of test are much less, faster and more complete performance evaluation is possible.

It must be stressed that problems continue to exist and that obsolescence is an ever prevailing specter. But each day under the guidance of the Army weapon systems development agency, the coordinated effort to provide the Army's arsenal with adequate missiles for both offensive and defensive action is continuing apace.

We have made significant progress. The proof is in *Nike-Ajax, Corporal, Honest John*—already in the hands of troops—and in *Nike-Hercules, Hawk, Dart, Lacrosse, Sergeant,* and *Jupiter*—soon to be released. Ground-to-ground, air-to-air, ground-to-air, we have made them all. And they work.★

Rocket Logic in Retrospect

...t the Deacon finished the one-hoss shay.

Now in building of chaises, I tell you what,
There is always *somewhere* a weakest spot,—
In hub, tire, felloe, in spring or thill,
In panel, or crossbar, or floor, or sill,
In screw, bolt, thoroughbrace,—lurking still,
Find it somewhere you must and will,—
Above or below, or within or without,—
And that 's the reason, beyond a doubt,
That a chaise *breaks down*, but does n't *wear out*.

But the Deacon swore (as Deacons do,
With an " I dew vum," or an " I tell *yeou* ")
He would build one shay to beat the taown
'N' the keounty 'n' all the kentry raoun';
It should be so built that it *could n'* break daown:
"Fur," said the Deacon, " 't 's mighty plain
Thut the weakes' place mus' stan' the strain;
'N' the way t' fix it, uz I maintain,
Is only jest
T' make that place uz strong uz the rest."

So the Deacon inquir... the village folk
Where he could find ... oak,
That could n't be sp...

Oliver Wendell Holmes never dreamed of intercontinental missiles or thermal thickets when he penned "The Wonderful One-Hoss Shay". Yet, a hundred years later, no sounder logic exists for the designer of rocket cases. In the ideal rocket design, where a pound less weight can mean miles more distance, all sections should be exactly of identical strength. No part should be one iota stronger or weaker than the rest.

Fulfilling Dr. Holmes' "picture of the impossible" to the ultimate degree has been M. W. Kellogg's aim from the time it began designing and fabricating rocket cases for the Navy Department in 1951. Since then the company has continued to participate in the research, development, and production of a wide range of missile and rocket propulsion systems.

Organizations interested in putting the Kellogg team to work on their specific rocket problems are invited to write.

Upper Air Research Progress . . .

Navy Rockets and the Future of Man

By Rear Admiral Rawson Bennett
Chief of Naval Research

THERE IS ONE unknown that has always been mankind's greatest challenge, and that is the heavens above. Today we simply call it space. We have constantly sought to solve the enigma of heavenly phenomena particularly our own moon, the planet and the stars. And deep within us there has always been the urge to soar through the skies and reach those other worlds.

Soon man will take the first step toward achieving that goal. A man-made sphere will be rocketed 300 miles into the upper atmosphere at a speed of 18,000 miles per hour or nearly five miles per second. This sphere, only 20 inches in diameter, will then circle the earth like a tiny moon while it automatically sends back information to us.

This project is the next logical step forward. The earth satellite heralds a new era in what might be called space research, presaging the day when man himself will venture into outer space.

In 1923, the Naval Research Laboratory was established to carry out broad research in the physical sciences. It is this laboratory, now under ONR management, that is chiefly involved in the development of the earth satellite and launching it into space.

The Office of Naval Research was itself a pioneer organization when it was established in 1946. It was the first military agency specifically designed to support research on a large-scale basis. ONR's chief mission is to finance and promote research by academic and commercial laboratories in virtually every field of science.

Since 1946, ONR's program in upper atmosphere research has been accumulating important scientific data that is achieving both these ends. The knowledge that is being gathered has enabled scientists to gain a better understanding of cosmic-ray activity and very high altitude weather conditions.

If our aircraft are to navigate at heights approaching 100,000 feet at speeds of Mach 5 or more we must have far more accurate information on air density, pressures, and temperatures as well as cosmic radiation at those heights. If we are to achieve any considerable improvement in radio and television communications and long-range electronic detection devices, we must know a great deal more about the ionosphere and magnetic field above the earth which have a controlling effect on radio signals.

The ionosphere is a region of rarified, ionized gas which exists at levels between 50 and 250 miles above the surface of the earth, and our means of studying it from the ground are extremely limited. This complex region of the atmosphere is interrelated with solar activity, geomagnetic disturbances, the aurora, and cosmic rays which are very high-energy-charged particles that come from somewhere in outer space and bombard the earth in all directions.

Each of these phenomena must be studied in relation to the others. For example, magnetic storms that frequently are associated with radio blackouts are connected with sunspots which in some way affect the energy distribution and total flux of cosmic rays.

More precise measurements of the fluctuations in cosmic-ray activity may permit a correlation of these two phenomena. This may ultimately give us the ability to predict periods of poor communication due to solar storms much as weather is predicted today.

The upper atmosphere holds the keys to many of the basic secrets of the universe, yet until the advent of the high-altitude sounding rocket it was like a rolled up scroll that gave us only intriguing peeks and glimpses of its contents.

The first rockets used in upper atmosphere research by the Navy and others were the German V-2's, of which more than a hundred were available after World War II. Most of the V-2's hit altitudes of about 100 miles with one reaching 117 miles.

Convinced by the experience with the V-2 that there were immense possibilities in the use of research rockets, the Navy in 1946 became the first to order rockets specifically designed for upper atmosphere research. That year the Office of Naval Research in close cooperation with the Navy's Bureau of Ordinance ordered the *Aerobee*, which was designed and developed by the Applied Research Laboratory of Johns Hopkins University and the Aerojet-General Corp.

The first full firing was made in November, 1947. Later it was somewhat modified to become the *Aerobee-Hi*. It has been in continuous use longer than any other research rocket and will be one of the chief rockets used in the upper atmosphere experiments of the International Geophysical Year.

Both the *Aerobee* and the *Aerobee-Hi* are much smaller than the V-2 —about 23 and a half feet long and 15 inches in diameter, with the *Aerobee-Hi* generating a thrust of 4,000 pounds. Yet this Navy rocket has been able to travel considerably higher and faster than the V-2, recently reaching a record altitude of higher than 180 miles (possibly 190 miles).

In 1946 ONR's Naval Research Laboratory ordered the large *Viking* research rockets which would be able to carry payloads approaching the 1,000 pounds of the V-2. Developed by The Martin Co., the *Viking* was 48 feet long but reduced to 42 feet in later models. The 14th and last of these rockets was recently fired.

The diameter of the first series was two feet, eight inches, later in-

creased to four feet for the second series. The 8,000 pound fuel load consisted of liquid oxygen and ethyl alcohol, generating a thrust of about 20,000 pounds, far less than the V-2, but the weight of the *Viking* was also considerably under the V-2, ranging from 10,000 to about 16,000 pounds.

The *Viking* rockets, carrying payloads some of which were only 100 or 200 pounds less than the V-2, consistently reached far higher altitudes than the V-2 and in 1954 established the record for single-stage rockets with a height of 158 miles. Although this record has been recently broken by the *Aerobee-Hi*, the payload of the latter rocket is only a few hundred pounds as compared to 825 pounds for the record-breaking *Viking*.

Both the *Aerobee* and the *Aerobee-Hi*, which was first fired in 1952, are "boosted" rockets, in which a JATO-type solid-propellant booster assists the rocket at the start of its flight and then falls away after about three seconds. The fuel is alcohol-aniline and nitric acid which sends the rocket at speed faster than 4,000 mph.

Some of the instruments carried in its nose cone measure the rocket's performance, particularly propulsion, aerodynamics and structure. In recent flights the instruments planned for use in the earth satellite have been carried in a section just below the nose cone.

In one recent flight, instrumentation roughly equivalent to the weight of the satellite included two thermistors for measuring temperatures within the instrument section, a differential pressure gage for comparing internal and external temperatures, three micrometeorite microphones, a solar aspect cell, a Lyman-alpha ion chamber, a satellite Minitrack telemetering transmitter, and the necessary power for the transmitter.

A photoelectric cell was mounted on the side of the rocket to determine the aspect or vertical position of the rocket with respect to the horizon. A solar battery, which weighs considerably less than the mercury-cell battery that will power the transmitter in the first satellites, was also flown to determine its suitability as a power source for the satellite.

Scientific data obtained by the satellite package were telemetered back to earth during the flight via the Minitrack system, while rocket performance data were telemetered by the more conventional *Aerobee* system. The micrometeorite microphones, just as they will on the satellite, detected the sounds of micrometeors or "meteor dust" hitting the skin of the rocket.

One of the phases of the Naval Research Laboratory's rocket research program is high-altitude photography. The first reasonably good high altitude photographs were obtained on a V-2 rocket flight in April, 1947. Little improvement in definition or altitude was achieved until the 1954 record-breaking flight of the eleventh *Viking* previously mentioned.

The 158 miles reached by this rocket is the greatest height from which photographs of the earth have ever been taken. The pictures were made with a 4 x 5-inch K-25 aircraft camera. Sheet-metal housings for the camera were used in the earlier flights but these frequently opened on impact and the film was exposed. Recovery became satisfactory when it was decided to wind the film into a steel casette.

One of the basic problems in rocket research in the upper atmosphere is the expense. The *Aerobee-Hi* rockets, which cost less than the *Viking*, run between $30,000 and $40,000 per rocket. Partly for this reason the Navy has sponsored the development of smaller rockets that are launched from balloons or aircraft.

The balloon-rocket method, known as the *Rockoon*, was developed by Iowa State University. This method combines the 12-foot solid-propellant *Deacon* rocket produced by the Allegheny Ballistics Laboratory with the high-altitude plastic *Skyhook* balloon, which lifts the rocket at a speed of about 800 feet per minute to altitudes generally ranging from 50,000 to 70,000 feet.

At a fixed altitude a pressure switch in the firing gondola closes, setting off the igniter inside the rocket and firing it in an almost vertical direction. The rocket burns for approximately two seconds, but with the aerodynamic drag of the lower altitudes eliminated this is sufficient to send the rocket to altitudes of 50 miles or more.

Another method known as *Rockair* uses aircraft which are sent up to altitudes of 40,000 to 50,000 feet, at which point rockets capable of reaching heights of about 100 miles can be launched.

The nose cone of the *Deacon* rocket contains a small FM transmitter, which telemeters signals from a geiger counter, ionization chamber or pressure and temperature instruments.

The radio signal is received on the ground station where the detector signal is unscrambled from the FM carrier. This signal is then amplified and recorded by a Brush recorder on a moving strip of paper. This makes it possible to determine the cosmic-ray intensity or temperature, pressure and density at any time during the flight.

During the IGY the Navy will play a prominent role in gathering information on the upper atmosphere both through the earth satellite program and through exploration with a number of *Aerobee-Hi* and *Rockoon* and *Rockair* rockets. Most of the *Aerobee-Hi* rockets will be launched from Fort Churchill, Canada, which is on the edge of the northern auroral zone.

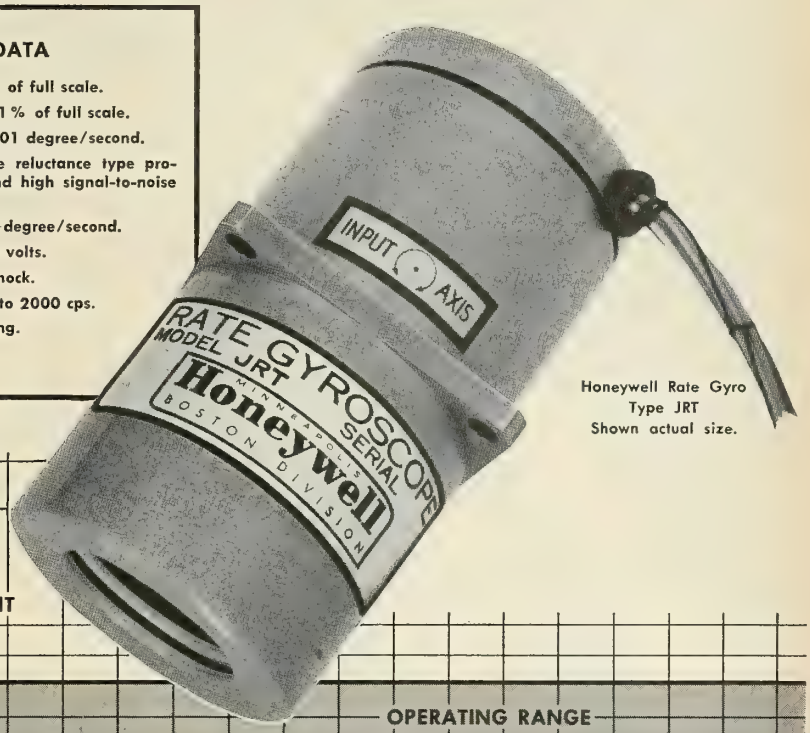
This research will be directed especially to the aurora and to the ionosphere and solar radiations in the auroral zone. The *Rockoon* combinations, to be launched from ships in the Pacific, will be used in getting data on solar ultra-violet and X-ray emissions during solar flares.

There are many unknowns that must be known before we can seriously consider space travel. If the duration of the flight is long, the effects of cosmic and solar radiations on humans must be determined, and we are only beginning to study their effect on living cells. Another risk difficult to assess at present is the probability of meteor collisions.

Although this hazard has been estimated and various schemes proposed for eliminating it, none have ever been tested. In a long flight elaborate equipment requiring a continuous power source will be necessary to provide the human passengers with the necessities of life. This equipment, along with that needed for the navigation of the vehicle, will have to be completely automatic and reliable because the long flight would probably impose terrific physical and psychological strains on the passenger.

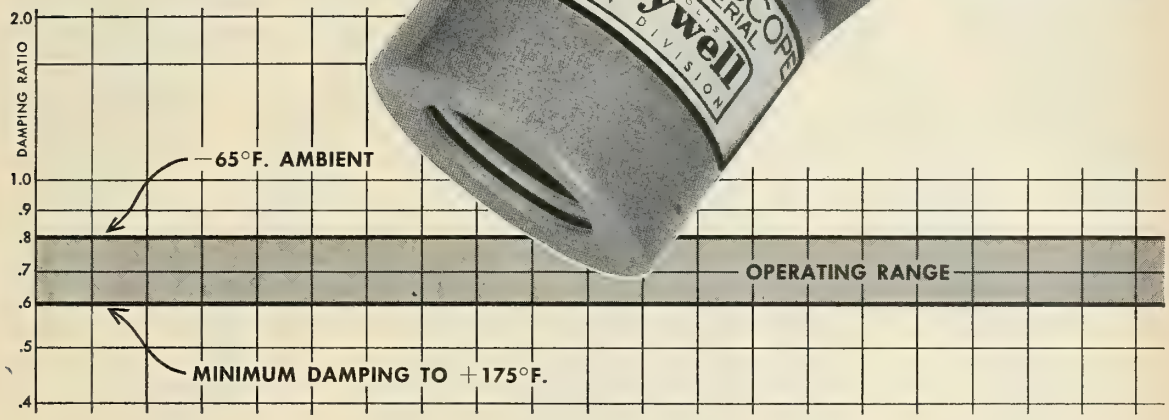
These and other serious obstacles can be overcome only by a relentless program of basic research. We have yet to fully understand the theory of combustion in a rocket motor. We need more research on fuels, on high-temperature metals and ceramics and on new methods for cooling the inner walls of rocket motors and the outer skins of high speed airframes.

The most direct way to attack such problems is through the development of more and better sounding rockets that can ascend far above the altitudes thus far reached. The achievement of practical, reliable, unmanned satellites is also essential.



Rockets and satellites are our best laboratories for space flight research. They are undoubtedly the predecessors of future space ships.

Although space may eventually be a future field of battle, it is a narrow view to consider rocket research as largely military in nature. It would be equally shortsighted to dwell primarily on the material benefits that might be derived from exploring other planets. The one product that makes the entire program justifiable and undeniably worthwhile is knowledge. It is the same product that characterizes all basic research.★



NEW RATE GYRO FOR SEVERE AMBIENT CONDITIONS

DESCRIPTIVE DATA

- **EXCELLENT LINEARITY:** 0.25 % of full scale.
- **LOW HYSTERESIS:** Less than 0.1 % of full scale.
- **LOW THRESHOLD:** Less than 0.01 degree/second.
- **MICROSYN PICKOFF:** Variable reluctance type providing infinite resolution and high signal-to-noise ratio.
- **FULL SCALE RATE:** Up to 1000 degree/second.
- **FULL SCALE OUTPUT:** Up to 12 volts.
- **RUGGED:** Withstands 100 G shock.
- **VIBRATION:** Withstands 15 G to 2000 cps.
- **SIZE:** 2 7/64" diameter 4 5/16" long.
- **WEIGHT:** 2 lbs.

Honeywell Rate Gyro
Type JRT
Shown actual size.

Now! Constant Damping Over Entire Operating Temperature Range

This new HONEYWELL RATE GYRO, Type JRT, is a precision instrument for measurement of absolute rates of rotation in inertial space. Fluid viscosity is electromechanically controlled to maintain a constant damping ratio over the entire operating temperature range of −65°F. to +175°F.

The Type JRT is designed expressly for flight control of long range missiles and flight instrumentation in missiles and aircraft where ambient temperatures are not controlled . . . and at the same time where low threshold, minimum hysteresis, excellent linearity, high natural frequency and ruggedness are essential. Honeywell inertial components and engineering experience are available to assist in the solution of your Gyro system problems. Write for Bulletin JRT . . . Minneapolis-Honeywell, Boston Division, Dept. 45, 1400 Soldiers Field Road, Boston 35, Mass.

Shock wave around a simulated missile at Mach 5.0

SUPERALLOYS for supersonic performance

We develop them. And through modern vacuum melting produce them to the closest possible limits of chemical control and uniformity of mechanical properties for use in such critical components as aircraft turbine blades, buckets and skin material for missiles and rockets. UDIMET 500, one of our well established vacuum melted alloys, combines unsurpassed stress-rupture life with excellent ductility and fatigue strength in the 1200°F to 1800°F range. At 1200°F, for example, its tensile strength is 180,000 psi —at 1600°F, 100,000 psi. For further information concerning applications of these superalloys to your products, write to address below.

VACUUM MELTING
provides these properties

- *High temperature corrosion resistance*
- *Increased ductility*
- *Extreme cleanliness*
- *Precise chemical control*
- *Longer stress-rupture life*
- *Increased tensile strength*
- *Better fatigue resistance*
- *Greater yield strength*
- *Greater impact resistance*
- *Greater creep properties*

UTICA METALS DIVISION OF KELSEY-HAYES

UTICA DROP FORGE & TOOL DIVISION — KELSEY-HAYES CO., UTICA 4, NEW YORK

By Rear Admiral John E. Clark U.S.N.

Director, Guided Missiles Division

Office, Chief of Naval Operations

Navy Missile Progress:

Death of the Big Gun

THE NAVY'S INITIAL missile effort was directed towards basic research. Early work included firing the *Aerobee* and *Viking* rocket series to obtain cosmic radiation data from very high altitudes. Other work tested new ideas and approaches to specific problems such as the feasibility of firing a supersonic missile and controlling it during flight.

One of the earliest missile programs was initiated in 1945 by the Bureau of Ordnance to develop a surface-to-air guided missile. The contract for the research and development of this project was awarded to the Johns Hopkins Applied Physics Laboratory and assigned the now famous code name *Bumblebee.*

The Applied Physics Laboratory was staffed with an outstanding group of scientists and engineers who had done a great deal towards the wartime development of the VT fuze. Their *Bumblebee* program has made great progress and is responsible for the development of all of the Navy's current surface-to-air missiles. Research was also undertaken to develop missiles in the air-to-air, air-to-surface, and surface-to-surface categories.

The *Bat,* an active homing glide bomb, was developed by the Bureau of Ordnance in cooperation with the Bureau of Standards and sank several Japanese ships at the end of World War II. It carried a small radar in the nose which was given a target by the pilot in the mother aircraft prior to launch.

Once launched, the *Bat* homed on its target without further assistance, allowing the aircraft to maneuver as desired. Although successful, *Bat's* short range and slow speed soon put it in the obsolete category.

Another early missile was the *Lark* developed by the Bureau of Aeronautics and Fairchild Aircraft Corp. to prove the feasibility of certain homing techniques. The *Lark* was surface launched and flew at subsonic speeds. It was quite successful and in 1950 knocked down an F6F drone with a direct hit.

This was the first example of what has become an ever-increasing Navy problem, namely that guided missiles have such small miss distances that they frequently splash the expensive drones even without using a warhead.

In the surface-to-surface category, the Bureau of Aeronautics redesigned the German V-1 Buzz Bomb for firing from a submarine, the *USS Cusk.* The *Loon,* as it was called, pioneered a command guidance system, explored the possibilities of pulse-jet propulsion, and gave the Fleet practical experience in developing defenses against guided missile attack. This was also the first time a missile was fired from a submarine by Fleet personnel.

The build up was commenced at such facilities as the Naval Ordnance Test Station, China Lake (Inyokern) Calif.; the Naval Air Missile Test Center, Pt. Mugu, Calif.; the Naval Aviation Ordnance Test Station, Chincoteague, Va.; and the Naval Ordnance Missile Test Facility, White Sands Proving Ground, N.M.

Many now have extensive laboratories and engineering staffs and have made numerous contributions to the solution of such problems as telemetering, flight data reduction, drone control, and miss distance measurement techniques. At least one has been responsible for conceiving and designing an entire new missile system.

For shipboard testing, the Navy converted the 15,000 ton seaplane tender *USS Norton Sound* to handle missiles. To date, she has fired a variety of missiles that would rival the record of any shore facility. These include *Loon, Lark, Aerobee, Viking, Regulus,* and *Terrier.*

Later, in 1952, when the *Terrier* program needed extensive shipboard testing and evaluation, the old 35,000 ton battleship *Mississippi* was given a *Terrier* battery aft. The "Old Miss" has since gone to the scrap pile but before she did the *Terrier* became "the new Fleet weapon."

Early R&D missiles were handmade by scientists and engineers at nearly prohibitive costs. These were R&D missiles and frequently bore little resemblance to the final production weapon. Operability prior to a particular firing was established by a team of scientists and engineers that gave the missile a most rigorous check-out.

The team members were frequently the same personnel who built the bird. These procedures were necessary with the state of the art at the time but out of the question for a service shipboard missile. A great deal of improvement would have to be made in this area. The missiles would have to be reliable and rugged over a tremendous range of service conditions and yet be maintained by relatively untrained enlisted personnel.

Another lesson learned was the advantage of the "weapon system" concept. In this approach responsibility for the entire system's design is vested in one central activity. Coordination of design can be much more closely controlled and the function and importance of a given part can be kept in proper proportion. This is particularly important when a unit is under development and frequent design and production changes are the order of the day.

Related to this approach is the assignment of contractor responsibility. Formerly contracts were let by the technical bureaus for each piece of a system. The complexity of a guided missile system and the necessity of designing each piece to maxi-

High over the Mojave desert, a Sidewinder missile is fired from a Navy jet fighter and streaks through the air for a kill against a target drone. Sidewinder is one of the most potent weapons in current use. Future versions will employ infra-red self-homing guidance.

mize system performance led to the development of two new types of contractual agreements. In one, a designing agency is selected to be responsible for the R&D and basic design.

Other firms are then selected to be the production contractors for the pieces of the system using the basic designs given them. The designing firm remains responsible for the overall system design and coordination but the production contractor is responsible for his hardware.

In the other type of agreement, one contractor is made responsible for system design, coordination and production. He sub-contracts but is still responsible for the finished product. Both techniques have their place and the selection is usually based upon the complexity of the system and the individual capabilities and organizations of the contractors.

Developing a missile from the R&D stage to shipboard service normally starts with a series of test vehicle flights to prove out the basic ideas. When this is completed and the necessary design changes made, a series of prototype missiles are fired. These are hopefully similar to the final product and are the first test of the complete missile system.

Upon successful completion of this phase, a test of the first production pilot line missiles is commenced. This is supposed to work out the bugs so that the production line version is reliable. Lastly, the production line missile is evaluated and released to the Fleet. During this whole time problems arise and have to be solved.

The missile might be exposed to icing conditions in the North Atlantic or to temperatures above 100° in the South Pacific. In one case the wing controls and launcher shoes must be kept operable despite ice formation. In the other, the missile electronics must be able to stand long periods with warm up power applied without overheating from the combined effects of sun and internally generated heat.

The missile must be able to withstand the continuous vibration of a ship yet be so sensitive in flight that it can detect the slightest acceleration. Missiles must be stowed aboard ship so that they are readily available for action but be safe as possible. Fire, shock, battle damage and inadvertant ignition are hazards of the trade.

What do you do, for example, if a rocket engine goes propulsive in a magazine? How do you store a volatile inflammable like av-gas in a submerged submarine full of electrical equipment with sailors who like an occasional smoke? These problems have to be solved before the missile can be accepted for service use.

Another thorny problem area is missile reliability and check-out. How do you produce a missile which has thousands of components yet is always ready to go when you want it? It has been found that one way to lick this is to allow the production contractor to start his production engineering and reliability work as early in the program as possible, preferably in the test vehicle stage. This gives him time to work out the bugs before his designs are finalized.

A good test and maintenance philosophy is required. What components should be tested in the field, how often should they be tested and, if a component fails, what level of repair and replacement should be used? These are extremely important questions affecting not only the missile and the test equipment but such areas as logistics and training as well.

Our present thinking is to have test equipment which tests the missile components known to have a relatively high failure rate or whose function is particularly important. This is a "go-no-go" test and pinpoints a fault only to a replacement level.

Then a package replacement is made and the faulty package is turned in for repair to a depot. The degree to which the package replacement is carried depends upon many factors such as reliability, test equipment simplification, cost and ease of maintenance.

In these days of fantastic budgets missile costs have to be reduced. This problem is attacked across-the-board. Designs are examined for producibility and component economy. Standard "shelf" items are used where performance isn't penalized.

Interchangeability of parts between missiles or components within a missile help to increase production and cut down unit cost. Logistics are thoroughly investigated and planned to increase efficiency and cut costs.

Missile transportation from factory to dockside has to be worked out carefully. The possibility of high explosives detonating in public transportation has to be minimized, yet speed of delivery is important. Missiles in transit are unavailable and this effectively means buying more missiles. Will the missile fit in the conveyor, can it be handled by the equipment available at the transfer points, will handling damage the missile? These and other questions must be answered.

Consideration must be given to the training of personnel so that at the time of a missile release adequately trained personnel are available. To do this schools and courses are set up, usually during the final stages of the missile R&D. Sometimes courses are conducted at one of the Navy's training centers such as the Fleet Air Defense Training Center at Dam Neck, Virginia.

In other situations a school may be set up right at the contractor's plant. Naval "Guided Missile Units" are set up to assist in the R&D flight testing and provide a trained manpower pool for future expansion. GMU-21, for example, did the shipboard testing of *Terrier* in the *USS Mississippi* and then provided a nucleus of trained personnel for the first missile cruisers, *USS Boston* and *USS Canberra.*

The Bluejackets have now taken over from the scientists and engineers and missiles are handled aboard ship entirely by Naval personnel. Reliability has improved if anything and the Bluejackets have shown that they are fully capable of maintaining and operating their new weapons.

These are a few of the problems along the road of developing service guided missiles.★

Progress in Air Force Scientific Research

By Brig. Gen. Hollingsworth F. Gregory, USAF
Commander, Office of Scientific Research (ARDC)

ALL STRATEGIC and tactical military planning is evolved from an "estimate of the situation." This can be prepared only on the basis of the most complete knowledge possible of friendly and enemy weapon capabilities and the factors of personnel, material, communications, terrain and weather. The fighting man puts weapon capability, terrain and weather at the top of his estimate.

It is important for the airman to have full knowledge of his theater of operations—the atmosphere and the space around it—as it is for the infantry to know the surface of the earth. He must be acquainted with every aspect of the atmosphere or space, its environment, our own and the potential enemy's capabilities. This includes vehicles, weapon systems and closely related human factors.

We must adapt the old infantry rule to the aerial dimension: "Take the high ground."

Elevation is as important to the airman as it has ever been to the rifle-bearing soldier. There is no aspect of space which can be ignored if we are to obtain intelligence essential for domination of this future theater of operations.

The weapons and vehicles of this theater demand an exploratory effort equal to that of the new environment itself. Exploration is of value only as its findings are correctly interpreted and usefully related to solving the military problems at hand.

The mission of the Air Force Office of Scientific Research, an agency of the Air Research and Development Command, is the encouragement of exploratory effort, the understanding of its results and the utilization of its findings for the present and future needs of the Air Force. AFOSR's contribution to the estimate of our present defense situation and future potential helps the Air Force maintain a dominant position on the "high ground."

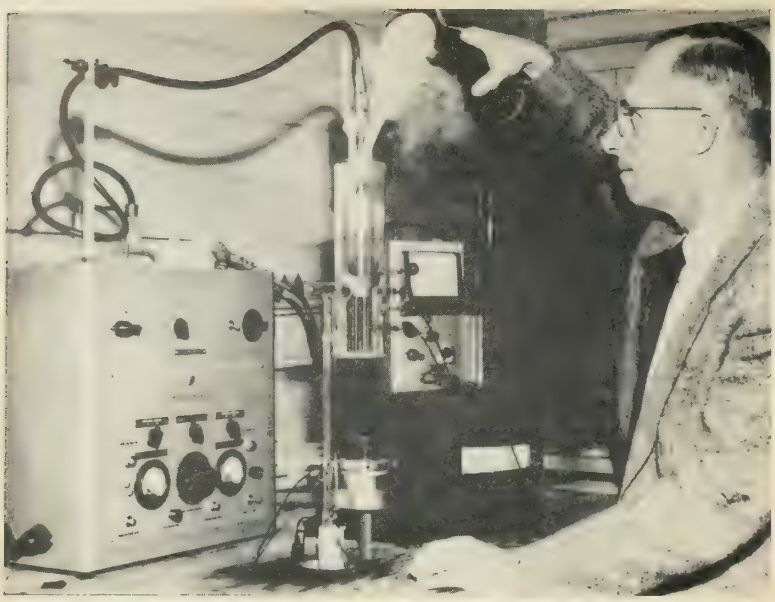
Our method of operation includes making our mission known to research sources, examining their lines of investigation and providing whatever support and guidance they may need.

To accomplish this we seek help from our academic and industrial laboratories. AFOSR and its military and civilian personnel are charged with the sole task of recognizing the military implications of this work and supporting with funds, tools, procurement methods and communication, those persons who can supply us with the essential ingredients for our changing estimate of the situation.

Materials are our initial problem. Recent breakthroughs in propulsion technology have presented us with rigorous new parameters imposed by higher altitudes, the thermal barrier, accelerated corrosion, protection from radiation and stresses due to ever-increasing performance requirements.

An AFOSR-sponsored study with great promise is under way at the Institute of Engineering Research of the University of California. Because upper temperature limits of commercially available metals are approximately 1700°F., investigators at this university proposed a study to improve the ductility of refractory ceramics.

Stimulated by Joffee's disclosure in 1924 that normally brittle crystals of sodium chloride become ductile and deformed when immersed in warm water, the investigators recently attempted similar work with crystals of potassium chloride and silver chloride. These investigations showed promise and have received our support.



The cost of this program is less than that of three conventional 2½-ton military trucks. AFOSR's recognition of its implications may save countless millions in future airframe and powerplant development.

Our future fighting vehicle undoubtedly will traverse the highest regions of the atmosphere, where it will be subjected to constant bombardment by intense ultraviolet radiation. Knowledge of the reaction of light metal shells to this radiation is important. Recognition of this stimulated AFOSR's interest in the work of Drs. H. Margenau at Yale and B. Henke at Pomona College. They are both investigating the absorbtivity and emissivity of metals over the wave length of 10 to 1000 angstrom units.

The reaction of light metal shells to the extreme ultraviolet and soft x-ray regions is a special area of AFOSR interest. Incident radiation is an important factor governing the equilibrium of missile skin temperature. Indications are that certain light metals and alloys, by exposure to selected wavelengths, may give enhanced absorption properties.

Many materials for Air Force application may evolve from studies under way at the University of Florida. A group under Dr. George E. Butler is tracking down new methods and answers to the problems of polymerization. Substituting silicon, phosphorus, selenium, germanium, zinc, or sulphur for nitrogen in allyl-derived polymer may yield new high-temperature materials. Among these are nonflammable lubricants, antioxidants, and new types of oil-resistant synthetic rubber.

When metal foil is bombarded on one side by positive ions, it ejects metallic atoms from the other side. This phenomenon, discovered by Dr. L. G. Parratt of Cornell University under an AFOSR contract, may provide

Dr. Erwin W. Muller, Pennsylvania State University Physics Professor pours the cooling agent into his field ion emission microscope for photographing single atoms.

new methods of mass spectrometry which will greatly enhance techniques employed in the analysis of solids.

The work described here is a very small representation of AFOSR's total effort in this area. The importance of this knowledge to a valid estimate of our technological situation cannot be stressed too heavily.

The performance of a vehicle and its potency are largely governed by its propulsion system. Many AFOSR contracts aim for a major breakthrough in this field.

Since the early development of liquid-fuel rockets, extensive research effort has been devoted to the evaluation of various fuel and oxidizer combinations BMW (Bavarischen Motor Werke), for example, evaluated some 3,000 fuel-oxidizer combinations for the Germans during the Second World War. AFOSR contractors are studying conventional fuels, and hoping to obtain a better understanding of the combustion process.

AFOSR work in propulsion involves many vital areas of investigation. Three can be mentioned here: studies of ultra-energy fuels, solid propellants and flame speeds. The problem of propelling vehicles longer distances at higher altitudes involves fuels with higher specific impulse than current, conventional, chemical compounds.

Aerojet General Corp., under AFOSR contract, is investigating the use of free radicals and atoms to augment burning rate and thrust. It has been discovered that stable molecular particles can be made to dissociate into free radicals if enough energy is introduced from an external source to break their chemical bond.

When the recombination of these particles occurs, the energy release is tremendous. The bulk of U.S. free-radical research is now being carried out at the National Bureau of Standards under a tri-service contract. However, AFOSR had sponsored some of the initial investigation in this field.

Studies of flame speeds must necessarily accompany investigation of propulsion methods. AFOSR has a number of contracts involving flame speeds. The fact that turbulent flames have higher speeds than laminar flames has been established, but as yet attempts to correlate speed with the intensity of the turbulence have been only partially successful.

Research efforts at the Bureau of Mines have disclosed an important anomaly: Indications are that turbulence intensity accounts for the increased flame speed at Reynolds Numbers of 50,000 to 100,000, but not for increased speed at lower numbers.

Investigation disclosed that flame speeds had a maximum value close to 25,000 rather than an increased speed in direct proportion to the increase in intensity. Flame-speed studies are becoming increasingly important as attempts are made to achieve better yardsticks for the measurement of the combustion processes.

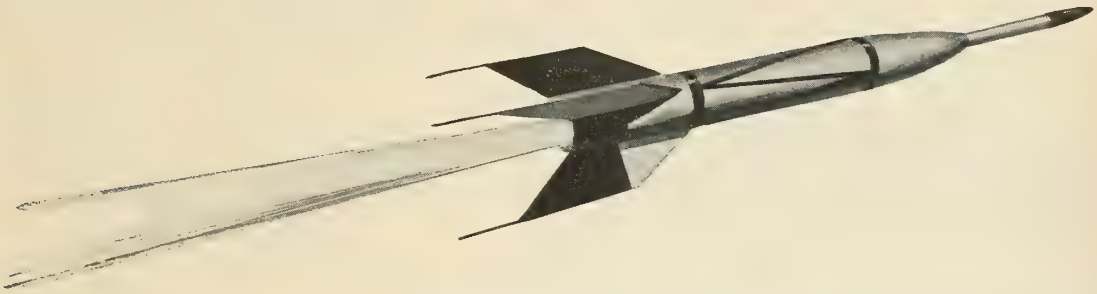
Research has given us two new devices which have application as spectrometers, amplifiers, or oscillators. They were by-products of recent molecular and nuclear investigations sponsored jointly by AFOSR, the Office of Naval Research, and the Signal Corps Engineering Laboratory, and are known as the solid-state maser and gas maser. (Maser is short for microwave amplification by stimulated emission of radiation.)

These devices have military applicability almost as widespread as that of the transistor, but they will not compete with the transistor in use. The solid-state maser may give us (1) a low-noise variable microwave amplifier, (2) an extremely sensitive device for long-range radar detection, (3) better components for a long-range celestial navigation device, and (4) more accurate missile-guidance and weapon-firing systems.

The gas maser promises to yield extremely accurate frequency standards which means an accurate clock for use in electronic navigation and guidance systems. In addition it will make possible a better device for reducing data obtained by use of photoelectric cells.

The principle of the solid-state maser was evolved by Dr. N. Bloembergen at Harvard University. Hycon Eastern is now applying it to some of its weapons-development programs. The gas maser was brought about by the work of Dr. C. H. Townes at Columbia University. It is currently being applied to the development of improved long-range navigation systems by Rome Air Development Center.

A project promising considerable new information about the ionization density in far outer atmosphere and the way in which very low frequency electromagnetic waves are propagated at some 20,000 miles above the earth is now underway. Dr. R. A. Hellwell is investigating the "whistler" mode of propagation, at Stanford University under AFOSR contract.



The "whistler" is an atmospheric disturbance in the audio-frequency range resulting from lightning discharge. If sufficient ionization is present some of the energy of the discharge will be guided along a line of the earth's magnetic field through the ionosphere and far into space, returning to the earth as a dispersed wave train at the other end of the magnetic field line.

It has been demonstrated by the transmission of manmade signals between Annapolis and Cape Horn (approximate conjugate points of an earth's magnetic field line), that the "whistler" mode of propagation is real and can be used for communication and guidance systems. This research may uncover new possibilities for vehicles traveling far out from earth.

The "whistler" also offers a new "probe" into the properties of the outer atmosphere, notably the variation of

WHERE YOU WANT IT...

A DEPENDABLE SOURCE OF AUXILIARY POWER

A leader in the development of reliable, light-weight, self-contained monofuel auxiliary power systems for guided missiles and piloted high performance aircraft, Kidde now offers its combined engineering talents and precision manufacturing resources to firms interested in advanced applications of auxiliary power systems.

At present, Kidde has available turbine-driven units with horsepower of up to 200. These high speed units are designed to supply accurately regulated power at mean altitudes of 40,000 feet and up. However, they may easily be made environment-free, permitting airframe builders extremely wide latitude in systems design.

As a part of its power system development program, Kidde has gained wide experience with many monopropellants. These include ethylene oxide, hydrazine, hydrogen peroxide and propyl nitrate.

Whatever your present or future auxiliary power requirements, Kidde is ready to develop, test and manufacture equipment which will meet your exact specifications. For full information, write Kidde today.

from FLEXONICS

. . . a full line of ducting and flexible assemblies for the Aircraft Industry

1. FLEXON® METAL HOSE, corrosion resistant steel, is manufactured in the broadest varieties of size and types for all aircraft applications. Standard or special fittings available.

2. FLEX-O-TUBE® RUBBER and TEFLON* HOSE is offered in a wide range of types and sizes for handling liquids and gases to Mil specs, for use where applicable. Can be furnished with standard or special fittings.

3. FLEXON® FLEXIBLE CONNECTORS in corrosion resistant alloys are made in a complete range of sizes and types including pinned elbow and gimbal joints.

4. FLEXON® DUCTING, standard or high strength corrosion resistant steel is available in a complete range of sizes and shapes with or without integral insulation. Minimum weight is a notable feature.

5. FLEXON® BELLOWS are made in an almost unlimited range of sizes and types to meet the most advanced aircraft requirements.

• Every Flexonics aircraft component is designed with maximum safety consideration, engineered with skill and produced with manufacturing know-how that comes only with long practical experience. Since the ultimate success of your project can be influenced by components such as these . . . bring your most challenging problems to Flexonics, where years ahead things are happening.

The newly prepared Flexonics Aircraft Engineering Manual is available to qualified persons. Write for information on how to secure a copy.

ambient ionization density with distance and the existence of the "ring current" which should be found between 25,000 and 35,000 miles from the earth.

This research will provide information on ionospheric irregularities, velocities of solar streams entering the atmosphere and perturbation of the earth's magnetic field, thus providing a better theoretical interpretation of magnetic storms and aurorae, both of which strongly affect communication and guidance.

Obtaining accurate estimates of future propulsion, materials and guidance and communications characteristics of our future weapon implies a complete study of its aerodynamic characteristics. To gain this knowledge, AFOSR is sponsoring work of great importance in rarefied gas dynamics.

In addition to the results of the basic work in this field, much has been developed in new equipment for better study and understanding of related problems.

A major breakthrough occurred under an AFOSR contract with the Cornell Aeronautical Laboratory. This was development of a shock tube, a facility for realistic testing of configurations in an air-flow of 10,000 mph and at temperatures of 9000°F for longer periods of time than previously had been possible.

This facility incorporates a "wave superheater," a new departure which increases the length of time an object in the tube is exposed to the heat and pressure of the shock wave. This factor of prolonged exposure permits more sustained and closer observation of the effects of heat and hypersonic flow around objects placed in the tube.

Further valuable knowledge concerning the field of high temperature will be forthcoming as a result of the record-breaking achievements of Dr. A. V. Grosse, at the Research Institute of Temple University, in Philadelphia.

Dr. Grosse's group, working under an AFOSR contract, has succeeded in mixing cyanogen and oxygen to achieve a temperature of 4500°C. By mixing carbon subnitride and oxygen, this group has attained a temperature of 5000°C. Dr. Grosse and his staff have also produced a flame from pure ozone.

With the exception of a small region near the nose, modern high-performance aircraft flying at high speeds are confronted with boundary-layer turbulence. Results of an AFOSR-sponsored study of the interaction of shock waves with turbulent boundary layers have been applied to design of better diffusers, closer predictions of control effectiveness, predictions of separation on supersonic wings and bodies and improved design criteria for the flow passages in supersonic compressors. The past year's work has resulted in the first complete series of tests covering a range of Mach numbers 1 to 4.

Further work toward defining the laws of aerodynamics is sponsored jointly by AFOSR and ONR at the University of Southern California. Results of this work now indicate that skin friction is a much higher factor than existing theories had indicated.

An estimate of the capabilities of our space weapon system would be hopelessly inadequate if we were to ignore the human factors involved. If our vehicle is man-carrying, it must be maintained by men who must be selected, trained and motivated to utilize our system to full advantage in combat.

Whether temporary oxygen deprivation produces reversible or irreversible changes in living tissue is knowledge essential to man's safe existence in a synthetic environment. The Pharmacological Institute of Heidelberg University, sponsored by AFOSR under contract to ARDC's European Office, is investigating this area.

In studying the biochemical changes in brain tissue under low oxygen conditions, attention was concentrated on the phosphate esters which are important in metabolism.

Preliminary experiments on human red blood cells revealed for the first time that anoxia does not change their energy-rich phosphate content. Studies of brain changes produced different results.

Techniques developed by these investigations now make it possible to document all changes in the important compounds in brain tissue whether caused by lack of oxygen or drugs. Research is under way to determine if available chemicals will increase resistance to these damaging effects of oxygen lack.

The Astronautics Symposium held at San Diego last February by AFOSR and the Convair Division of General Dynamics Corp. highlighted the interest and rapid advance in the science of flight.

More than 60 scientists gave papers on various aspects of astronautics, covering such areas as re-entry, tracking and communications, environment and measurements, propulsion, orbits and human factors. The open sessions were followed by a one-day classified session which was highlighted by a talk on "The Military Requirements for Manned Space Vehicles" by Colonel W. O. Davis, AFOSR Deputy Commander for Operations. Over 550 clearances were obtained for this session.

Total symposium registration was over 700. All major press, radio, and television organizations were represented, and the meeting received excellent coverage by all media.

It is clearly recognized today that military success is born of plans conceived by what is known as the indirect strategic concept. Direct strategic concepts are those plans which are evolved primarily to offset known enemy capabilities or intentions.

The indirect approach is predicted on plans evolved from complete knowledge, understanding, and application of our own techniques and weapons, largely independent of hostile influences to our thinking. The few examples of research work mentioned here are a random selection from the more than 600 basic research contracts supported at this time by the AFOSR.★

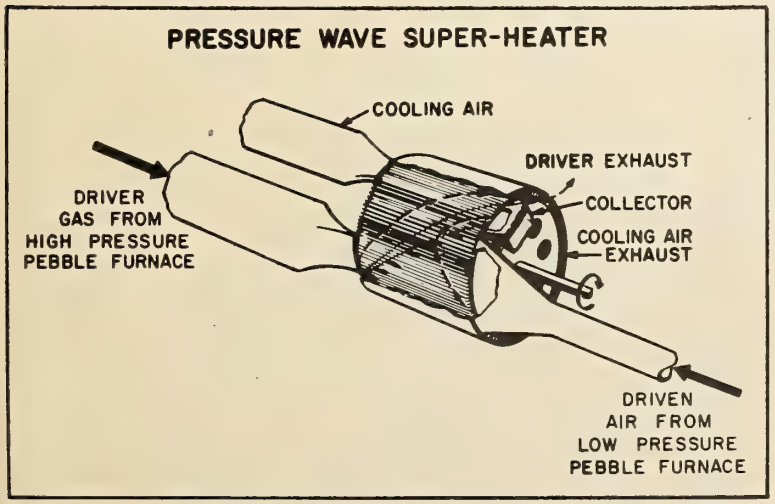

Diagram of a pressure wave super-heater such as that employed to extend the period of test conditions in a shock tube. This is typical of AFOSR-supported research programs.

TECHNIQUES and DEVELOPMENTS
in oscillographic recording

FROM
SANBORN

DESIGN PRINCIPLES AND SOME APPLICATIONS OF A PREAMPLIFIER FOR LOGARITHMIC MEASUREMENTS

THE Model 150-1400 Log Audio Preamplifier (Figure 1), one of eleven plug-in "front ends" now available for 150 Series systems, permits measurements involving logarithmic or exponential functions. The "Log Diode" circuit (shaded portion of circuit block diagram in Fig. 2) is the heart of this instrument, and is based on the logarithmic relationship between the voltage across a thermionic diode and the current through it. If R is large, the current through the diode i_1 becomes proportional to the voltage e_1, and the logarithmic relationship of e_2 and i_1 is transformed into a logarithmic relationship between e_2 and e_1. Circuit constants for this Preamp were chosen to provide an accurately logarithmic relationship between e_2 and e_1, over the range of 200 to .63 volts for e_1. This is a 50 db spread, and the gain of the DC output amplifier (fed by e_2) is arranged so that a 50 db variation in e_1 produces a 50 mm stylus deflection.

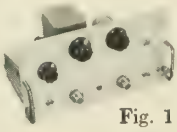

Fig. 1

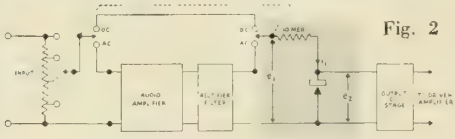

Fig. 2

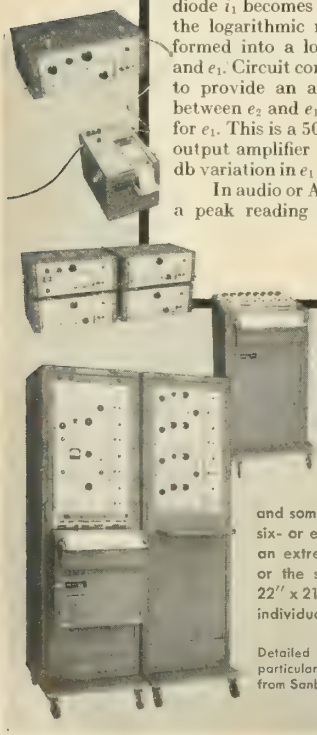

In audio or AC measurements, e_1 is derived from a peak reading type rectifier-filter circuit, which follows a high quality 20 cycle — 20 KC audio amplifier. With an input of 100 mv RMS, this amplifier will produce a 200 volt output from the rectifier. The 50 db chart, therefore, corresponds to a variation in AC input voltage of 0.316 to 100 mv.

In DC measurements, the audio amplifier is bypassed and the input applied to the diode circuit. Since the diode itself is a rectifier, used in the forward direction with its cathode near ground, the DC input must be polarized with the high side positive.

One broad area of application for the Log Audio preamplifier is audio level recording. For example, room reverberation time can be measured by recording sound level decay after the sound source is suddenly turned off, the reverberation time considered the period required for a 60 db decay to occur. Another example of audio signal recording is the plotting of frequency response curves of audio equipment such as microphones, filters, loudspeakers, etc. A multi-channel recording system with appropriate filters also makes possible audio spectrum analysis.

A second major type of application of this Preamp is the recording of DC voltages on a db basis. If the signals are small, a chopper can be used to convert DC to AC, thus taking advantage of the Preamplifier's audio amplifier. With an impedance matching transformer added to such an arrangement, the system becomes a logarithmic DC millivoltmeter or logarithmic DC microammeter of extreme sensitivity. Such a device could be used for plotting the volt-ampere characteristic of a germanium diode, which might be very helpful in selecting matched pairs of diodes. Another possibility is plotting the output of a fixed gain radio receiver and linear detector to a db scale, to rapidly record antenna performance data.

A comprehensive discussion of the design and these applications of the Log Audio Preamplifier is contained in an article by Dr. Arthur Miller, Chief Electrical Engineer of Sanborn Company, published in the Sanborn RIGHT ANGLE. Copies are available on request.

Which Oscillographic Recording "PACKAGE" fits your needs?

SANBORN "150's" are housed, basically, in either of two ways: a vertical mobile cabinet, or separate portable cases for amplifier and recorder units. This in itself provides a number of "packaging" possibilities, but the number is greatly increased by various other alternate, and sometimes special, housings. For example, an entire six- or eight-channel recording assembly is available in an extremely compact, mobile cabinet only 45" high; or the same recorder can be portably housed in a 22" x 21" x 23" case. If field use of "150's" is planned, individual units in cases fitted with removable covers and carrying handles, connected by patch cords, may be the best answer. Occasionally only a "special" adaption will meet a specific need.

But *whatever* the "150" oscillographic recording "package" you use, you're assured of basic Sanborn "150" advantages: *inkless* recordings in *true* rectangular coordinates; *1% linearity*, resulting from high torque galvanometers and current-feedback driver amplifiers; *numerous chart speeds*, from 0.25 to 100 mm/sec.; choice of *single to 8-channel* systems, readily adapted to new requirements by plug-in Preamplifiers selected from *11* presently available types.

Detailed information, and assistance with your particular recording problem, is always available from Sanborn engineers.

Propulsion Engineering

By Alfred J. Zaehringer

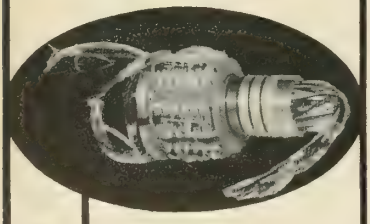
RESEARCH LABS OF TWO FIRMS engaged in the high energy fuel program are in for expansion. Olin Mathieson (Buffalo, N. Y.) has a new research lab for defense work. Stauffer Chemical Co. (Richmond, Calif.) is spending several hundred thousand dollars in a major lab addition. American Potash & Chemical is now turning out decaborane at its Henderson, Nev. pilot plant. Capacity: 1 lb/day. Cost: $600-800/lb. Eventual cost under $100/lb.

BORON SPECIALTIES will be produced at a second Callery Chemical plant at Lawrence, Kan. Operational by 1958, the plant will cost some $3-4 million . . . React triethylaluminum, aluminum, and hydrogen at 300 atmospheres pressure and you wind up with ethylaluminum hydride. Ethyl Corp. has made the material which may pay its way as a boron-production intermediate, a fuel, or a fuel-igniter . . . An organic system for production of hydrogen peroxide from anthraquinone has been patented (US 2,791,491) by the English Laporte Chemicals Limited . . . Purdue Research Foundation is working on the production of alpha nitroesters. Propellant use is seen.

FRENCH SEPR FIRM has come up with a line of igniters for non-hypergolic rocket propellants. They use organometallics which ignite on contact with an oxygen-containing oxidant. Materials named are: diethyl aluminum bromide, dimethyl aluminum bromide, ethyl aluminum iodobromide, methyl zinc iodide, and methyl aluminum di-iodide . . . Meanwhile, SNCASE reports that it is using dichromates or permanganates as catalysts in nitric acid oxidant systems. The fuels—mixed amines—as catalyzed with 0.1-5% of iron carbonyl.

HOW MUCH ETHYLENE OXIDE (ETO) is being used as a propellant? US ETO capacity is over ½ million tons/year. Estimates tag propulsion uses at about 10-100 tons/year. At current market prices, this would represent an upper chemical market of about $30,000-$50,000/year. Virtually all ETO goes into APU's for the IRBM and ICBM program.

AMMONIUM PERCHLORATE, smokeless oxidant for composite solid propellants, is now being made on a continuous basis. American Potash & Chemical Co., Henderson, Nev., is turning out about 10 tons/day at the Navy-owned plant. Capacity is 40 tons/day. Since this is the only large-scale US production facility, ammonium perchlorate solid propellants are being produced at the 10-14 tons/day level.



NEW SOLID PROPELLANT gas generating composition: 55-75% ammonium nitrate, 25-45% calcium formate, and ½% calcium stearate. Imperial Chemical Industries developed this pressed charge. The firm has also studied the combustion of methane with oxygen. A CH_4:0_2 ratio of 2:1 gives the most reactive condition, 1:1 is easiest to detonate, while 1:2 was the most flammable . . . Other new solid propellants were patented by Aerojet. One smokeless composite uses trinitrocyclohexylamine (85%) with beeswax (15%). Ammonium perchlorate (50%) and TNT (25%) are used in other propellants using thermoplastic fuel-binders (viz., asphalt-oil) (25%).

CHALK UP ANOTHER COMMERCIAL APPLICATION for solid propellants. NRL has developed a fire extinguisher for use at polar temperatures (to —75°F.). A standard 2½ gal. extinguisher has a head fitted with a nitroguanidine-guanidine nitrate cartridge. The propelling charge gives a 10% increase in extinguisher capacity . . . More lithium compounds for solids are shaping up. American Potash & Chemical is now producing two lithium oxidants—the nitrate and the perchlorate. The latter promises to give the most oxygen per pound of any stable, inorganic compound.

Astrionics

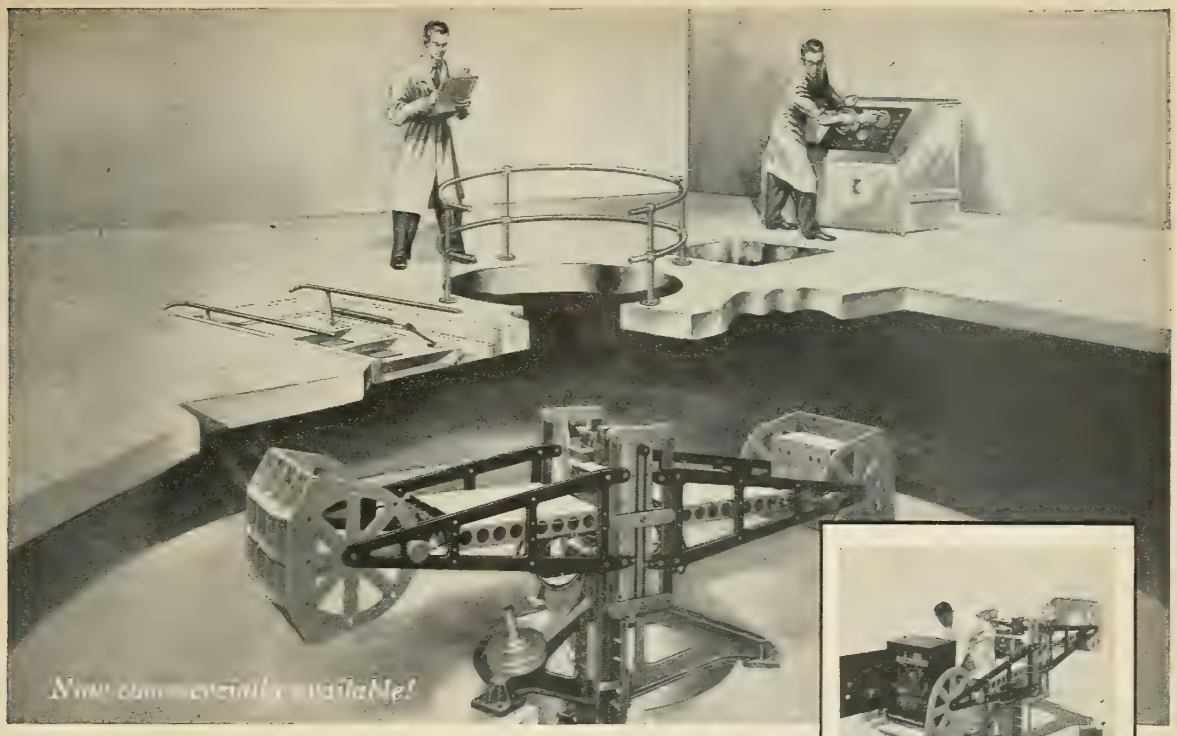
By Henry P. Steier

Air Force countermeasures equipment requirements for fiscal 1957 was $113.3-million. In 1958 it was considerably more. Total $207.3-million. There's lots of room and an especially critical need for advances in this field. Electronics countermeasures techniques used by U.S. are a well kept secret. It's no secret that traveling wave tubes and other wide-band generators are at the heart of the equipment. In the light of Russian radar advances we're falling behind in finding ways to foil their radar. More power and bandwidth are needed.

Superconductivity may give us new jamming capability. Federal Telecommunication Laboratories reports it is applying superconductivity to an Air Force countermeasures problem. Superconductivity causes a metal's electrical resistance to drop to near zero and involves use of very low temperatures such as the 452.2 degrees F used by FTL. This is near absolute zero temperature and sounds like an excellent way to boost radio frequency efficiency in a traveling wave tube, and thus get great gains in power.

Infra-red countermeasures are likely to crop-up soon. *Sidewinder* missile is said to zip right up the tail pipe of a jet plane because its IR sensing cell looks for the highest intensity IR source. Similar, but "hotter" IR-spots might be created by countermeasures flares using a variation of the old thermite incendiary bombs to create the right kind of infra-red source.

•



Transducers for missiles are big business. Retirement fund investors apparently think its a stable business. General Electric, U.S. Steel, Bethlehem Steel and Yale University were reported to have invested heavily in Gulton Industries, Inc. recently. Gulton's products are used by every engine, aircraft and missile maker. Important products are accelerometers, pressure gauges, pressure switches, thermistors, ultrasonic equipment, etc. A key material in these is barium titanate which has piezo-electric properties and high temperature capability. They make instruments that work to 800° C. Gulton just sold Convair $1.6-million worth of accelerometer systems for *Atlas* missile project. Devices that fit in palm of the hand cost $900 and have wide sensitivity from ½ to 1000g in one unit. Barium titanate is becoming a critical defense item. Supplied solely by one outfit, Titanium Alloy Metals, Buffalo, N. Y., the material's purity control is a key factor in its application. Even so, Gulton has a six acre lot full of barium titanate rejects. Devices using the material cost $5000-$10,000 per pound according to estimate of Endevco Corp., a competitor in the piezo-electric instrument field.

•

Watch it boys! Original plans to use a two-tone audio signal on a rf carrier to turn satellite's electronics on and off have changed. One tone will be used. Previously reported in this column was big concern of satellite scientists as to whether high-school kids and other amateur hams might build equipment to detect satellites passing and find the key tone to turn it on. John T. Mengel, the satellite's electronics designer says the one tone system will be used because of weight saved. If you don't think weight is a problem, here's the answer. Removal of one tone saves 3 ounces! The press knows the approximate frequency to be used. Let's hope it doesn't broadcast it.

•

It had to happen! A new company known as Kentron Hawaii Limited, Honolulu, advertises: "Why Honolulu? Honolulu is a modern American community in the center of the Pacific and is *2400 miles closer to military electronic problems* in the Pacific area than the west coast of the United States." Kentron manufactures tubes and supplies engineering design services.

New Genisco Centrifuge subjects two 300 lb. assemblies to 100 G's

Genisco's Model E185 G-Accelerator, capable of subjecting complete electronic and mechanical systems to G-loadings that simulate actual flight operation, incorporates numerous unique features that simplify operation, reduce servicing, and allow precision testing to meet the most stringent military specifications.

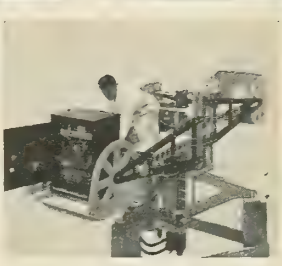
The absence of belts, pulleys, and gears permits smooth and vibration-free rotation of the 12-foot rotor so that delicate inertial guidance systems can be tested. The machine is rugged enough, however, to accommodate proof-load testing.

Operation is unusually simple. Operator responsibility has been minimized, with many operational functions being accomplished automatically. Numerous built-in safety features afford maximum protection to both personnel and the machine.

These design features, plus wide flexibility in the use of the machine, reduce maintenance requirements, and together with low initial cost make the Model E the best large centrifuge currently on the market. Complete specifications will be sent on request.

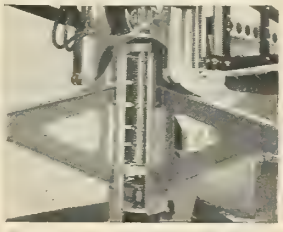
SMOOTH, CONSTANT ROTATION—Hydraulic drive system permits a clean, compact design. Problems of backlash, gear noise, and frequent lubrication are eliminated. Wow and drift during a one-minute period are less than 0.5% of the operating rate at any speed.

SIMPLE SPEED CONTROL—A single handwheel, located on a remote-control console, determines boom speed. Speed adjustments are made quickly without reading complicated scales or dials.



AUTOMATIC DYNAMIC BALANCING—The boom seeks a dynamically balanced condition automatically. Manual computation to determine centers-of-gravity is eliminated.

BOOM SPEED EASILY MEASURED—Coarse speed indication is accomplished by a specially-calibrated tachometer, accurate to within 1% of actual speed. Precision measurements are provided by a pulser/electronic counter, on a 4-decade digital display.

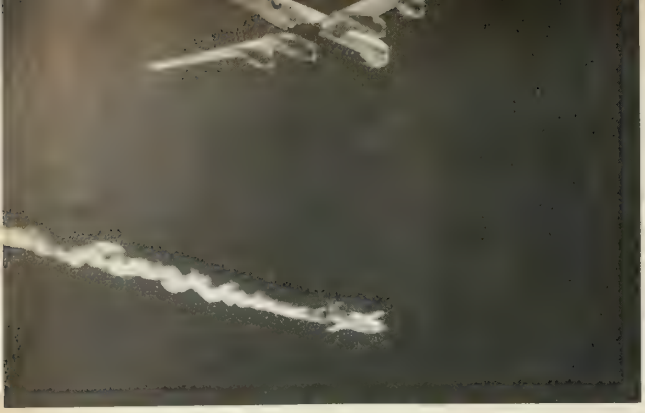


REDUCED HORSEPOWER REQUIREMENTS—By utilizing aircraft design techniques and enclosing the structure in an aerodynamically clean compartment, horsepower requirements are reduced to 15 h.p. for a 100-G machine.

BUILT-IN SAFETY FEATURES—Eight safety interlocks, including three which are key-operated, prevent the machine from being started inadvertently. Removal of any key renders the machine inoperable, permitting the operator to make adjustments to the test object in absolute safety.

CLOSED-CIRCUIT TELEVISION SYSTEM—A closed-circuit industrial television system, incorporating a camera, control unit and remote video monitor, can be provided as auxiliary equipment for the optical surveillance of test objects under acceleration.

MOUNTING PLATFORMS LOCK IN FIVE POSITIONS—The mounting platforms can be locked in the horizontal, 45°, 90°, 135°, and 180° positions, permitting test objects to be subjected to G-loadings through several axes without demounting.



SLIP RING SYSTEM—A total of 48 slip rings are provided as standard equipment in a configuration of 24 unshielded leads rated at 14 amperes maximum, and 24 shielded leads rated at 1 ampere. Brush holders have been removed in the above photograph.

REMOTELY OPERATED—A control console permits complete operation of the rotor assembly from a remote position. All operating controls and switches are located on the console panel.

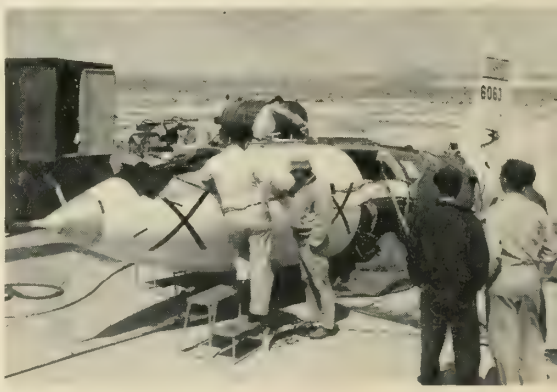
Circle No. 33 on Subscriber Service Card

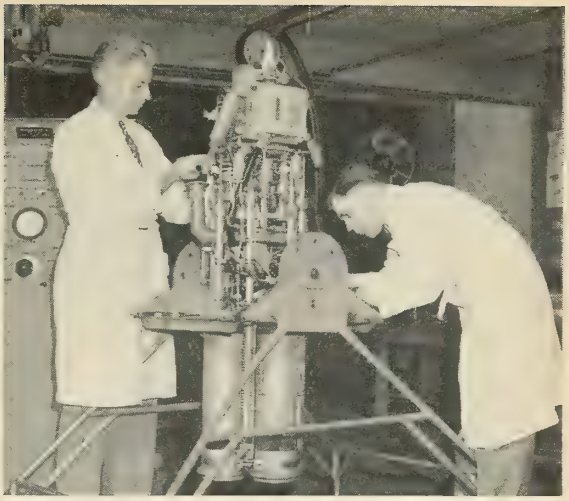


The Bell X-1E was carried aloft by a B-29 over Edwards AFB a few weeks ago for its maiden flight. These exclusive in-flight shots of the X-1E shortly after having been released from the B-29 (and chased by a tracking aircraft) were taken by Loyd Mallan, aviation and science writer. The copyrighted (1957) pictures will appear in Mallan's forthcoming book Rocket Test Pilot.

m/r exclusive:

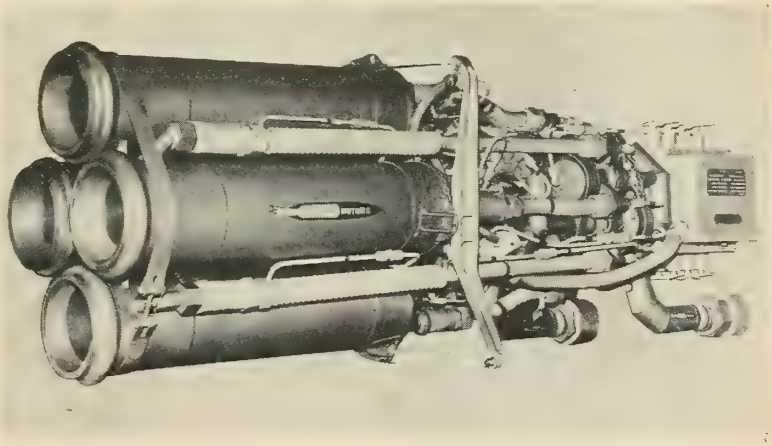
X-1E Goes Aloft

X-1E is prepared for hook-up to its B-29 mother plane. Pilot's breathing oxygen system is checked at Edwards AFB. X-1E uses advanced pilot ejection seat equipment and modified fuel feed system.

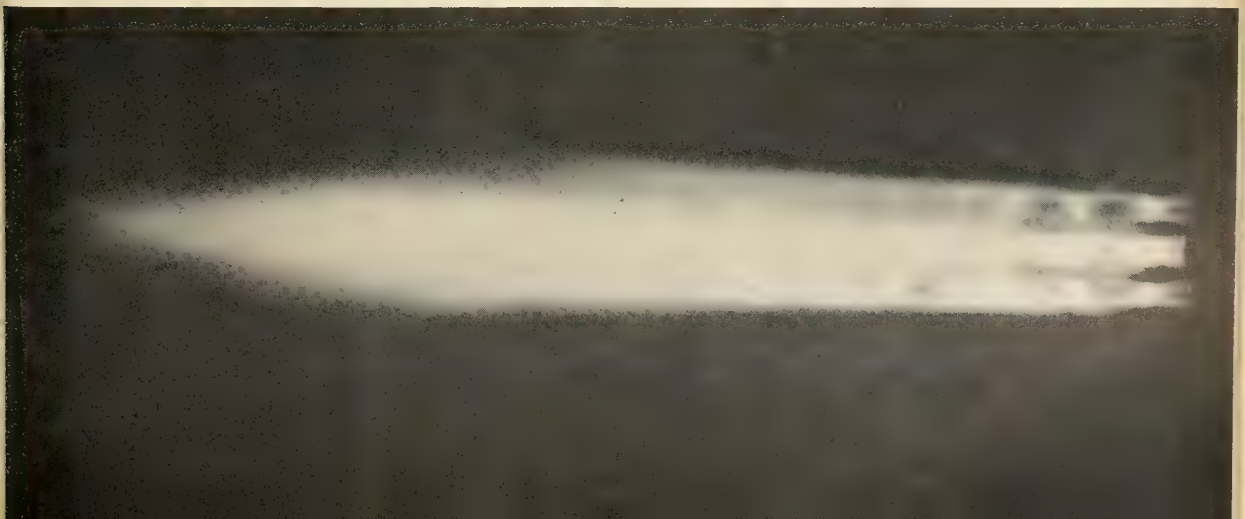


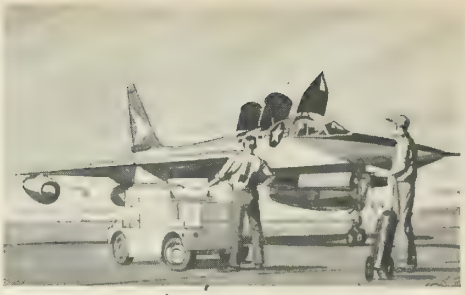
Airplane is readied by NACA, Bell and RMI engineers. First flight lasted for a few minutes and was successful. Landing gear was slightly damaged at landing, delaying the second flight.

The NACA X-1E research aircraft was modified from original X-1 (No. 2) employing 4 per cent thick wing (thickness measures per cent of wing cord) produced by Stanley Aviation Corporation Denver, Colorado. Aircraft is built by Bell Aircraft Corporation



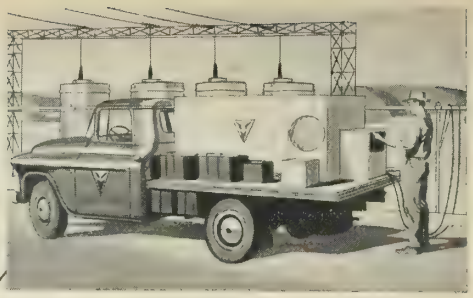
Oxygen is vented to the atmosphere as propellant tanks are being topped prior to takeoff. X-1E has fuel supply for about four minutes. The aircraft obtained a maximum velocity of Mach 2 plus during the first flight. No speed record run was attempted.





RMI employees, John Wickstead, left, and Holbrook Smith, perform operational check on the 6,000 lb. thrust engine in preparation for test firing. Engine used in the X-1E is designated XLR11-RM-11, basically the same as the one used in the original Bell X-1.

Reaction Motors, Inc., a pioneer company in liquid rocket aircraft engines, has produced a whole series of the 6,000 lb. thrust power plants of the kind employed in the X-1E. The four chambers can be fired simultaneously or in any sequence or combination of one, two, three and four. Each chamber produces 1,500 lb. thrust. Output is controlled by cutting off one or more chambers. Engine uses liquid oxygen and alcohol; pump drive employs peroxide and catalyst.



Static test of RMI's FLR11-RM-11 rocket engine at company's New Jersey facility. These engines have been built under both Navy and Air Force contracts. RMI now is working on similar power plants of much higher thrust for tomorrow's experimental rocket aircraft.

New gas turbine engine proves its versatility

JUPITER GAS TURBINES provide reliable power for a wide range of military and industrial uses. Simple and rugged, compact and lightweight, the 500 hp Jupiter offers many advantages over conventional power plants. New users praise its high power-to-weight ratio, its instant starting even under severe temperature extremes, its easy portability and low maintenance requirements. Experience has proven the effectiveness of Jupiter gas turbines for power generation, boat propulsion, mechanical drive and still other applications. Perhaps this versatile engine can help solve your special power problems. Write for new Solar gas turbine brochure... Dept. D-50, Solar Aircraft Company, San Diego 12, California.

at the start of the IGY . . .

Project *Vanguard*

Past, Present and Prospects

VANGUARD MAY make it after all if it can clear the red tape. Office of Naval Research Head Rear Admiral Rawson Bennett promises that the first *Vanguard* vehicle will be ready to try to launch a satellite "in the spring of 1958." Meanwhile the first blush of pride and prestige that flushed the egos of the major subcontractors pales into anger as Project *Vanguard* wallows in fantastic bureaucratic mire.

During the International Geophysical Year the U.S. will launch 193 research rockets to altitudes up to 200 miles from Fort Churchill Canada; White Sands N. M.; Guam; and from ship board from pole to pole. These will include 42 *Aerobees* 14 *Nike-Deacons* 52 *Nike-Cajuns* and 85 *Rockoons*. But from a publicity point of view at least the six scheduled U.S. attempts to place four artificial satellites in orbit is the biggest deal of all.

It's also big from a money point of view. Traceable costs of the $39-million project already exceed $50 million. Real total may top $100-million.

Eulogized and advertised ad nauseum as mankind's greatest adventure there is still no assurance that any of the *Vanguard* satellite-launching attempts will be successful during the 18 months of the IGY. It's the nature of the still-young state of the rocket art.

Even if *Vanguard* is ready by spring, it still may not be first. Reports point to a Russian try within 10 weeks. And to the south the missile team everybody tries to ignore may beat even that date.

For some still unexplained reason, no *formal* approach has ever been made to the highly successful Wernher von Braun rocket team at Redstone Arsenal, Huntsville, Ala—despite the fact that *Redstone-Recruit* satellite launching hardware has been in being at the arsenal for nearly a year now.

Off the record, however, Dr. John P. Hagen, Project *Vanguard* Chief, and his Naval Research Laboratory associates have more than once gazed with interest if not envy, on Dr. von Braun's stepping stones to space flight. And, within the last few months, the Army has developed its own satellite transmitter. There seems to be a possibility, in fact, that the Army may have been placed on unofficial stand-by alert—just in case.

The recent three-day special meeting of the U.S. National Committee for the IGY at the National Academy of Science, Washington, D. C., provided the most details of the official satellite program released to date. Particularly revealing were papers by Dr. Hagen and by Dr. R. W. Porter, Chairman, Technical Panel for the Earth Satellite.

Project *Vanguard's* target is to place an instrumented sphere with a diameter of 20 inches and a gross weight of 21½ pounds in an orbit at a nominal altitude of 300 miles—perigee no less than 200 statute miles and apogee no more than 1400 miles—with an inclination of the orbit to the equator of 40° ± 5°; to be launched from Patrick Air Force Base, Fla. Required orbital velocity is 25,000 feet per second. Latest estimate puts its period at 100 minutes.

The original idea, according to Dr. Hagen, was to use as many "off-the-shelf" components as possible; "to use a configuration for which the preliminary design had already been done and to employ a rocket vehicle contractor who had intimate and recent experience in the design and manufacture of research rocket vehicles and who had experienced engineering personnel."

Prime vehicle contract went to The Martin Company, which had previously made the *Vikings*. General Electric received a subcontract to modify the less-than-20,000 pounds thrust *Hermes* engine into an over 27,000 pounds thrust *Vanguard* first stage. Aerojet-General would adapt the Aerobee main engine into a second stage.

Selection of a three-stage vehicle with a minimum gross weight of 20,000 pounds required, Dr. Hagen said, "a *minimum* thrust level for the first stage (for safe takeoff) of 27,000 pounds . . . (This) dictated to a large degree the characteristics of the remaining propulsion systems."

This prediction of stages two and three by stage one may explain why GE's hopped-up *Hermes* engine, was first rejected as unsatisfactory and then hastily and unexplicably reinstated. Had it been dropped, the whole project might have had to be re-engineered. Meanwhile, it isn't certain the first stage engine's problems have yet been solved. G.E.'s Dr. Porter, referring to the fact that the last of the Nunn-Baker satellite cameras will not all be in place before March, 1958, said: "This may therefore be the limiting part of the entire satellite program, *with the possible exception of the booster vehicles.*" He could also have been talking about his own company's first stage engine.

An example of how *Vanguard's* too many generals have really hauled out the red-tape lies in the difficulty of finding out just what *is* going on. Obtaining specific information from the various *Vanguard* chiefs and contractors is now almost impossible.

The "security" system for controlling the release of information about this project of "no military significance" seems more calculated to give everyone a chance to check for possible embarrassment. The system would do justice to political censorship in the Kremlin!

No information may be released under the name of any Martin Company subcontractor unless it has first been checked either for "technical accuracy, military security or both" by: The Martin Company; NRL's Technical Information Office; NLR's Security Office; Admiral Bennett, ONR; Office of the Chief of Naval Information; Department of Defense Office of Public Information (including representatives of Army, Navy, Air Force and DOD); Central Intelligence Agency; State Department; National Science Foundation; and National Academy of Science (U.S. Committee for the IGY).

Since, in the final analysis, NRL alone would suffice to assure technical accuracy and protect military security, it must be assumed that *Vanguard* is politically a very sensitive vehicle. Says one important subcontractor: "It is just disgraceful!"

However, m/r has been able to determine that: Aerojet-General's second stage engine is ready to go—no troubles; Grand Central Rocket's third stage flew on the nose of *Viking-14* and "performed like a doll"—no troubles; Raymond Engineering Laboratory's spring-loaded satellite ejector mechanism "is perfect" according to NRL engineers; Atlantic Research has all but finished work on the spin and retro rockets for separating the second stage from the third; Minneapolis-

Honeywell's gyro reference system also appears to be trouble-free and on schedule; Brooks & Perkins' delivery of satellite spheres is ahead of schedule; Allegany Ballistics Laboratory seems to have overcome its early burning problems; Loewy-Hydropress has already delivered the static test and launching platform to Patrick; NRL has instrumentation and circuitry for the satellites well in hand.

Bendix Radio Division is on schedule in the manufacture of Minitrack receiving stations; the 80 U.S. Moonwatch teams have been organized; the Nunn-Baker satellite tracking camera is reported to be experiencing mechanical difficulties, but Perkin-Elmer's optics will be delivered in time for the last of the 12 cameras to be in place by next spring; International Business Machines' 704 satellite data computer is in place and ready to go whenever a satellite is launched; and Army Signal Corps is busy arranging for the instantaneous transmission of satellite data from South American tracking stations.

This quick look at Project *Vanguard's* status would seem to leave the burden of proof of success or failure up to the prime systems contractor, The Martin Company, and the first stage engine-maker, GE. However, a lot of components haven't yet been flown, and until they experience an actual launch and flight, their true readiness will not really be known.

In this last connection, the next *Vanguard* test vehicle shot, TV-2 (TV-0 and TV-1 were *Vikings*), will be a GE first stage with dummy second and third stages loaded with measuring and transmitting gear. If it works, O.K. If not, somebody's got to hop, and fast.

TV-3 will be a GE first plus Aerojet second plus dummy third stage. TV-4 is slated to be the same as TV-3 but with an ABL third stage. TV-5 and TV-6 should be full system test firings —a total of seven test flights before the first shot in earnest.

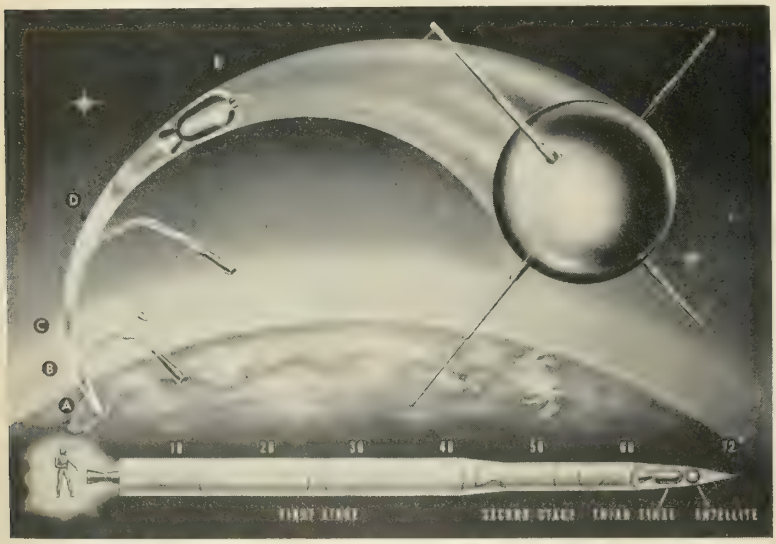
Statistically, the *Vanguard* launching vehicle is 72 feet long; has a first stage diameter of 45 inches and a second stage diameter of 32 inches. It is finless, employs integral tanks and has a loaded gross takeoff weight of 22,600 pounds.

Its first stage is a liquid oxygen and kerosene motor fed by turbine-driven pumps. Orientation and flight path are maintained through control of the gimballed motor. "The electro-hydraulic controls that position the motor have the necessary response to stabilize the composite finless airframe in pitch and yaw."

Roll control comes from changing the direction of the turbine exhaust. The inertial reference system for guidance is carried in the second stage. In Dr. Hagen's words, "In essence, the first stage is a guided, liquid propellant booster which provides about 65 per cent of the energy to raise the remaining stage to orbital altitude and about 15 per cent of the required orbital (horizontal) velocity."

The second stage uses white fuming nitric acid and unsymmetrical dimethyl-hydrazine fed directly from high pressure integral tanks. In both first and second stages the pressurizing gas is helium. Motor is gimballed, as in the first stage. "An array of gas jets provides roll control during second stage powered flight and complete control of vehicle orientation during coasting flight."

The reference system and flight programmer, both located in the second stage, are responsible for all major in-flight operations, such as change of pitch rate with altitude. The third stage spinning mechanism is also in the second stage.



This stage which, fully loaded and including the third stage, weighs about 4800 pounds, contains the brain of the launching vehicle, and supplies the remaining energy required to reach orbital altitude and about 32 per cent of the orbital velocity.

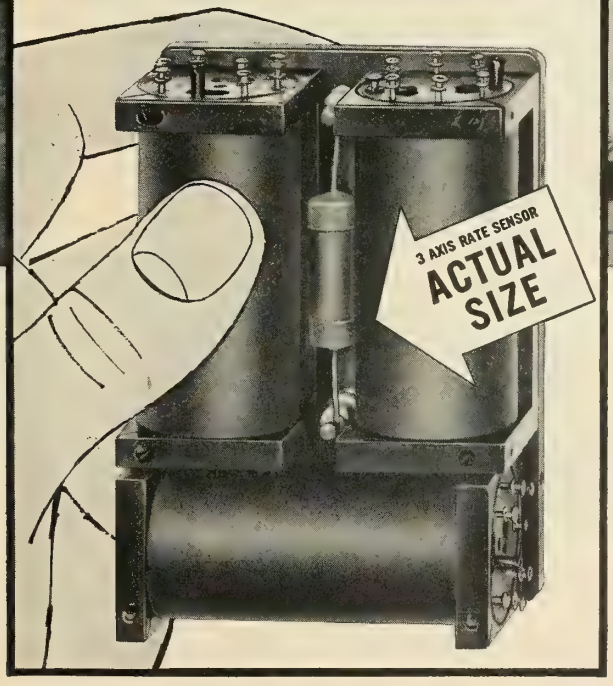
The third stage weighs about 500 pounds fully loaded and is an unguided solid propellant rocket, spin stabilized with its longitudinal axis roughly parallel to the earth's surface. It is fired at orbital altitude and provides 50 per cent of the required orbital velocity, the remaining three per cent coming from the earth's rotation. rotation.

The sequence of events in a "typical" firing will be as follows: vertical flight until "satisfactory" clearance of ground installations; then maintain an approximate zero-normal-force trajectory until aerodynamic forces are no longer critical; first stage separation and second stage start up; jettison nose cone, revealing third stage and satellite, in latter part of second stage powered flight; pitchover after second stage cut-off so that third stage will be fired roughly parallel to the local horizontal; second stage separation and third stage firing; third stage fires until orbital velocity is attained; saltellite ejected from third stage with a differential velocity of three feet per second.

The six planned business shots will hope to get four satellites successfully into orbit. These four will perform basic experiments as follows: NRL's ultra-violet, temperature and meteoric measurements; University of Iowa cosmic ray and AF meteoric experiment; NRL magnetometer and NACA expandable plastic foil sphere experiment; and for the fourth one, a choice to be made "shortly after November first" between University of Wisconsin energy balance and Signal Corps cloud distribution experiments.

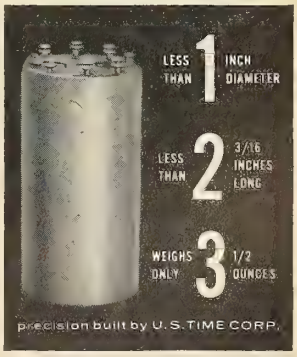
Design of equipment for all five of these projects appears to be progressing on schedule and without major hitches.

A bird is an industry: At (A) Loewy-Hydropress supplies launching platform; GE, the first stage engine; at (B) first stage falls off; second stage engine is by Aerojet-General and contains gyro reference system by Minneapolis-Honeywell, spin and retro rockets for separating and spinning third stage by Atlantic Research; at (C) during second stage powered flight, nose cone pops off; at (D) second stage falls free and third stage either by Allegany Ballistics Laboratory or Grand Central Rocket propells satellite to orbital velocity; (E) Raymond Engineering Laboratory's ejection device kicks sphere loose with three foot-per-second differential velocity over dead third stage assembly, which becomes a kind of satellite itself.



In Control–with U. S. TIME GYROS

Poised on their launchers, the Navy's Terrier guided missiles... Official U. S. Navy photograph.



MICROSIZED!

Roll, pitch and yaw rate control gyros in one compact package weighing less than one pound!

United States Time Corporation offers the systems manufacturer the long sought after optimum performance/weight ratio in Gyroscopic Instruments. The 3-Axis Rate Sensor package achieves high performance in one third the weight and volume of previous rate gyros. Flight proven under severe environmental conditions, microsize gyros and gyro packages can be supplied in production quantities to satisfy your specific requirements.

More than seven thousand of these precision-built rate gyros are currently in use.

U.S. Time's Research Staff and facilities are engaged in research, design and development directed toward new products and optimization of the performance/weight ratio in the following fields of precision instrumentation.

• STABLE PLATFORMS • FLOATED INTEGRATING GYROS
• ACCELEROMETERS • RATE GYROS • 2 AXIS GYROS • DAMPER SYSTEMS
• INERTIAL INSTRUMENTATION • GUIDANCE SUB-SYSTEMS

A new edition of our technical data handbook available upon request.

WORLD'S LARGEST MANUFACTURER OF WATCHES

Creating New Frontiers for Scientific Exploration...

Extremely accurate photo-theodolites being used in guidance research at JPL

JPL, pioneer in jet propulsion from its earliest stages, has drawn together engineers and scientists whose talents embrace practically all of the physical sciences.

Working in their chosen fields, supported by excellent facilities and given unusual opportunity for individual initiative, these men are now actively engaged in solving the complex scientific problems leading to the advancing new era of technological development.

The Jet Propulsion Laboratory, under U.S. Army contracts, has broad interests and maintains a constant search for new approaches to the myriad technical problems posed by the rapid advance of modern science. As a result, exceptional opportunities for those creative individuals interested in such activities are provided at the Jet Propulsion Laboratory.

ELECTRONICS EVOLUTION

The 1957-60 missile era may some day be referred to as the period in which electronics first came into its own as a 50 per cent partner dollar-wise with the missile frame and propulsion business.

The specific spending picture for missile electronics is clouded by security and hidden factors in any accounting breakdown available. Despite this, a conservative estimate for 1957 spending shows electronics to be well along toward 25 per cent of the total $2.3 billion missile business.

Of the approximately $600 million for electronics about half is for missile-carried gear and the other half for ground gear. For the Air Force alone the dollar volume picture for aviation and missile electronics will expand over 100 per cent in the next few years, according to a recent estimate of USAF Maj. Gen. David Baker, Air Materiel Command. The Navy and Army needs must be added to this.

As things stand by 1960 a predicted $1-billion missile electronics business seems as sure as the importance of making missiles go where we want them once they are fired.

At the present time missile guidance and control in operational, developmental and research missiles ranges from the "puppet-like" guidance of the Army's *Dart* through a wire cable attached to the missile to the ultra-sophisticated (for 1957) attempts to design a 5000-mile ICBM that will reach its target point without any ground-communication guidance over at least half its trajectory.

Between these two extremes are various systems using either electromechanical inertial techniques coupled with some electronics or pure electronics for guidance.

These might be defined as:

Closed-loop guidance:

1) *Nike* is typical of this method, as are the new *Talos* and *Terrier*. *Nike's* guidance is based upon information acquired by radar, calculated by a ground based computer and then sent to the missile as commands. Even the firing of *Nike's* three warheads is done by command.

Talos and *Terrier* use a refinement of this technique. They seek out the rider beam of a two-beam radar and then switch over to a proximity system during the terminal part of their flight. The beam system uses track and capture beams sent by one radar antenna system. The track beam follows the target. After launching, the missile seeks the capture beam that leads it to the target's vicinity.

2) *Bomarc* utilizes computer-derived information from the Semi-Automatic Ground Environment system being implemented for continental defense. *Bomarc's* position is relayed by data link equipment on board to a SAGE center. Directions for interception of its assigned target come back to it through the data link for guidance to the terminal area. Near its target it uses radar equipment similar to interceptor fire control to "lock-on" to its target for a kill.

Self-contained:

Early user of this technique was *Matador*. An inertial system on board is distance-direction programmed to carry the missile to its target and to program the terminal dive. Recently reported was guidance of *Matador* by utilization of low frequency hyperbolic navigation signals such as produced by Decca, Cytac and Radio-Web.

Snark and *Navaho* use a hybrid system combining inertial navigation with celestial position fixing. The enroute flight is preprogrammed through the inertial system and periodically corrected by automatic star-sighting equipment on board.

Target seeking:

Early user of this technique was the *Corporal*. The same technique seems to be the mainstay of current hopes for ballistic missile "guidance." The short range *Corporal* is guided during the first part of its flight by radio commands. These are derived from Doppler radar and optical data on the missile's initial trajectory. Adjustments to correct the trajectory are sent to establish the required ballistic path for a particular target. The same general technique is applied to *Redstone* and is believed planned for missiles such as *Atlas, Titan* and *Jupiter*.

Guidance of an ICBM has been described as "shooting through a hole in the sky 800 miles up." That "hole" will be the ideal point in outer space for the ICBM to go through if its calculated ballistic trajectory is to carry it to the target. But how is "hole in the sky" found and how can the missile men be sure of the trajectory?

There have been numerous reports that radiometric corrections will be applied to the ICBM flight during the find-the-hole flight stage. Other reports have said that radiometric correction was abandoned in favor of inertial programming.

The handicap of intense ionization around an ICBM and the inability of radio energy to penetrate the ion sheath would probably limit the range over which control could be exercised. Once up to full speed, radio control could be impossible. Inertial control would not have this handicap, but would probably be less accurate than the best radiometric techniques.

Although the manufacturers of gyroscopes and accelerometers have made phenomenal progress in raising the precision of guidance it seems apparent that in the long run electronics will win out. It's hard to compete with the speed of light and precision control advantage in radiometric methods.

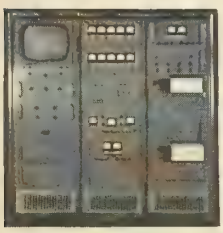
A big item in planning for ICBM operational centers are the computers that will be needed. They will undoubtedly do the job of taking the myriad and varying conditions under which an ICBM will perform and integrating them to determine where that "hole in the sky" should be at any given time and place the ICBM is launched.

Only recently Cornell Aeronautical Laboratory dedicated an IBM 704 scientific computer for ICBM work. Purpose, it was stated, is to provide a complete table of properties of air at high temperatures. Over half-million thermodynamic values covering the properties of air for some 8000 different cases of temperature and density will be computed.

Microminiaturization of electronics is just starting. With improved sensors and high power computers in a tiny package missiles may some day need only the latitude and longitude of the ground target to find their way at any speed and from any altitude.

This same electronic "brain" together with ultra-advanced sensors may also make possible counter weapons capable of seeking out and destroying missiles attacking from outer space.

TELEMETERING BY ASCOP



The LACROSSE

translating data accuracy to DEADLY ACCURACY!

The Army's brilliant Lacrosse surface-to-surface guided missile — now in production at The Martin Company — can pinpoint and destroy enemy strong points in the field, supplementing air and artillery in support of ground forces. A highly mobile, all-weather weapon, it can be fired from a truck-mounted launcher with great rapidity.

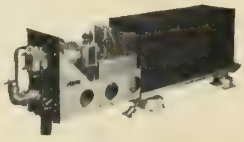
The Lacrosse graduated from the design stage into a production weapons system at a considerable savings in cost and time, due to cooperation between the Cornell Aeronautical Laboratory which designed it, The Martin Company which produced it, and ASCOP High Level D Series Telemetering, which recorded every phase of development and test, from the first triggering to the last shudder.

As many as 580 channels of data may be sampled, transmitted and/or recorded with an accuracy of better than 1% by ASCOP Telemetering Systems. ASCOP has the "packaged" answer to data-recording for your project, too . . . whether it involves aircraft, missiles or other vehicles . . . operational or static testing. Our engineering staff stands ready to consult with you, without obligation.

M SERIES GROUND STATION

ASCOP DATA REDUCTION EQUIPMENT

ASCOP Pulse Width Ground Station equipment complements ASCOP PW Multicoders and radio telemetering sets to provide complete "packaged" systems for operational testing of aircraft, missiles and other vehicles and for static testing of engines, rockets, nuclear reactors, etc.



MC-1 MONITOR CONSOLE GROUP

ASCOP DATA ACQUISITION EQUIPMENT

"D" SERIES PW DATA EQUIPMENT

For aircraft, mobile or other applications where recovery or continued use is practical and where space and weight are not critical. Samples up to 43 data sources.

LOW LEVEL PW MULTICODERS

Provides super-sensitive low-level remote measurement of data from airborne vehicles. High input sensitivity, fast sampling rate, wide selection of data channels.

U.S. Army's NIKE AJAX

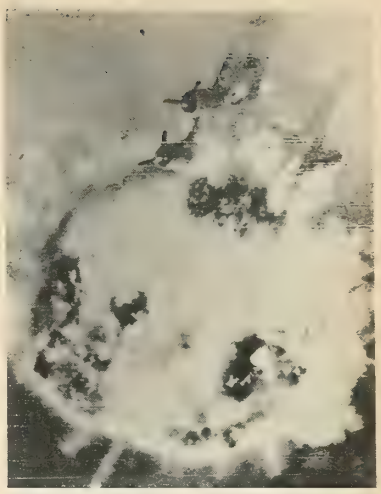
Nike-Ajax, named *Nike* after the Greek goddess of victory, is the Army's first supersonic antiaircraft guided missile designed to intercept and destroy the enemy target regardless of evasive action. *Nike* guided missile units are now deployed around vital industrial, highly populated and strategic areas of the U.S.

Nike-Ajax is a missile about 20 feet long and about one foot in diameter, with two sets of fins for guidance and steering. It is boosted to supersonic velocity by a solid-propellant booster and maintained by a liquid sustainer motor. The missile and booster weigh more than one ton.

Speed, range, altitude and lethality of *Nike-Ajax* can meet an attack from any direction and its kill potential has far exceeded expectations. There are 12 launchers in each *Nike* battery, each battery being operated by approximately 100 officers and men. Personnel are trained at the Anti-aircraft and Guided Missile School, Fort Bliss, Tex., and the Ordnance Guided Missile School, Huntsville, Ala.

The *Nike-Ajax* system consists essentially of a two-stage missile and elaborate control equipment requiring approximately 1,500,000 separate parts. The missile is about 20 feet long and one foot in diameter with two sets of fins for guidance and steering. Its weight is more than one-half ton.

Inside the *Nike* are an explosive warhead, a guidance unit, and a propulsion system consisting of two propellant tanks, an air tank, and a rocket motor. When the missile takes off, the initial seconds of flight straight up are powered by the solid propellant booster rocket which drops off before the *Nike* turns and heads for the target at supersonic velocity. After the booster falls away the missile's own rocket motor begins to generate power and the second stage of the trajectory begins.



Control equipment consists mainly of three radars, an electronic computer, and automatic plotting boards. This is the combination of intelligence that detects approaching enemy aircraft and directs the *Nike* to the spot in space where they will meet and the warhead will be detonated.

Nike Ajax batteries ring most important cities in the U.S. today. Missile has demonstrated its kill capability against slow drones. Nike still is considered effective.

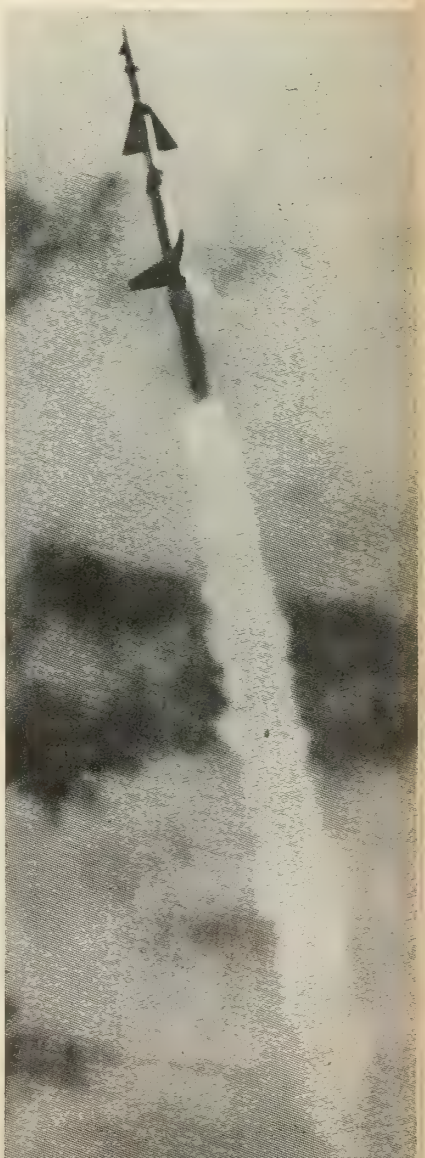
First of the radars, the acquisition radar, detects a target aircraft at long range and alerts the battery control area. A second radar, called the target tracking radar, picks up the aircraft at a closer range. Then information of the target's position and speed is continually fed to an electronic computer whose job is to keep track of the target and the missile when launched, so that it can determine the commands to be sent for optimum interception.

In the meantime, the third radar which follows the missile, supplies information on the *Nike's* position to the computer. Commands to direct the flight are determined by the computer and transmitted to the missile's guidance components which in turn cause the steering fins to move in the proper direction. Any evasive action by the target is instantly detected by the target-tracking radar and transmitted to the computer. The computer re-evaluates the trajectory of the missile to meet the target's change of direction and appropriate steering signals are transmitted to the *Nike*.

The *Nike* battery control officer sits in his control van located in the same area as the three radars and computer. He is responsible for the execution of the entire operation and he alone makes the final decision to fire. Information is constantly fed into the control console to enable him to make this crucial decision.

When notified by early warning radar networks of unidentified aircraft approaching his defended area he orders "Battle Stations!" and sets the launching into action. Previously prepared missiles and boosters are raised to the ground surface on elevators from the underground launcher installation. Propulsion and guidance components have been previously checked, propellant tanks filled with acid and JP-4, and the warhead installed. *Nikes* are loaded on the four launchers associated with each underground installation and final tests and checks are then completed.

When unidentified aircraft come into the range of the acquisition radar the information is presented on the scopes in the battery control van. The target is still far away and out of sight of everything but the radar's searching beam, but at this point the control officer gives the word to "Engage!" and the command is relayed to the launchers. The missiles now are erected to firing position.



Next the battery control officer must decide when to fire. Hesitation or a mistake might let the bomber slip in close enough to drop his atomic weapon. The battery is placed under its final "red" alert status and the missile tracking radar slews and locks on the first missile to be fired. As the target approaches the maximum range of the *Nike*, the firing button is pushed.

Nike Ajax being boosted to altitude in test firing. Douglas Aircraft developed the Ajax. Western Electric produces guidance equipment. The system consists of 1.5 million parts.

U.S. Army's HAWK

Despite the frightening array of super-weapons funneling down the research and development pike, warfare sooner or later gets down to the messy foot-sloshing business of ground-fighting. This means low-flying attack aircraft and short-range missiles doing a tactical airpower job must be contended with.

The Army's answer to this requirement is a highly mobile missile called the *Hawk*.

Approximately 17 feet long and 14 inches in diameter, the *Hawk* is deployed on an unusual triple launcher from which three of the weapons can be fired in rapid sequence against low-flying aircraft.

Development of the new air defense system was carried out by Redstone Arsenal scientists under the direction of Dr. Martin Schilling.

Hawk is described by the Army as capable of operating both in the continental U.S. air defense complex at fixed installations as well as with mobile combat troops of the field Army. It may be transported on the highway with a minimum of vehicles or flown by helicopter or aircraft. It will be adopted both by the Army and the Marine Corps.

The new *Hawk* will probably be installed first at sites in the New York City and Washington-Baltimore areas and later at emplacements in other cities where it will very likely replace or supplement the *Nike* chain of air defense weapons. Each battery will require some 40 acres for emplacement.

Prime contractor for the *Hawk* is Raytheon Manufacturing Co.'s Andover, Mass., plant. Northrop Aviation Co. of California is the major subcontractor. *Hawk* uses a solid fuel engine developed by Thiokol Chemical Corp. at its Redstone Arsenal installation.

Hawk uses guidance techniques said to be unusually successful in hunting down and destroying attacking aircraft. Unusual radar instrumentation has been designed and installed in the *Hawk* to gain effectiveness in the so-called "blind zone" of conventional radars. It has also been spoken of as a possible bomber defense missile.

Pilot production of the *Hawk* has already begun at Raytheon, with full production scheduled for the near future.

U.S. Army's NIKE-HERCULES

Integration of *Nike-Hercules,* Army's latest surface-to-air defense missile, into existing *Nike-Ajax* batteries will begin within the year. An advanced version of the *Nike-Ajax,* the *Hercules* has about three times the range of the operational *Ajax*. The final testing phase of the *Hercules* is being conducted at White Sands Proving Ground, N.M.

Hercules is actually a "double" *Ajax*. It is longer, heavier and more than double the diameter of *Nike-Ajax* and capable of extreme maneuverability at altitudes far in excess of those achievable by the *Ajax*. The most outstanding feature of the missile is its three-barreled solid-propellant booster. The increased rate of climb to altitude will permit swifter interception of the most advanced types of aircraft and its vastly increased range will make it the most effective operational air defense missile in the United States.

The atomic warhead of the *Hercules* is designed to insure that detonation occurs only at altitudues sufficiently high to prevent damage to friendly surrounding terrain. It can engage and destroy single or formations of aircraft.

The missile is 27 ft. long, 2 ft. in diameter; booster is 14.5 ft. in length. It is reported to have a slant range of approximately 70 miles.

The design, development and production of the missile system by the Army is the result of extensive coordinated efforts by the Army Ordnance Corps, Western Electric Co., Bell Telephone Labs., and the Douglas Aircraft Co. The *Nike-Hercules* is to be produced initially at the Douglas Aircraft Santa Monica plant and followed with additional production at the Douglas-operated Charlotte Ordnance Missile Plant at Charlotte, N.C.

Fuels and acids used in the missile for propulsion have contributed to corrosion in present *Nike* models. The incorporation of a solid propellant sustainer unit in *Nike-Hercules* will eliminate the corrosion problem. Fueling, handling and storage problems for *Hercules* launching sites will be simplified or eliminated completely.

Meanwhile, the Army has requested funds to support continued development of the *Talos* as a possible supplement to *Nike-Hercules.*

U.S. Army's

DART

The Army's end-product concern remains ground-fighting. This means foot-soldiering and everything that goes with it, not the least of which are heavily armored, heavy fire-power vehicles such as the modern tank.

By the end of World War II a reasonably effective series of weapons had been developed to combat these units—the bazooka and both 75 mm and 105 mm recoilless rifles. These were the first rocket power systems to be effectively used against tanks. But they left considerable to be desired.

They had to be aimed, often at a target moving 30 miles an hour. There was no in-flight guidance, and once the recoilless rifle had fired, its position was given away by its back blast. Furthermore, these weapons were within range of an enemy tank's guns.

The Army's highly mobile, versatile *Dart* suffers none of these disadvantages. The wire guided missile can be fired from either fixed or mobile positions, such as jeeps and helicopters. The *Dart's* range exceeds that of any known tank armament. Its velocity in flight is such that possibilities of shooting it down en route are very slim.

But its main beauty is the simplicity of its guidance from the point of view of the firing crew (one man, if necessary). The operator controls the flight of the *Dart* through a special telescope where his only duty is to keep the image of the missile on the image of the target. The guidance system automatically computes the problem and transmits the proper signals to the missile by means of electrical impulses through the trailing wire.

Furthermore, being wire guided, the missile is virtually jam-proof. Contrary to expectations, no problems have been reported from breaking wires. The *Dart* uses a single solid propellant rocket for propulsion.

Wire guidance for airborne missiles probably began first with the Germans near the end of World War II. They made a few firings with an air-to-ground guided missile electrically guided through a trailing wire, but they didn't have much luck. The design was never really put into service.

The French made the first real efforts to develop wire guidance, first with the Nord SS-10 and later with the SS-11. These missiles are in production in France now. Their disadvantages are that their range is less than that of a tank's guns; guidance is by straight visual reference; and the in-flight velocity is 328 ft/sec for the SS-10 and 665/680 ft/sec for the SS-11. Ranges are 1.25 and 1.85 miles respectively. Both the velocities and the ranges of these French missiles are considerably under that of the *Dart*. The French missile's main advantage is even greater portability and greater simplicity than its American product.

In one public firing demonstration the *Dart* achieved a 0.01% accuracy by hitting a cloth bullseye just six inches from dead center at a range of 2100 yards.

This missile is not yet officially operational, but is expected to be "very soon." Aerophysics Development Co. developed the *Dart*. A production contract has been placed with Utica-Bend Corp. (subsidiary of Studebaker-Packard). The rocket engine is by Grand Central; optical guidance system by Wagner Corp.

U.S. Army's

LACROSSE

Lacrosse is an all weather missile capable of destroying enemy strong points in the field to supplement air or artillery attack. Essential components of the *Lacrosse* system are the missile, a launcher mounted on a standard Army truck and a command guidance system.

Lacrosse is propelled in flight by a solid fuel rocket motor manufactured by Thiokol. Field units will be able to answer calls for fire in the same time required for conventional artillery and with a rapidity comparable to that of a 105 mm howitzer. The extremely mobile and accurate *Lacrosse* has undergone a series of successful test firings at White Sands Proving Grounds.

Lacrosse was designed and developed by the Cornell Aeronautical Laboratory of Buffalo, N. Y. Production is by the Martin Co. at its temporary Orlando, Fla. location. The recent production contract supplements an existing research contract of over $8 million.

The Martin Co. has let contracts totaling $6,031,950 with Thompson & Street Co. of Charlotte, S. C. for construction of a new plant at Orlando, Fla., location of its present *Lacrosse* missile production.

The new facility, situated on a 6,777-acre site purchased by Martin last September, is slated for use in R&D and production of newer weapons in the missile, electronics, nucleonics and small weapons fields.

Martin is handling *Lacrosse* manufacturing in interim facilities near Orlando and presumably will shift this activity to the new plant when completed later this year. Plans for the new structure calls for about 488,000 sq. ft. in four buildings. Main building measuring 640 by 500 ft. will provide 290,000 sq. ft. of manufacturing, assembly, shop and storage space.

Four fins positioned 45 degrees from the plane of the wings and at the aft end of the fuselage are movable for flight control and stability. Range of the *Lacrosse* is approximately 20 miles.

With the addition of the *Lacrosse*, supplementing the role of *Little John* and *Honest John*, the field artillery has stacked up a formidable arsenal for close support of the ground troops.

U.S. Army's

LITTLE JOHN

LITTLE JOHN atomic missile reaches for the sky after firing from White Sands, N. Mex.

For Redstone's 400-man Rocket Development Laboratories, *Little John* has been a manifold triumph. The 12½ inch, 318-millimeter rocket, about 12 feet long and packing the explosive power of heavy artillery, was successfully produced and demonstrated in a crash program that started in February 1956. It was test fired in June 1956, only a matter of months after initiation.

Honest John filled the need for a free-flight rocket artillery weapon with high accuracy, simplicity of design and operation, extremely high mobility, no electronic controls and a range equivalent to medium-to-long-range artillery.

The dimensions of *Little John* are about one-third and its weight one-sixth that of its predecessor. It can be carried in a helicopter. *Little John* thus represents perhaps the growth of a new family of rocket weapons that ease logistical problems and give Army field commanders a wider choice of warheads for use against combat targets.

It was determined that if the Rocket development Laboratories, a part of Redstone's Ordnance Missile Laboratories, directed by Col. Miles B. Chatfield, conducted the *Little John* program as though they themselves were the prime contractor, they would thus acquire invaluable experience in the painstaking coordination essential to development and manufacture of today's complex weapons systems.

Under the direction of OCO (Office, Chief of Ordnance), the task force itself provided the necessary research and development work and guidance in design control, aerodynamics, metal parts and powerplant. The Allegheny Ballistics Laboratory at Cumberland, Md., supplied propellants. Powerplant metal parts were fabricated by consolidated Western Steel of Los Angeles.

Emerson Electric of St. Louis manufactured the air frame. Army Ordnance's Rock Island Arsenal, Ill. provided the launchers. Proof testing was assigned to White Sands Proving Ground N.M. and by Redstone's own staff. Warheads came from the Army's Picatinny Arsenal at Dover, N.J.

LITTLE JOHN is 12 feet long and 12½ inches in diameter. Fins are moveable and equipped for flares.

First firing tests that saw the *Little John* prototypes burying themselves in the sands of White Sands Proving Ground thus represented careful coordination of effort. Since the production of *Little John* is conducted at Redstone, the Army is able to exercise detailed supervision over all phases of manufacture.

Little John is being developed to supplement *Honest John*. This lightweight free rocket can reach out beyond ranges of any existing tube artillery to increase further the all-weather support capabilities of the ground commander.

A great advantage of this rocket is obviously its high degree of mobility. This is the ideal "fire brigade" atomic missile for the airborne infantryman and it was developed to meet this requirement. *Little John* was first fired publicly at the U.S. Ordnance Annual Meeting in Aberdeen last Fall. Its development is well on schedule.

The first class of key personnel of the Army to be given instruction in the handling of the *Little John* began its studies on June 17th. Classroom work includes orientation in rocket parts, systems and warheads of the 12-foot missile. Ten classes are to be trained, with 20 students to a class. They will then become instructors at other Army installations.

Maj. Gen. H. N. Toftoy, Redstone commander, says the new rocket "proves to be very important in the Army's new mobile 'fire brigade' concept in the air age."

LENGTH:	12 ft.
DIAMETER:	318 mm.
SPAN:	33 in.
STATUS:	production

REMARKS: smaller version of HONEST JOHN; for GTG applications; developed at Redstone Arsenal; shorter range than HONEST JOHN; no figures released

U.S. Army's

HONEST JOHN

HONEST JOHN positioned on rails of its self-propelled launcher in preparation for firing.

This missile system is composed of the missile, a self-propelled launcher and an anemometer to measure the speed of the surface winds. The rocket is approximately 27 feet in length and 30 inches in diameter. It consists essentially of a warhead and the solid-propellant rocket motor with large tail surfaces for flight stability. The launcher is a movable, 25-foot rail mounted on the chasis of a regulation Army truck. The wind-determining equipment is pole-mounted to register the velocity of the surface winds that effect the initial flight of the missile.

Honest John's trajectory to the target is determined by the elevation and azimuth of the launcher prior to firing. The effect of the direction and speed of the surface wind at firing is considered in a final setting of the launcher. A slow spin is imparted to it by small spin rockets which give a more stabilizing effect to the trajectory.

After a few seconds of powered flight, the *Honest John* assumes a free-flight or ballistic trajectory to the target. Finally the warhead system detonates the warhead at the target. Here, in reality, is the baby brother to the 1500 mile ballistic missile, *Jupiter,* that the Army is now developing.

The *Honest John* with a 30-mile range and a maximum accuracy scatter factor at that distance of 150 yards, along with its 21-ton launching system is now air transportable in conventional military transports. Soon to be delivered is ultra-light weight launching equipment capable of being dropped by parachute.

The eight *Honest John* missile launchers currently assigned to the new streamlined pentagonal divisions give unprecedented fire power to paratroopers. A major factor in the Army's overwhelming acceptance of *Honest John* is its extreme mobility and simplicity. It can be moved about at will and fired by fewer than half a dozen men if necessary.

The first separate tactical Army unit to be armed with the 21-ton *Honest John* weapon system (developed at Redstone Arsenal, Huntsville, Ala.), is the recently reactivated 101st Airborne Division, Fort Campbell, Ky.

Named after the famous World War II outfit that distinguished itself in Holland and the Battle of the Bulge, the 101st is termed "the forerunner of divisions of the future".

Trimmed down to 11,500 men and discarding tanks and heavy equipment, the paratroopers of the 101st will serve as trouble shooters and can be completely airlifted on a few hours notice to any part of the world in only half the number of planes required for the 17,500 officers and men of present divisions.

The revamped division is composed of five combat groups of five rifle companies, each with supporting rocket artillery instead of the conventional organization of three regiments with three battalions.

Powered by a solid propellant rocket HONEST JOHN leaves rails of launcher. A slow spin is imparted to the missile by small spin rockets.

U.S. Army's CORPORAL

The *Corporal* is this country's first ballistic guided missile. The *Corporal* system consists of the rocket itself, several mobile vans and trucks of guidance and firing control equipment. The missile is about 45 feet long with steering fins located on the very ends of the large stabilizing fins. It weighs about 5 tons fully fueled and ready for launching.

The trajectory problem for the *Corporal* is somewhat simpler than that for the *Nike*. Here, the missile system is concerned with a fixed ground target so that the resulting computing equipment is not as complex. Before the missile is fired, basic firing data is computed for the guidance equipment and entered as "dial settings" in the various vans. Then, after the rocket is launched, minor corrections are made to the trajectory to insure an accurate impact.

Launching procedure is as follows: The missile is erected on its launcher by a large transport vehicle called the erector. Prior to this the propulsion and guidance components have been thoroughly checked for proper functioning, the propulsion tanks have been filled with acid and aniline, and the warhead attached.

Guidance equipment vans are placed slightly to the rear and are warmed up and checked for the required electronic indications that will guide the *Corporal* to its target.

The battery commander has established his communications for control of the firing in this guidance area. Here, also, the fire direction center has computed and determined the firing data for the target many miles behind the "enemy" lines. After the missile has been erected and final preparations completed, the commander orders all stations to stand by for the countdown to firing time.

The firing crew takes cover in the firing pit. In order to coordinate the sequence of operations before the missile is fired, the time remaining to fire (countdown) is announced over a common telephone line or "hot loop" connected to each critical station. All operators follow sets of procedures that insure complete coordination between the ground equipment and the missile as its internal components begin to warm up and prepare for the flight to the target. The commander follows the action of the operational sequence on the hot loop, and then gives the order to fire.

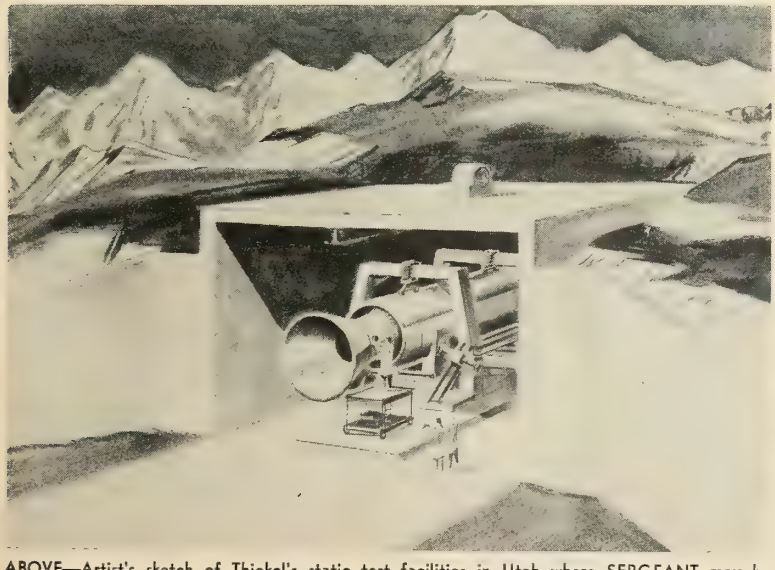
U.S. Army's SERGEANT

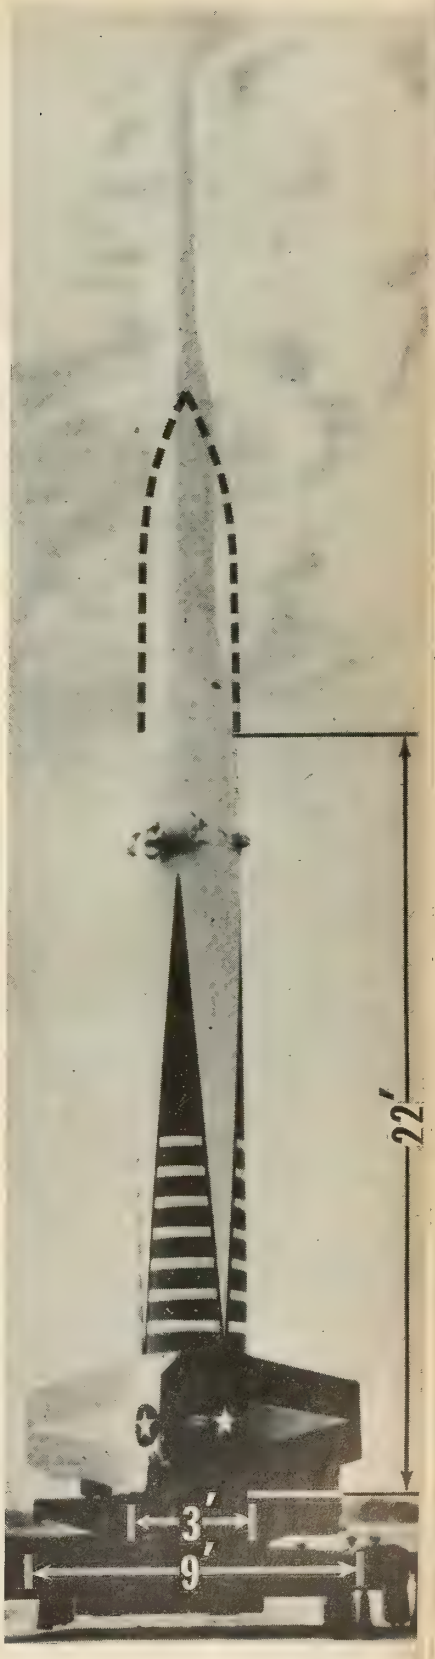
Sergeant is the latest addition to the Army's tactical missile arsenal. Powered by one of the largest solid propellant rocket motors yet developed *Sergeant* has been mentioned as a possible *Corporal* replacement. *Sergeant*, extremely mobile, safe for handling and storage and a fire mission dream is a tremendous advance over the complex and logistical problem-loaded *Corporal*.

Sergeant was developed by the Caltech Jet Propulsion Laboratory, pioneers in the field of rocket and missile research and development. Sperry Gyroscope, prime contractor for *Sergeant* production, broke ground on July 1st for their new plant at Salt Lake City. The rocket motor will be produced by Thiokol at their Utah Division facilities near Brigham City. Douglas Aircraft Co. has been unofficially reported as contractor for *Sergeant*'s airframe

Sergeant's rocket motor was developed at Thiokol's Redstone Division near Huntsville, Alabama. Testing of the production motors will be handled by the Utah Division on their new horizontal test stand. The static test facilities are capable of handling solid propellant motors up to 12 ft. in diameter and designed to withstand a two million lb. load.



The *Sergeant* has been building up an impressive record of flights as a research rocket. Modified to serve as the first-stage of the X-17 three-stage test vehicle, it has made numerous successful flights from Patrick Air Force Base, Fla. The X-17, designed to test materials for nose cones of ballistic missiles and to solve problems encountered in re-entry of ballistic missiles, is fired vertically into the atmosphere by the *Sergeant* first stage. As it starts to descend the other two stages are fired to accelerate the payload to high velocities.



The huge concrete bunker built into the rocky terrain is larger than any other test facilities of Thiokol's divisions at Elkton, Redstone or Longhorn. It is possibly the largest solid propellant test stand in the country.

U.S. Army's REDSTONE

Army's REDSTONE missile in its servicing station at Patrick Air Force Base, Cape Canaveral, Fla., is being readied for test launching out over the Atlantic Ocean.

Redstone, surface-to-surface ballistic missile, is in quantity production at the Chrysler missile plant at Warren, Mich. The *Redstone* has been described as the prototype for the Jupiter IRBM. The well-tested and successful *Redstone* became the test-bed for guidance and major components of the *Jupiter.*

Range is 200-300 miles although one unit with reduced warhead is reported to have traveled a distance of 350 miles. Powerplant is a North American liquid oxygen-alcohol engine yielding a thrust of 75,000 pounds. This powerplant is considered the most proven of U.S. liquid rockets.

Operational status for this medium-range missile is expected soon. The first *Redstone*-equipped unit, the 217th Field Artillery Missile Battalion, was activated and is being formed at Redstone Arsenal. The first Army Ordnance Corps company organized for the specific purpose of providing supply and maintenance for the *Redstone* long-range rocket has been activated at Redstone Arsenal. It is the 630th Ordnance Company and is assigned to the Army Ballistic Missile Agency. It supports the 217th Field Artillery Missile Battalion which was the first Army unit formed to handle the missile. The 630th's support mission includes responsibility for supply and maintenance of warheads, fuels, the missile and other items of the missile system. The Ordnance Corp's most advance class of officer trainees concluded a one week course of study at the Ordnance Guided Missile School, Redstone Arsenal, in November.

The *Redstone* missile is designed for rough handling and typical field service transportation and environment. Chrysler Corp. has been praised in its effort to make the *Redstone* a most reliable weapon while encumbered with the large amount of complex systems and wiring that make up this missile. Production output and amount of money allocated for the program has not been revealed. It is the largest and most potent of the operational U.S. missiles.

The missile is launched vertically from relatively light portable launching platforms and travels toward its target on a ballistic path. The warhead separates from the missile proper and continues to the target stabilized by four small fins. Warhead compartment will accommodate either conventional or atomic payloads. The *Redstone* recently supplied the major impetus for establishing a new distance record for rocket flight. A modified *Redstone* was used as the first stage of a three-stage assembly known as the *Jupiter C.* The *Redstone* burned out, separated and fell into the sea approximately 100 miles from the launching site. The final stage of the configuration fell into the Atlantic 3000 miles from the pad at Patrick.

The Guided Missile Development Division, under Dr. Wernher von Braun, drew nationwide recognition for its competence in developing the *Redstone* missile. In February 1956 the personnel and facilities of this division were transferred to the new Army Ballistic Missile Agency, specifically established for the expedited prosecution of a program to put the ballistic missile in operational status as rapidly as possible. The *Redstone* is a product of cooperative effort between the Army and private industry, and exemplifies the state of the art in missile development that exists today.

Dr. von Braun, in a recent article

Monitor of aggression . . . giant rocket, Army's REDSTONE, 300-mile missile has just rolled off the assembly line of Chrysler Corporation's Missile Operations. Note the dollies on fixed rail lines, two for warhead and two for engine indicating assembly sequence.

REDSTONE test vehicle for the Intermediate Range Ballistic Missile, JUPITER, illustrates Army step-by-step development philosophy.

Even the big boys fly. Here, REDSTONE missile is shown being eased aboard AF Globemaster for air-freighting to Patrick Air Force Base.

on the philosophy employed in the development of ballistic missiles, stated: "The Army has pursued a minimum-risk program in the development of the *Redstone* and *Jupiter* ballistic missiles which provides optimum development and performance.

"The Army's *Redstone* and *Jupiter* missile programs are being handled by a closely-knit and tightly integrated team with many years of experience in the ballistic missile field. This team consists of experienced scientists and engineers of virtually every field involved in this new art. The need for utmost flexibility during the research and development firing period governs our design philosophy. All the guided missile experience to date, including that on the *Redstone*, indicates that this procedure is an effective and economical one for guided missiles.

Mighty REDSTONE thunders towards stratosphere. Missile is development of famous von Braun team at Army's Redstone Arsenal.

Army Chief of Research and Development, Lt. Gen. James H. Gavin, stands beside model of REDSTONE missile, his hand indicating the warhead. This missile is now in production at Chrysler Corp. and is in the process of being weaponized by Redstone Arsenal.

U.S. Army's JUPITER

The *Jupiter* IRBM has scored the first victory in the controversial IRBM evaluation program. After two failures earlier this year, the Army has succeeded in firing a *Jupiter* missile to the limit of its designed range or approximately 1,500 miles. The instrumented vehicle attained an altitude of approximately 250 to 300 miles.

Trouble with the first two *Jupiter* test vehicles apparently stemmed from sloshing fuel. Fix was made by incorporating *Thor* anti-slosh devices in fuel tanks. Anti-slosh devices are reported to be a set of baffles proof-tested in earlier missile flights with similar tank configuration. These were designed to hold fuel slosh to a minimum without interrupting fuel flow. The first two *Jupiter* test vehicles exploded prior to scheduled burnout.

The Army also took steps to eliminate two other potential weak spots in the third *Jupiter*. It removed a gust sensing indicator mounted on a forward probe and installed a heat blanket shield at the base of the missile to prevent eddies of exhaust flame from burning out the control wiring. *Jupiter* has also solved its gas generator exhaust problems by shifting from hydrogen peroxide decomposition to hot gas drive for auxiliary power turbine. The hot gas drive burns missile propellants for operation of the power turbine.

The *Jupiter* carried instrumentation in place of the warhead it would normally carry in operational use. It was controlled by a preprogrammed auto-pilot which held its attitude during flight to the programmed course. Later vehicles will be equipped with a full-fledged guidance system which will include computing as well as sensing elements.

North American Aviation is supplying the same rocket engine for the *Jupiter* that is used by the *Thor*. The similarity of the two missiles will become even more pronounced if the expected airframe switch for the *Jupiter* materializes.

The engine for the *Jupiter* is reported to develop approximately 135,000 lbs. thrust. The missile is approximately 60 ft. in length and 8 ft. in diameter. Separation of the warhead is expected as a performance feature as a result of *Redstone* development.

The Defense Department has removed the Air Force from its funding responsibility for the IRBM program until a decision is made between the *Jupiter* and the *Thor*. Current plans now call for Defense to transfer a portion of its emergency R&D funds to the Army sometime in August to allow the *Jupiter* program to continue. Despite the funding deviation from the Wilson memo, Defense officials emphasized that there is no change in the basic roles and missions assignment.

USAF and Army ballistic missile experts met at the Army's Redstone Arsenal last month for a technical information exchange on the *Jupiter* and *Thor* programs. Nineteen USAF missile experts accompanied Maj. Gen. Bernard A. Schriever, director of ARDC's Ballistic Missile Division, to the Huntsville, Ala., facility. The presentation highlighted the programs achieved by the agency in the development of the *Jupiter*. A joint release stated "The Army is continuing this development under authority of the Secretary of Defense, who has determined that operational employment of the IRBM will be the responsibility of the Air Force." The statement further asserted: "The sole interest of both uniformed services is to provide the best IRBM at the earliest practicable date in the urgent interest of national defense. It is to achieve this objective that we have committed all resources, manpower, facilities and funds for the purpose. Out of this joint effort will emerge the weapons systems determined essential to the security of our country." This statement, coupled with the recent successful firing of the *Jupiter*, lends support to the Army's contention that it can have *Jupiter* operational before *Thor*. It is felt in some quarters that the *Jupiter* has taken a wide lead in the development race. At the same time Air Force officials express doubt that the IRBM will be ready for operational units inside of a year.

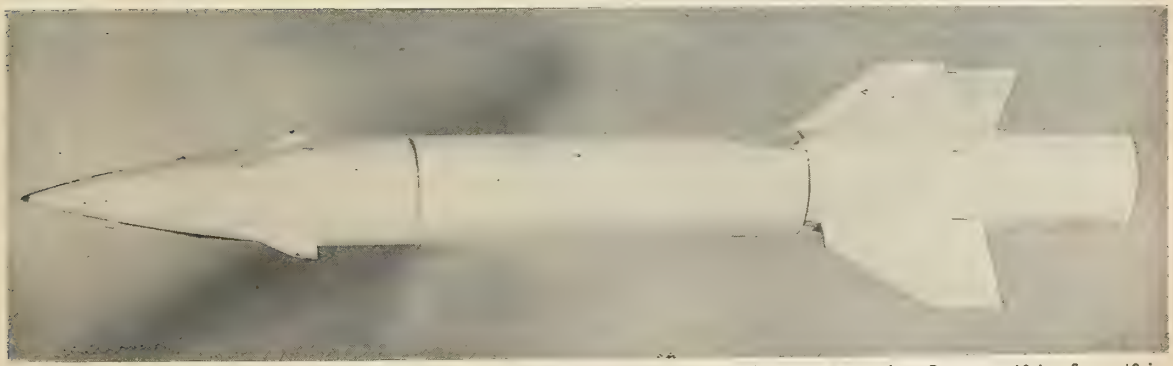
STATUS: research & development

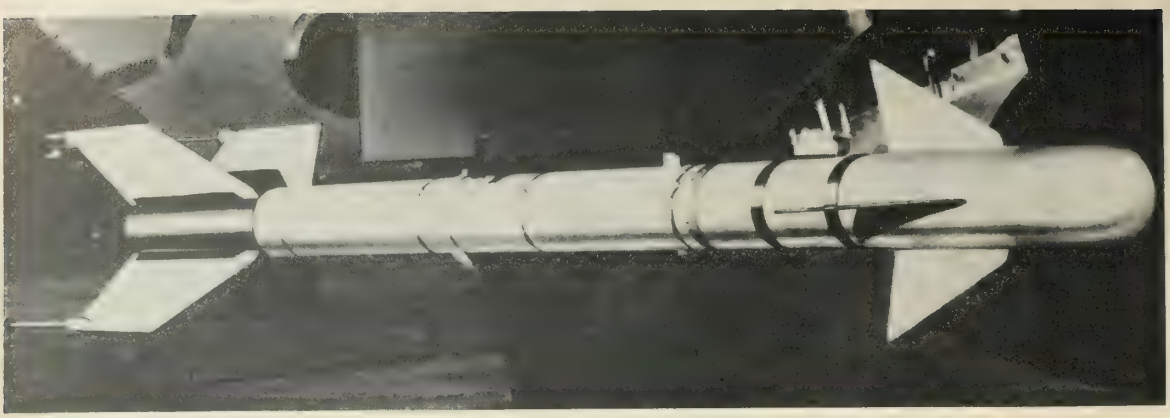
REMARKS:
thrust control system designed and manufactured by Servo-mechanism

U.S. Navy's
CORVUS



Corvus, which is Latin for crow, is being developed by Temco under a $16 million contract. It is an air-to-surface missile for use on carrier-based aircraft. Navy has issued invitations for new carrier-based craft capable of carrying *Corvus.* The only aerodynamic model of *Corvus* recently completed wind tunnel testing at Massachusetts Institute of Technology. Data submitted by Temco to Navy for clearance is reported to be at the bottom of the list as far as releasing it is concerned.

DIAMONDBACK



Diamondback is an air-to-air missile believed to be a successor to the infra-red homing *Sidewinder.* It may be one of the missiles in development now known as *Sidewinder II* or *Sidewinder III.* Increased performance and range over *Sidewinder* is the goal of the *Diamondback* project.

BULLPUP

Navy is now evaluating the *Bullpup* air-to-surface missile and it will soon be introduced into fleet service as a service weapon. Prime contractor of the missile is The Martin Co. and production is underway at the Orlando, Fla. plant. Powerplant is a solid propellant rocket by Aerojet-General. Republic Aviation is working on a guidance system for *Bullpup.* Missile has canard layout with delta and trapezoidal control and stabilizer surfaces. It is 11 feet long and has a diameter of 1 foot. *Bulldog* is a larger and improved version of *Bullpup.*

Manufacturer: Martin Co.; Range: PUP-15,000 ft., DOG-25-30,000 ft.; Speed: PUP-Mach 1.8, DOG-Mach 2; Diameter: 12 in.; Span: 12 in.; Guidance: self-contained navigation system; Powerplant: (1) Aerojet-General; Status: advanced development.

The ultimate in simplicity, Navy's SIDEWINDER air-to-air infrared missile, has less than two dozen moving parts and no more electronic components than an ordinary radio.

U.S. Navy's SIDEWINDER

Sidewinder, Navy's air-to-air infrared homing missile is named after the deadly, fast-striking, desert rattlesnake which habitates the area around China Lake, Calif., where the missile was conceived and developed by the Naval Ordnance Test Station.

Designated AAM-N-7, the *Sidewinder* is operational with TacRon 46 aboard the *USS Randolph* with the 6th fleet in the Mediterranean and FitRon aboard the *USS Bon Homme Richard* with the 7th fleet in the western Pacific. Among the aircraft which are or soon will be equipped with the rocket are the F9F-8, FJ-3, FJ-4, F8U, FD-4, F3-H, F-104, F-100 and F-89.

The missile is a rugged, inexpensive weapon capable of operating against high-performance type aircraft, and can destroy enemy fighters or bombers from sea level to altitudes over 50,000 feet. It needs no complex launching equipment and is highly maneuverable at supersonic speeds. Basically a defensive weapon for the protection of men and ships from attacks by enemy aircraft, *Sidewinder* also will be employed in the air defense of the continental United States.

Because of its simplicity the missile, which has less than two dozen moving parts and no more electronic components than an ordinary radio, requires no specialized training to handle and assemble it effectively. Pilots will require little or no special flight training to effectively use *Sidewinder* in combat.

Sidewinder is 4½ inches in diameter and 9 feet long. It is positioned on the launching rack by three lugs that are slid into place. Four stabilizing fins are located on the aft section. These are about 21 inches long and 8 inches high with a swept-back leading edge 10 inches long. Four canard control fins are located about 11 inches from the missile nose and attached to the body by single pivot points. Swept-back leading edges of the canards are about 11 inches long and the trailing edge is about 6 inches. The base of each fin is about 8 inches long.

The guidance system is passive infra-red and this usually takes the missile up the tail pipe of the enemy aircraft. The guidance has been described as being so accurate as to seek and "kill" flares attached to drone wings without harming the drone itself.

The seeker occupies the first 4 inches of the missile, followed by guidance section; servo is located between control fins, followed by warhead, influence fuse and solid propellant rocket motor. The motor is 75

Ground crewmen attach SIDEWINDER AAM-N-7 to launching rack of F9F-8 COUGAR fighter. No specialized training is required to handle and assemble it effectively.

inches long, has a nozzle 7 inches long with 3-inch inside diameter. Burning time is 2 seconds.

Current kill rate of *Sidewinder* is reported to be 7 out of 10 and this is expected to be improved to a single-shot kill capability of 9 out of 10. Range at high altitude is 11,000 feet and at sea level about 3,500 feet. Contact fuses are located at tips of control surfaces. The influence fuse takes care of a miss situation detonating the missile which is lethal within 35 feet.

Sidewinder's seeker is operative from the moment of the launcher aircraft's takeoff. Control surfaces are stabilized by a small bucket-type wheel turning at a very high speed.

The idea for *Sidewinder* came from Dr. William B. McLean, technical director of NOTS in 1949. Development at NOTS included structure, aerodynamic configuration, infrared guidance, rocket motor, pilot presentation, aircraft-missile umbilical connection, launcher and test devices. All this was under surveillance of Bureau of Ordnance. Bureau of Aeronautics was responsible for the launcher and envelope.

Prime contract for *Sidewinder* production is Philco Corp. The company is producing the missile at its Philadelphia plant under a contract totalling approximately $14-million.

Other industrial concerns connected with the program are the Avion Division of the American Car and Foundry Industries at Paramus, N. J., who produced experimental missiles used in the research and development program and General Electric Co. at Utica, N. Y. which has been awarded a production contract amounting to more than $17 million.

Eastman Kodak Co. of Rochester, N. Y. and the Bulova Research and Development Laboratories of Weedside, N. Y. are also involved in the *Sidewinder* program. Eastman is reportedly doing the infra-red work.

Power plants for the missile are of the solid propellant type reported to be supplied by Norris Thermador, Hercules Power and Hunter-Douglas.

Although it is a Navy development, *Sidewinder* will be used by the Air Force. Funds have been allocated in the AF 1958 budget for purchase, presumably for use on the F-104. First firings of *Sidewinder* from the Lockheed fighter were announced a few weeks ago. F-100 and F-89 aircraft are also expected to carry *Sidewinder*.

Advanced models, *Sidewinder II* and *Sidewinder III* are reportedly in test and prototype stages, respectively.

SPECIFIC DATA:

MANUFACTURER:	Philco Corp., General Electric Co.
MISSION:	air-to-air
RANGE:	18,000 ft.
SPEED:	Mach 2.5
LENGTH:	9 ft.
DIAMETER:	4½ in.
GUIDANCE:	infra-red
COST:	$1,000; some reports as low as $800
POWERPLANT:	solid propellant rocket
STATUS:	service

Bird is 4½ inches in diameter and 9 feet long. Current kill rate is 7 out of 10.

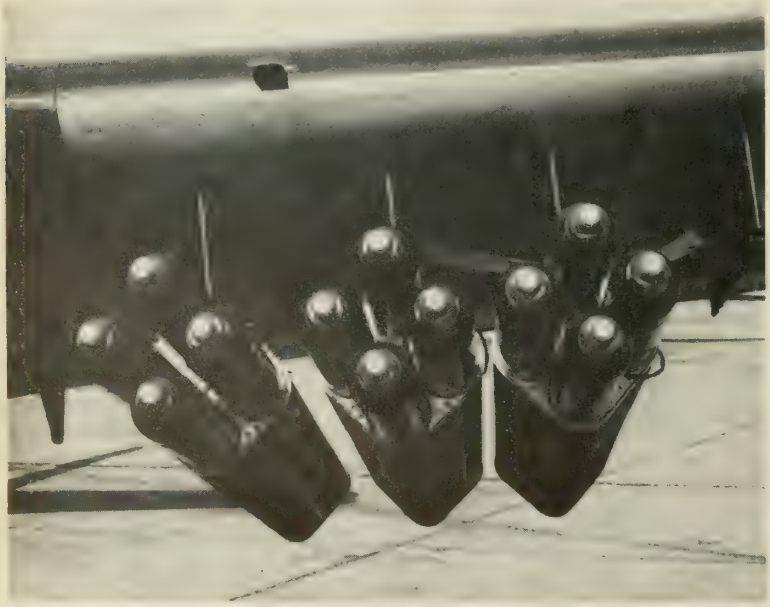
SIDEWINDER was developed by the Naval Ordnance Test Station at China Lake, California. Now operational with the 6th fleet in Mediterranean and 7th fleet in the western pacific.

U.S. Navy's ZUNI

Replacing Navy's World War II high velocity aircraft rocket is the recently announced *Zuni*, named after the Pueblo Indian tribe of Western New Mexico.

Zuni is a 5-inch rocket, 110 inches long and weighing 107 pounds. It has jet operated folding fins, a feature that allows an aircraft to carry four times as many rockets as they could *HVAR's*. *Zuni* carries a variety of warheads and fusing systems.

This folding fin, solid propelled weapon has been extensively tested by both BuOrd and the Fleet Operational Development Board, and is now approved for operational use. It has twice the velocity of the HVAR of World War II fame.



The new rocket will be used on high-performance fighter and attack-type aircraft for both air-to-air and air-to-ground firing. As an air-to-ground weapon it will be highly effective against tanks, pillboxes, gun emplacements, trains, ammunition and fuel dumps and small ships. Its high velocity and short time to target promise a high kill potential in air-to-air combat.

The *Zuni* launcher, mounted on the aircraft's wing, holds four rockets and is used for transporting and storing the rockets as well as launching. Launchers are jettisoned after firing.

The elimination of the normal packing case is expected to result in considerable time savings. *Zuni* is also designed for air-to-surface applications.

The unguided rocket generally has good static stability and reports indicate that *Zuni* is no exception. Detailed performance figures, however, are not yet available. In guided rockets, on the other hand, one must allow for a large displacement of controls to maintain a given flight path or to change direction. With relatively low static stability, they enjoy a high maneuverability rate.

Zuni's solid propellant rocket motor powers it at speeds in the vicinity of Mach 3. Cost of each rocket has been reported as $150. It was developed by the Naval Ordnance Test Station, China Lake, Calif. for the Bureau of Ordnance.

ZUNI is folding fin, solid propellant rocket, designed for fighter and attack-type aircraft, for air-to-air and air-to-surface attack. Expendable launcher holds four rockets.

• • •

SPECIFIC DATA:	-
MISSION:	air-to-air & air-to-surface
SPEED:	Mach 3
WEIGHT:	107 lbs.
LENGTH:	110 in.
DIAMETER:	5 in.
POWERPLANT:	solid propellant rocket
REMARKS:	
STATUS:	Quantity production

REMARKS:
air-to-air, air-to-surface, developed by Naval Ordnance Test Station for Bureau of Ordnance.

Sparrow I is a supersonic air-to-air missile operational in the fleet. It was developed by the Bureau of Aeronautics at the Naval Air Missile Test Center at Point Mugu, Calif., and the Sperry Gyroscope Co.

Described as a powerful deterrent against attack by jet bombers and fighters, it is about 12 feet long, weighs about 300 pounds, and is powered by a solid propellant rocket motor.

Guidance signals deflect the missile's wings and direct it to intercept the target, even under evasive action. The *Sparrow I* weapon system is versatile, permitting effective attacks against high and low altitude targets flying singly or in groups.

Guidance is of the beam-rider type directed by the launching aircraft. The complete system is manufactured by Sperry Gyroscope Co. and the rocket motor is made by Aerojet-General. Speed of *Sparrow I* is about Mach 3 and range is 5 to 8 miles.

McDonnell DEMON armed with a formidable array of SPARROW I air-to-air missiles.

U.S. Navy's SPARROW I

Official designation of *Sparrow I* is AAM-N-2.

The deadly accuracy of the missile has been demonstrated by hundreds of missile launchings against drone targets. Successful attacks have been completed against high speed jet aircraft and against other missiles.

Operational squadrons have been assigned to carriers. Additional carriers of both Atlantic and Pacific fleets, including the super-carrier *Forrestal*, will be equipped with squadrons armed with *Sparrow I*.

Sparrow I contracts of more than $50 million were awarded Sperry for the missile guidance radar and test equipment and for production of the missiles at the Sperry Farragut Co. in Bristol, Tenn.

Sparrow I systems are on the Chance Vought F7U-3M *Cutlass* with fleet units operating both from carriers and shore and with a night-fighter squadron of the Marines employing the Douglas F3D-2M *Skyknight*.

Sparrow II missiles were developed by Douglas presumably for use on the Douglas F5D which was cancelled. The *Sparrow II* has an active homing system with a radar dish behind a blunt nose. Control surfaces are trapezoidal rather than delta-shaped as in *Sparrow I* and *III*. Some reports have been heard that the Royal Canadian Air Force will use *Sparrow II* to replace the *Velvet Glove* missile.

Sparrow III missile is a Raytheon development and has been ordered into production at the Sperry Farragut plant under direction of Raytheon. Retouched photos indicate that *Sparrow II* is about the same size as *Sparrow I*. The Raytheon guidance system is said to be completely automatic in operation. Raytheon has a $60 million production contract for the missile and is reported to be working on two still more advanced models.

SPAN:	2.25 ft. (has smaller tail fins also)
COST:	$10,000
STATUS:	service

REMARKS:

SPARROW-II, officially known as the XAAM-N-3; length is said to be 4.2 ft. with weight 300 lbs.

SPARROW I missile system is combat-ready. Fighters armed with SPARROWs are equipped with airborne guidance gear developed by BuAer and Sperry Gyroscope to direct missiles.

U.S. Navy's TORPEDOES Mark 27, 37, and 43

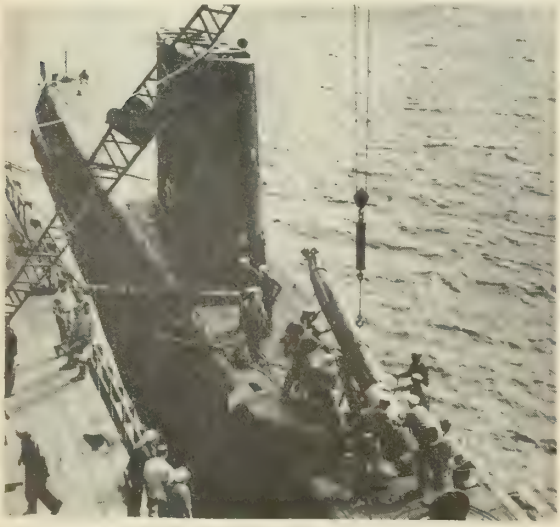
The first modern guided missile was World War II's sonar-guided torpedo. Even though it worked solely underwater, it fit the definition of a guided missile and beat its airborne cousins by some years.

With designations like Mark 27, Mark 37 and Mark 43, World War II and present operational torpedoes have speeds ranging from 20 or 30 knots to 45 knots. Generally speaking, electrically powered torpedoes were slower but gave off no tell-tale wake and were thus more silent. Steam torpedoes or gas generator-turbine powered units reached higher speeds but gave off both visual and audible wakes. Generally speaking, the practical operational range of the torpedo was considered to be 10,000 yards.

The World War II electric torpedo used a conventional lead-acid battery. Silver cell batteries (Zn-alkali-Ag202) are up to six times lighter and five times smaller than lead-acid batteries for the same output. Primary batteries such as the magnesium sea-water-silver chloride are even lighter and smaller and are considered for torpedo use.

For the higher speed, longer range torpedoes, total energy requirements are such that thermal power plants must be used. A wide variation in performance is achievable, depending upon the propellant combination. Because of their relatively high performance and their potentially wakeless exhaust products, hydrogen peroxide-hydrocarbon systems have been widely used.

Use of either carried fresh water diluent or free sea water diluent is necessary in turbine propulsion systems in order to decrease the operating temperatures. The use of sea water, although significantly increasing the performance per unit of carried expendables, poses serious salt problems.



For reciprocating engine power plants, no diluent is necessary. Copious quantities of sea water are required, however, to cool critical engine parts.

However, underwater warfare appears on the verge of a technological revolution. Noisy, bubble-forming cavitation, a major problem of high-speed underwater flight, appears about to be overcome by more close emulation of the hydrodynamics of a fish. Propulsion systems under study now include not only the gas turbine but hydroducts (ramjets) and pure, conventional rockets as well. An Aerojet-General test torpedo utilizing one of the latter propulsion systems has done 155 knots underwater in captive runs. At speeds of this order, the fact that it is noisy and can be readily detected by conventional sound gear diminishes in importance. Even if the torpedo is detected, the vessel attacked would scarcely have adequate time for evasive action.

One problem, however, of large noise levels emanating from the torpedo itself is that of interference with the missile's own sound-based guidance system. However, recently highly successful work with the detectability of sounds in the very low frequency ranges may make it possible to tune guidance gear so that it will ignore its own self-made noise.

One view of the torpedo of tomorrow might be as follows: Its body will be made of magnesium, plated to provide a smooth high gloss finish. Its detection and homing gear will be acoustic; will have a range of well over 100 miles if necessary; and will concentrate in the ultra-low frequency ranges. Its speed may be anywhere from 150 knots upwards. Its propulsion system will consist of a hydroduct (ramjet) whose "combustion" products are solubles, thus leaving no visible wake. Hydrodynamically, it will be near-perfect, providing means of pressure equalization (boundary layer control), perhaps with ducts to feed in or draw off water as necessary. Its range may be anywhere from ten to several hundred miles. Its warhead will be either nuclear or with conventional explosives.

In addition, there are several projects now under way—some in the feasibility study stages; others under actual development—that involve transitional concepts where the missile starts out underwater and then becomes airborne, or vice versa.

U.S. Navy rightly can claim to be the producer of the first guided missile. Future underwater missiles may have speed of 150 knots.

U.S. Navy's TERRIER & TARTAR

A slim, needle nose weapon, *Terrier* is designed to intercept aircraft at longer range and higher altitudes than anti-aircraft guns, and under all weather conditions. A contract for about $29 million has been awarded to Convair at Pomona, Calif., for production of guidance and control units of the missile. Convair, prime contractor, participated in the engineering of *Terrier,* which was developed for the Bureau of Ordnance under technical direction of the Applied Physics Laboratory, Johns Hopkins University.

Now in operational use, *Terrier* is installed on the cruisers *USS Boston, USS Canberra,* destroyer *USS Gyatt* and will be used on many other destroyer-frigate type vessels.

The "coke handling" system for launching *Terrier* is a product of Northern Ordnance, Inc., Minneapolis. Solid propellant power plant is by Aerojet General. It is launched by a booster and is beam-rider guided.

Terrier is 13 feet long, 27 feet long with booster. It is about one foot in diameter, has a fin span of 4 feet, weighs about 3,300 pounds. Speed is 1,500 miles per hour, range about 20 miles, ceiling 60,000 feet. Cost is about $62,000. Effectiveness has been reported at 80 per cent.

Terrier II is reported to be twice the size of *Terrier I* and will have radar homing guidance to supplement shipboard beam-rider direction. Radome of Corning Glass Works Pyroceram will withstand temperatures of 2,400°F.

• • •

SPECIFIC DATA:

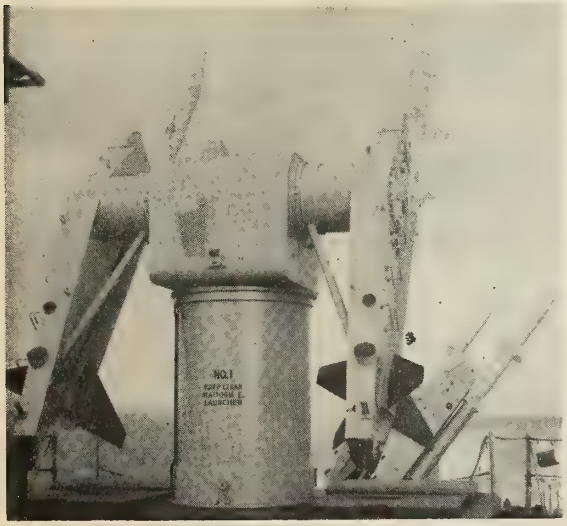
MANUFACTURER:	Convair
MISSION:	Surface-to-air
RANGE:	20m
SPEED:	Mach 2.5
LENGTH:	15 ft.
DIAMETER:	1 ft.
SPAN:	4.1 ft.
GUIDANCE:	Reeves beamrider
POWERPLANT:	(1) Aerojet General SPR (1) Aerojet General SPR booster (14 ft.)
ALTITUDE:	60,000 ft.
STATUS:	early production

REMARKS: surface/ship-to-air, anti-aircraft missile. Replacing TERRIER I; now in use on cruisers and one destroyer—will be installed on 4 more ships by 1959, 13 by 1960 and 22 by 1961, when it is replaced by TARTAR.

Tartar is a surface-to-air guided missile about three-fourths the size of *Terrier.* Prime contractor is Convair and the solid propellant rocket motor is supplied by Allegany Ballistics. *Tartar* will be used on destroyers and other small vessels.

Rear Adm. John H. Sides has said that *Tartar* will also be used in secondary batteries of large ships. He reported that it outperforms the original *Terrier* and will replace five-inch batteries. Adm. A. A. Burke, Chief of Naval Operations, said *Tartar* should be cheaper than *Terrier.*

Convair's Pomona, Calif., plant has the *Tartar* contract for engineering and production under Bureau of Ordnance. In March this year contracts were let for construction of eight destroyers which will be equipped with the missile. Bureau of Ordnance has asked for $32 million in fiscal 1958 for production of the *Tartar.* This is $19 million more than received this year.



In recent hearings before the House Defense Appropriations Subcommittee Rear Adm. Frederic Withington, Chief of Bureau of Ordnance said, "I am committed to have this weapon completely ready for destroyers in the 1957 building program. As I have told the committee, this is a considerable gamble. I hope we will make it but I cannot guarantee it."

• • •

SPECIFIC DATA:

MANUFACTURER:	Convair
MISSION:	surface-to-air
GUIDANCE:	beamrider with homing head
STATUS:	development
POWER PLANT:	(1) SPR

REMARKS: surface ship-to-air, anti-aircraft missile; essentially a refined and improved TERRIER, smaller in size; scheduled to be standard armament on destroyers and secondary armament on capital ships by 1961.

The deadly Terrier, supersonic Navy surface-to-air missile was fired experimentally in November 1954 from the Navy's USS Mississippi.

U.S. Navy's REGULUS I

Regulus I is the first in a series of surface-to-surface missiles developed and manufactured by Chance Vought. Its name is taken from a star in the constellation Leo. Regulus also was a popular name in the middle ages for a snake that was supposed to kill by its hiss.

The *Regulus I* resembles a swept-wing jet fighter, 33 feet long, span of 21 feet, diameter about 4½ feet. Take-off weight is 14,520 pounds, speed is about 600 miles an hour and range is 600 miles maximum.

Designated SSM-N-8, the missile was developed in 1948 by Chance Vought under the sponsorship of the Bureau of Aeronautics. It was designed for launching from submarines, surface ships, and shore bases. Launching equipment can be installed in a short period of time on several types of vessels at relatively low cost with only slight modification to the ship.

Tactically it will be used by Marines against appropriate land targets.

Although the assault missile and certain other configurations will employ a drone version of *Regulus I*, tactical employment will also include those techniques and guidance systems associated with the operation of all-weather, distantly controlled guided missiles. This makes it possible to utilize *Regulus I* in various ways without the expense and effort of designing and procuring a separate one for each function.

At the end of 1956 Chance Vought's Dallas plant had orders totaling $26 million for production of *Regulus I* which had been in service as the Navy's first operational attack missile since 1955.

The non-recoverable version of *Regulus I* is capable of delivering a nuclear warhead over a range of hundreds of miles guided by a built-in electronic brain built and developed by Stavit Engineering and Advance Industries, Inc. The recoverable version, equipped with a retractable landing gear, flies pilotless missions and lands intact. As many as 16 flights have been made by a single *Regulus I*. The drone designation is KDU-1.

Powerplant of *Regulus I* is an Allison J33-A-18A turbojet delivering

REGULUS I on a test flight. It travels at about 600 miles an hour with a 600 mile range. Successful flights with wing pods have been made extending range to a possible 1000 miles.

4,600 pounds of thrust. The missile is launched by two Aerojet-General solid propellant 1,000-pound thrust ATO rockets or by means of a steam-driven catapult.

Regulus I is directed by a command guidance system, parts of which are manufactured by Bendix, Ultrasonics Corp., Sperry Gyroscope, Motorola, Inc., and Bell Aircraft.

The subs *Tunny* and *Barbero* carry the *Regulus I* in round watertight hangars on their decks just aft of the conning tower. In a matter of minutes after surfacing, crews can roll out and launch the missile. The sub *Halibut* will have an internal hangar for both *Regulus I* and *Regulus II*. It will be the first nuclear submarine specifically built for missiles.

Airframe subcontractors for *Regulus I are* R. H. Osbrink and Bendix. Subcontractors on the powerplant are Goodrich and Goodyear.

Fuselage of *Regulus I* is cylindrical with heavy gauge skins wrapped on bulkheads, stringers and longerons. Wings consist of cast magnesium outer panels on a conventional built-up center section. Wings fold for shipboard stowage. There is no horizontal tail—both pitch and roll control being exercised through ailavators on the trailing edge of the wing.

Missile is launched from a short rail launcher in which it rests on four slipper fittings. Launching boost is from two rockets which accelerate the missile to flying speed in a little over 2 seconds. Rocket cases and slippers are ejected after launch.

The subs TUNNY and BARBERO carry the REGULUS I in round watertight hangars on their decks just aft of the conning tower. Photos show launching sequence aboard USS TUNNY. Missile is moved from hangar to launch platform, is prepared for firing, and soars skyward leaving clouds of smoke from its solid propellant booster rockets.

Slated for arsenal of the U.S. Fleet next year TALOS can, in addition to its surface-to-air mission, be used against ship and shore installations. Army may use it for air defense.

U.S. Navy's TALOS

Talos, Navy's long-range, surface-to-air missile, will be added to the fleet early in 1958. It will form the major armament of the light cruiser *USS Galveston* now undergoing conversion to a guided-missile cruiser at the Philadelphia shipyard. A year later cruisers *USS Little Rock* and *USS Oklahoma City* will be armed with *Talos* and will rejoin the fleet. The first nuclear-powered cruiser *Long Beach* will also have *Talos* armament.

Talos is capable of delivering a high explosive or nuclear warhead at any altitude that airplanes can fly and far beyond the range of human vision. Originally designed for shipboard installation, *Talos'* great range and accuracy have drawn the interest of Army as ground defense weapons in the Continental Air Defense system.

Production of *Talos* is underway at the Naval Industrial Reserve Ordnance plant, Mishawaka, Ind., operated by Bendix Aviation, for the Bureau of Ordnance. Bendix received a $27 million contract early this year.

The missile is the second to come out of the *Bumblebee* program at the Applied Physics Laboratory for Johns Hopkins University.

Talos is powered by a McDonnell ramjet engine which operates after the missile has been boosted to supersonic speeds by a solid rocket motor. The ramjet using zip fuels is reported to propel the missile at Mach 3.5.

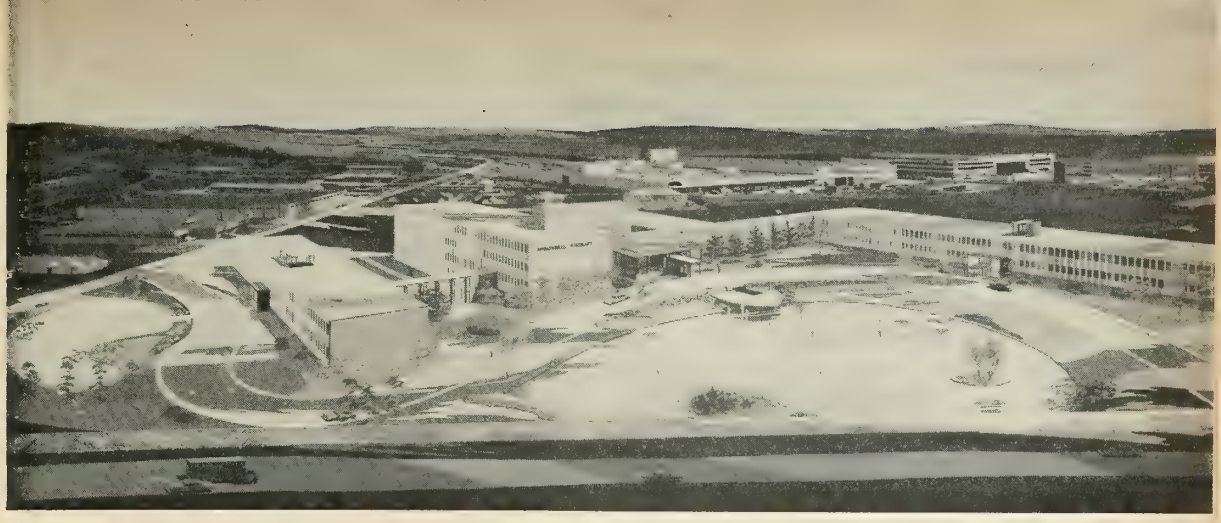
The guidance is a mechanical brain called steering intelligence system which insures great accuracy. When within lethal range of target a proximity fuel detonates the warhead.

Rear Adm. J. H. Sides said "*Talos* is larger than *Terrier* and has longer range. It will reach out into zones now covered by interceptors." The missile is being evaluated at White Sands Proving Ground, N. Mex. In development tests it killed a drone at 25 miles with a direct hit. That was in 1954 and Navy says missile has undergone considerable improvement since.

Talos is essentially a 20-foot hollow tube 30 inches in diameter. Inside the open nose is a blimp-shaped diffuser which channels air past burners producing tremendous thrust. Four maneuverable stubby wings at mid point and four tail fins control its course and stabilize its flight. Fins are said to be made of fiberglass. Those made of magnesium were rejected.

McDonnell, in addition to supplying the ramjet engine, also builds the airframe. Radio Corporation of America is reported to be involved in development of ground and airborne radar beam-rider systems.

Reports early this year have indicated that *Talos* might become the standard antiaircraft missile of NATO. It is known that the British would like to procure the missile for replacing RAF interceptors.



• • •

SPECIFIC DATA:

MANUFACTURER: Bendix Aviation Corp. (prime)
McDonnell Aircraft Corp. (airframe)
MISSION: surface-to-air
SPEED: Mach 4
WEIGHT: 3,000 lbs.
LENGTH: 15 ft.
DIAMETER: 18 in.
SPAN: 4.1 ft.
GUIDANCE: Bendix beamrider plus radar homing
POWERPLANT: (1) McDonnell 18" ramjet
(1) SPR booster
ALTITUDE: 75,000 ft.
GROUND CHECK-OUT: Reeves Instrument
STATUS: limited production for test
REMARKS: surface-to-air, inner-defensive, anti-aircraft missile; land-based version recently transferred from USAF to Army cognizant under Wilson's "roles and missions" decree; future status uncertain in view of Army emphasis on NIKE HERCULES

TALOS, boosted by solid propellant rocket, gathers speed as it roars from launcher. It will lock on target and when within lethal range a proximity fuse detonates the warhead.

U.S. Navy's TRITON

Triton is the third generation of sub-launched surface-to-surface missiles on the drawing boards. It is powered by twin McDonnell ramjets and is in the 1,500-mile range class with speeds of Mach 3.5 and a self guiding system. It is expected to reach 80,000 feet in altitude.

Triton will use zip fuels. Solid booster rockets will launch the missile and push it to supersonic speeds when the ramjets take over. *Triton* is designed to fit *Regulus* launching and storage equipment.

Bureau of Ordnance is asking $2.6 million more than last year for *Triton* development. No figure on last year's sum has been reported.

Like *Talos, Triton* is an outgrowth of the *Bumblebee* program at the Applied Physics Laboratory at Johns Hopkins University. McDonnell is the prime contractor and also supplies the ramjet engines. Bendix has been reported as supplying the fuel control equipment and the inertial guidance system is by Kearfott.

In charge of the *Triton* program at McDonnell is Chief Engineer Ben G. Bromberg. His office is responsible for development and testing of guided and unguided missiles which the company has under contract and to involve new missile designs. McDonnell currently has some 750 engineers in the Missile Engineering Division. This is about 20% of the total number employed by the company. The missile engineers are moving into a new $1 million office building—the first of a series to form an "engineering campus" at the St. Louis facility.

Navy Missile Director Rear Adm. John Clark probably referred to *Triton* when he stressed the need for continued ramjet missile development because of the many problems still facing the ballistic missile before it could become a precision weapon. The ramjet missle, he pointed out, is fully controllable and can be guided in flight.

Dr. Ben Bromberg (second from left), Chief Engineer of McDonnell's Missile Engineering Division, and his staff have TRITON development responsibility. $2.6 million additional '57 funds for TRITON.

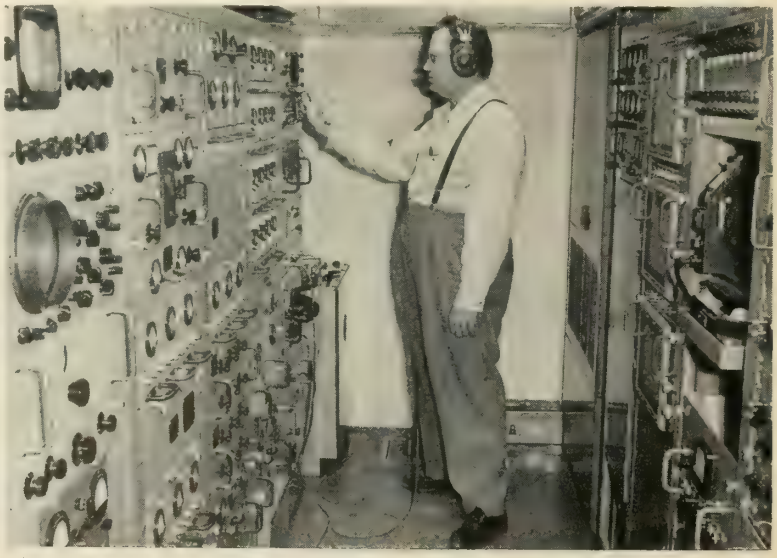
Design engineering section of Missile Engineering Division's new $1 million St. Louis facilities. MED has some 750 engineers. This is about a 20% slice of McDonnell's total engineers employed.

U.S. Navy's REGULUS II

Regulus II is planned as the operational successor to *Regulus I*. Its increased speed and altitude make it a more effective weapon.

The second version of the Chance Vought surface-to-surface missile is designated SSM-N-9 and is designed for launching from a submarine, or ship and may also be used as a land-base weapon. It is 57 feet long, about six feet in diameter and has a wing span of about 20 feet. It may carry a nuclear warhead.

Test models of the missile are powered by the Curtiss-Wright J65 jet engine but production missiles carry the General Electric J79 turbojet—the same engine that powers the supersonic Lockheed F-105, Convair B-58 and Grumman F11F-1.



Regulus II features a fixed canard stabilizer just aft of the nose, swept wings with extremely sharp leading edges and a very large belly air scoop. There is no horizontal tail stabilizer. Test vehicles are equipped with tricycle landing gear for recovery. They are reported to land at about 250 knots on full afterburner with both elevons down.

Navy first showed the *Regulus II* in early March. By that time some 13 test flights had been carried out at Edwards Air Force Base, Calif. Six of these tests were reportedly with the same missile. At last report test models were averaging four flights each.

Rear Adm. John E. Clark said that the range of *Regulus II* is less than the IRBM range of 1500 miles. Most observers say the missile is capable of 1000 miles.

Regulus II test vehicle designed by Chance Vought for the U.S. Navy is recoverable.

Telemeter van used for checking telemeter gear in Regulus II during flights. Regulus II has flown at more than 1½ times the speed of sound and above 50,000 ft.

Reason for the relatively limited range of the *Regulus II* when compared to the 5000-mile range of the similar-sized subsonic *Snark* is that a heavy accent has been placed on speed.

The large air scoop beneath the belly of *Regulus II* has a smaller shovel-shaped inlet located above the engine intake. Air from this small scoop is led through large open ducts built into the fuselage and emptied beneath each wing from slots marked "boundary layer exits." This arrangement is believed to serve as a supersonic fillet to minimize wing-fuselage interference.

Regulus II's altitude has been announced as above 50,000 feet. Speed is Mach 5 to Mach 2.

Compared to *Regulus I*, the later missile is longer by 26 feet, about twice as heavy, and costs about twice as much.

When launched from a surfaced submarine or other ship the missile is boosted by a single, large, solid-propellant motor manufactured by Aerojet General. By the time the missile becomes operational, Navy will have two submarines converted as *Regulus II* launchers.

Firestone Tire and Rubber has a contract for installation of the launching on the subs *Grayback* and *Growler*. Guidance for the *Regulus II* is by Sperry. *Regulus II* is usable from the same ships and submarines that handled *Regulus I*. At present many carriers, four cruisers, in addition to subs, carry *Regulus I*.

Air Force has indicated interest in the *Regulus* missiles as air-to-surface weapons. There have been reports that a *Regulus I* was fired from a B-52. Before firing, the missile was carried in the bomber's big bomb bay.

SPECIFIC DATA:

MANUFACTURER: Chance Vought Aircraft Inc.

MISSION: surface-to-surface aerodynamic cruise

RANGE: 800-1000 mi.

SPEED: Mach 1.5

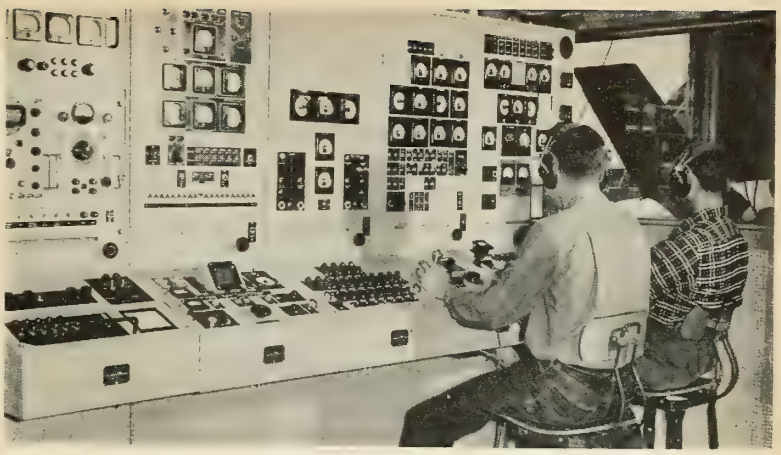
WEIGHT: 12 tons

LENGTH: 57 ft.

DIAMETER: 6 ft.

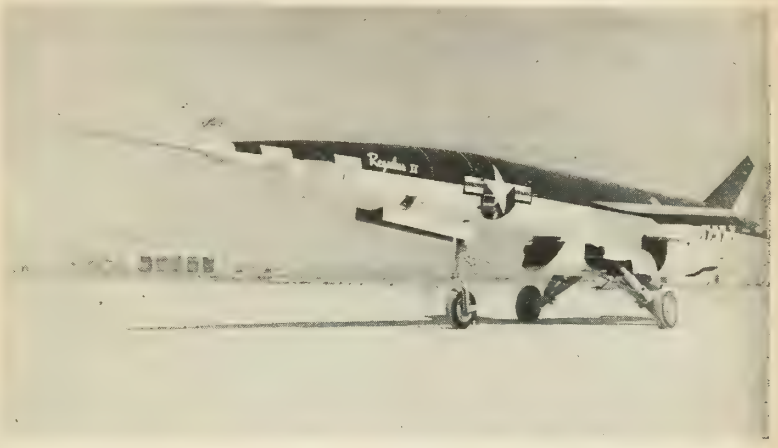
SPAN: 20 ft.

GUIDANCE: radio command by Stavid Engineering Co.



POWERPLANT: first eight a/c-Wright J65s; all others—GE J79s

ALTITUDE: 50,000 ft.



LAUNCHER: (2) Aerojet 4-second solid powder boosters

STATUS: early production

REMARKS: surface-to-surface, air-breathing, aerodynamic tactical missile, shore/ship/submarine launched; Firestone Tire and Rubber Co. Guided Missile Division, Monterey, to design, build, test and install launching system for submarines

Check out of controls for Regulus II is conducted from this Tunny Panel, which is identical to the control system used for Regulus missile in submarine.

Ground view of the supersonic Regulus II at Edwards Air Force Base, California. Missile can carry nuclear warhead and is designed to be launched from subs as well as surface vessels.

Regulus II test vehicle is powered by a J65 turbo jet engine. Later versions will employ the more powerful J79 power plant. This vehicle also employs boundary layer control.

U.S. Navy's POLARIS

Named for the North Star, *Polaris* will be the Navy's first underwater-launched intermediate range ballistic missile. It will be substituted for the *Jupiter* which the Navy was planning to use its ballistic missile system.

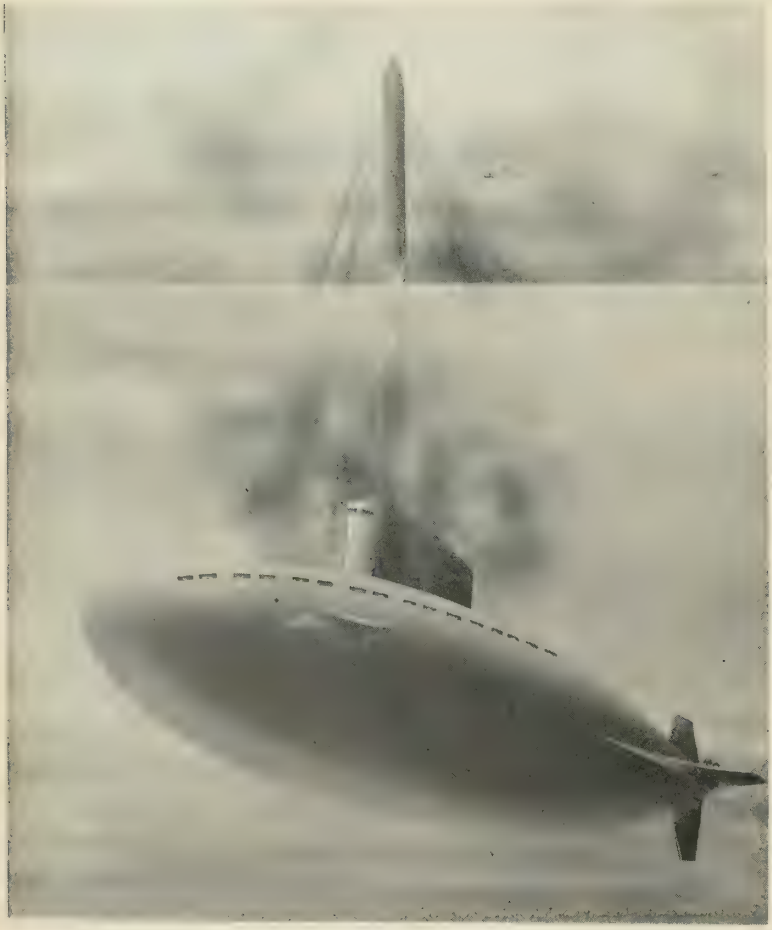
Polaris is described as a stubby weapon with a range of 1,500 miles maximum. One of the reasons mentioned for selection of *Polaris* instead of going along with *Jupiter* was the shipboard handling problem. *Polaris* will have a solid rocket motor instead of the *Jupiter's* liquid motor.

Prime contractor for the *Polaris* is Lockheed Aircraft Corp. at Sunnyvale, Calif. Aerojet-General is working on the rocket and recent reports that the company had fired the largest solid-propellant motor yet, indicates that the company is well along on the project.

Massachusetts Institute of Technology and General Electric are working on design and development for a fire control system for the missile. Loewy-Hydropress Division of Baldwin Lima-Hamilton Corp., has a $2,-million contract to build a ship-motion simulator for use in developing *Polaris*.

Other contractors include Westinghouse-Sunnyvale for design and manufacture of experimental seagoing handling and launching systems including development of various mechanical and electrical systems for launching *Polaris* from subs and surface vessels.

The inertial guidance package for *Polaris* is slated to undergo acceleration and vibration tests at the Supersonic Navy Ordnance Research Track at China Lake, Calif.



Rear Adm. W. F. Raborn, director of the *Polaris* project, said that *Polaris* will be a supporting weapon in future task forces which will be built around the aircraft carrier. Tactical mission would be to beat down fixed-base air and missile defense to pave way for carrier strikes. Infinite number of launching points will make it impossible for the enemy to pre-plot the *Polaris* trajectory.

Admiral Raborn said that the present *Polaris* program provides for a limited number of missiles plus a new nuclear submarine capable of launching the weapon.

Navy has requested $68 million for the missile and related equipment in fiscal 1958.

Some truly sophisticated underwater vessels are being planned by the Navy. These submarines are nuclear-powered guided missile carriers built to launch the solid-propellant, high-punch, intermediate-range *Polaris* Fleet Ballistic Missile. The submarines—possibly two prototypes on order at first—are part of the *Polaris* project.

Possibly the biggest missile and most complex weapons system the Navy has ever attempted, the *Polaris* will be a high-energy solid-propellant stubby 40-50-foot missile approximately 100 inches in diameter. Range is believed to be between 800 and 1500 miles. The atomic warhead in the *Polaris* will be quite sizable, 1000 pounds might be a fair guess.

The POLARIS is described as a stubby missile with a range of 1500 miles. Special submarines using ALBACORE-type hull are understood to be planned for the Navy's fleet ballistic missile. The Polaris can also be launched from surface ships. Lockheed is prime contractor.

U.S. Air Force's MIGHTY MOUSE

For years America's only operational air-to-air rocket was the reliable 2.75 inch, folding fin unguided *Mighty Mouse* or FFAR.

The rocket uses a proximity fuse, and has fins that fold out at launch. Some airplanes, for example the F-89 and F-94C, carry them in wing tip pods to improve dispersion, firing about twelve in a quarter of a second. Other planes, such as the F-86, fire them in single volleys of 24, leaving the aircraft at 200 miles per hour.

The F-89D can carry 104 of these 2.75 rockets and fire them electronically. A T-110 rocket gun has been developed to fire the *Mighty Mouse*.

The principle of the small rocket is that of the shotgun. If enough of them can be fired into a given volume of space, it is almost mathematically impossible that an intruding aircraft or target banner can escape at least one hit even with contact fuses. Since each one packs a wallop equivalent to a 75 mm cannon shell, it is doubtful whether even the largest aircraft could survive a single hit.

FFAR measures 48 inches in length and 18.5 pounds in weight, of which 3.5 pounds is allocated to the warhead. Powered by a double-base solid propellant, it is capable of a maximum velocity of about 2,600 feet per second (Mach 2.7 at altitude), and has a burnout time of about 1.5 seconds. The thrust during this brief period is about 800 to 900 pounds and the acceleration is on the order of 50 gravities. Exact performance specifications remain classified, however.

Aerojet-General Corp., Azusa, Calif., manufactures the rocket motor and ingenious folding fin assembly; Hunter Douglas Aluminum Co., Riverside, Calif., which makes the tubes, and Heintz Manufacturing Co., Philadelphia, which produces the warheads. Colson Corp., Elyria, Ohio, produces rocket motor assemblies.

In the past, components for the 2.75-inch rocket have been produced by at least eight other manufacturers. Manufacturing motors were Tecumseh Products Co., Tecumseh, Mich.; Muncie Gear Works, Muncie, Ind.; Landers, Fary and Clark Co., New Britain, Conn. Tubes were provided by Reynolds Metals Co., Phoenix; Aluminum Company of America at New Kensington, Pa., and Norris Thermador Corp., Los Angeles, while C. D. Cottrell Co., Westerly, R. I., manufactured the warheads.

• • •

SPECIFIC DATA:

MANUFACTURER:	Aerojet General Corp. Hunter Douglas Aluminum Co. Heintz Manufacturing Co. Colson Corp.
MISSION:	air-to-air
VELOCITY:	2,600 ft. per sec. (Mach 2.7 at Altitude)
WEIGHT:	18.5 lbs., 3.5 lbs. warhead
LENGTH:	48 in.
DIAMETER:	2.75 in.
GUIDANCE:	aimed
COST:	$65
STATUS:	service

REMARKS: most available, most ready, most operationally effective air defense weapon available today

Simple missile used by the Air Force is the 2.75" MIGHTY MOUSE, standard weapon for our jet fighters. Missile is easy to handle.

MIGHTY MOUSE packs a wallop equivalent to a 75 mm cannon shell. It is doubtful if the largest aircraft could survive single hit.

U.S. Air Force's FALCON

FALCON aerodynamic configuration is termed pseudo-canard. The forward wings are fixed with steering accomplished by control surfaces placed at trailing edge of stabilizers.

The Hughes GAR-1 *Falcon* is the Air Force's only operational air-to-air missile.

The weapon is smaller than Navy air-to-air weapons, weighing only about 100 pounds and having a range of about five miles. It utilizes a Thiokol solid-propellant motor which produces enormous thrust for a very brief interval, accelerating the missile to a velocity of more than Mach 2.

The *Falcon* is part of a complete weapon system developed by Hughes Aircraft Co. for the Northrop F-89 and Convair F-102A and F-106A interceptors. Approximately 1200 pounds of fire control equipment is carried in the aircraft to support the missile.

Its aerodynamic configuration is termed pseudo-canard. "Pseudo" because although having a typical canard configuration with small forward fins and large aft supporting surfaces, the forward wings are fixed and steering is accomplished by control surfaces hinged to the trailing edge of the stabilizers. A round nose fairs into a cylindrical fuselage which terminates in a boat-tail housing the exhaust nozzle of the rocket motor.

Guidance is by radar impulse generated by the interceptor. The system has all-weather capability and is entirely automatic. It has been reported that Hughes is working on an infra-red version of the *Falcon*. The Air Force is planning, however, to buy the Navy's *Sidewinder IR* air-to-air missile for use with its Lockheed F-104A interceptors.

This will probably mean mixed payloads on a single interceptor. A combination of radar and infra-red guided missiles on the same mission would greatly enhance the possibility of a successful hit. Everything that can be done to out-guess or confuse the enemy's airborne system of countermeasures serves to increase the probability of a successful mission.

Hughes Aircraft Co. says of the *Falcon*: "The GAR-1 has the lethal capacity to stop any bomber dead in its tracks and can do it frequently enough to have resulted in drone bomber targets being one of the major items of project expense. They have been a costly item even though *Falcon* test missiles carry payloads of telemetric equipment rather than warheads."

Cost of the GAR-1 was estimated at $19,000 a copy last year, but it was expected that the cost would drop. Early this year, Hughes announced the GAR-1D *Falcon* which incorporates aerodynamic improvements and can reach greater altitudes than the earlier model.

• • •

SPECIFIC DATA:

MANUFACTURER:	Hughes Aircraft Co.
MISSION:	air-to-air
RANGE:	about five mi.
VELOCITY:	Mach 2 plus
WEIGHT:	(take-off) about 110 lbs.
LENGTH:	77.8 in.
SPAN:	20 in.
PROPULSION:	Thiokol SPR motor 6,000 lbs. thrust

The air-to-air FALCON is the smallest guided missile in production. Slightly over 6 feet in length and weighing 110 pounds, it is powered by a Thiokol solid propellant propulsion unit. GAR-1D FALCON (above) incorporates aerodynamic improvements over earlier model.

U.S. Air Force's BOMARC

Most potent of all air-defense missiles now in advanced development is the IM-99 *Bomarc* pilotless interceptor. Boeing Airplane Co. is developing and producing the weapon for the Air Force.

Unlike the *Nike* and *Terrier* missiles, which are "point" defense weapons, the *Bomarc* is an "area" defense weapon. Its maximum capability may only be realized when the Air Force places the gigantic SAGE information gathering and computing system in full operation.

The Boeing weapon is powered by a pair of Marquardt ramjet engines plus an Aerojet liquid-propellant booster mounted in the tail. It has a gross weight of 15,000 pounds and an estimated range of 200-300 miles. Range may be increased through the use of high-energy synthetic fuels like pentaborane.

Bomarc takes off in a vertical attitude on the thrust of its booster rocket and climbs at supersonic speeds until the ramjets ignite. This occurs before booster burnout, so the total acceleration of the weapon climbs sharply as the upward flight progresses. At its programmed altitude of about 60,000 feet, the missile levels off sharply and proceeds toward its target at speeds in excess of Mach 2.5.

Boeing was awarded a production contract for the *Bomarc* IM-99 interceptor missile on May 16. The initial production contract was for $7,109,195.

Bomarc was revealed as a long-range ground-to-air interceptor missile designed to operate at "extreme" altitudes and supersonic speeds, with outstanding range characteristics.

In a series of successful firings against high-flying "drone" airplanes over the Atlantic Ocean, the *Bomarc* has proved itself an excellent interceptor weapon, according to the Air Force.

Bomarc will be operated by the Air Defense Command from bases where its range capabilities may be fully utilized. Because of its range, the IM-99 is known as an "area defense weapon" as opposed to short-range anti-aircraft missiles known as "point defense weapons."

The new missile is launched vertically by a liquid fuel rocket engine When it reaches a speed suitable for ramjet operation, the rocket cuts out as twin ramjet engines take over to provide supersonic cruise flight. The ramjets are slung on struts beneath the slim, cylindrical *Bomarc* fuselage.

Design of the *Bomarc* missile is based on technical background acquired in Boeing's "GAPA" (Ground to Air Pilotless Aircraft) program of the late '40s. These early missiles, of which 112 were test-fired, ranged up to 16 feet in length and reached speeds of 1500 miles an hour. Their operating altitudes ranged from 6,000 to 80,000 feet.

Speeds and altitudes of the *Bomarc* have not been officially revealed by the Air Force. Armament of the 15,000 pound weapon is described as a "high explosive warhead".

Individual IM-99 flights have been carried out since early autumn 1952. Piloted airplanes fitted with *Bomarc* electronic guidance system components have also been used in the test program, with the pilot cutting out the guidance system and pulling away from the collision course as the *Bomarc*-guided plane closed in on its target.

These extensive tests provided proof of components and supplied background for recent firings in which the Boeing IM-99 missiles were operated as part of an integrate weapon system, seeking out and intercepting "drone" bombers far out over the Atlantic.

The *Bomarc* missile is being assembled in Seattle. More than 70 per cent of the missile is subcontracted.

• • •

SPECIFIC DATA:

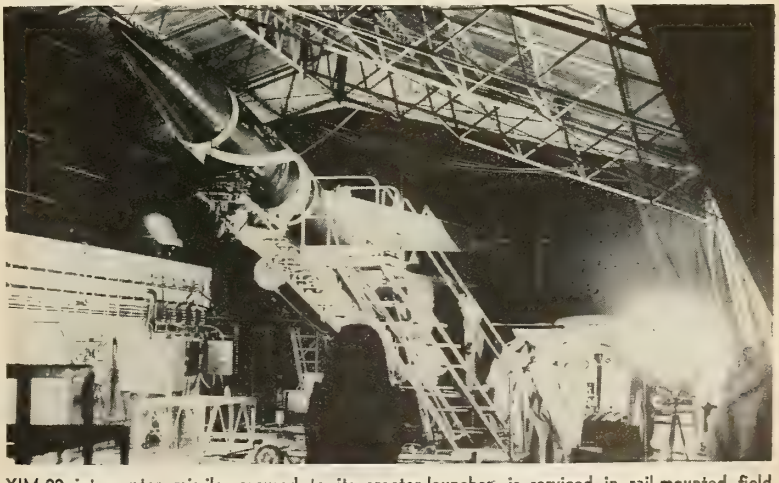
MANUFACTURER:	Boeing Airplane Co.
MISSION:	Surface-to-air
RANGE:	200-300-mi.
SPEED:	Mach 2.5-3

BOMARC, trailing flame from its Aerojet liquid propellant booster engine, leaves launch pad at Patrick Air Force Base, Fla.

WEIGHT:	15,000 lbs.
LENGTH:	46 ft. 8 in.
DIAMETER:	3 ft.
SPAN:	18 ft.-2 ft.

GUIDANCE: SAGE programmed, with radar homing (developed by Westinghouse Air Arm)

POWERPLANT: (2) Marquardt ramjets-28 in. (1) Aerojet General LPR booster



ALTITUDE: over 60,000 ft.

GROUND CONTROL: Remington Rand ERA 1103 computer system

GROUND ALIGNMENT AND CHECK-OUT: test equipment "GO-NO-GO" by Farnsworth Electronics

STATUS: quantity production, for IM-99

REMARKS: surface-to-air, pilotless, aerodynamic cruise interceptor missile. XIM-99 is experimental missile; YIM-99 is service model to be tested by Air Force.

XIM-99 interceptor missile, secured to its erector-launcher, is serviced in rail-mounted field shed in preparation for launching. XIM-99 flights have been made since autumn 1952.

U.S. Air Force's RASCAL

The GAM-63 *Rascal* is a liquid-propelled air-to-surface rocket missile under development for the Air Force by the Guided Missiles Division of Bell Aircraft Corp.

Purpose of weapons like the *Rascal* is to permit bombers to stand off from their targets when delivering nuclear weapons in order to avoid lethal combinations of defending interceptors and anti-aircraft missiles in the target area.

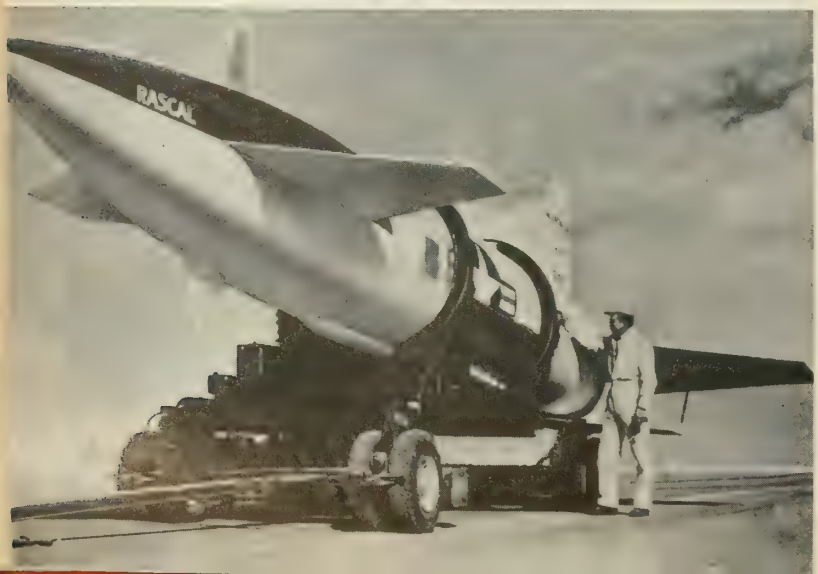
Rascal is undergoing flight testing against simulated targets at Holloman Air Development Center, New Mexico, where it has been launched from B-47, B-36 and B-50 bombers.

The division has made continued refinements in the *Rascal's* powerplants, including the rocket thrust chambers, turbine pump, propellant valves and propellant tanks.

More than 50 rocket propellants have been evaluated in the company's laboratories during the last three years and more than 15,000 rocket thrust chamber runs have been conducted in the more than 50 test cells located at the Wheatfield plant and the nearby Bell Test Center (Air Force Plant No. 38).

An estimated 350,000 pounds of oxidizer and 100,000 pounds of fuel are consumed in these evaluation and production tests each month and the consumption is on the increase.

Nineteen of the division's test cells can be used for environmental testing of thrust chambers and complete rocket engines, with temperatures ranging from minus 65 degrees to plus 287 degrees Fahrenheit.



Rocket engineers have designed and developed rocket engines for five guided missiles, one of which already is operational, and are engaged in designing more powerful rocket powerplants for other military missiles and weapons systems.

Range of the *Rascal* is generally estimated at 100 miles. It utilizes a three-chambered Bell liquid-propellant rocket engine which can accelerate it to speeds of approximately Mach 1.5.

The project came under fire in the report issued by Rep. George Mahon's (D-Tex.) House Defense Appropriations Subcommittee this spring. "Investigations carried out by the Committee Staff have indicated that a reduction in the so-called 'Rascal' program is justified, and the Defense Department agrees that this particular missile is in the marginal area," the report stated.

STATUS:	development

REMARKS:
40 built for test; under product improvement program; Bell awarded $22 million AMC contracts 1/29/57 for continued R&D; strategic air-to-surface.

U.S. Air Force's MATADOR

First of the Air Force's missiles to reach operational status is the TM-61 *Matador* surface-to-surface missile. It is manufactured by The Martin Co., Baltimore, and is powered by an Allison J33 turbojet engine. It can haul a 3,000-pound warhead more than 600 miles at high subsonic speeds and at altitudes of more than 35,000 feet.

The Air Force's first wing of *Matador* missiles is now operational in Germany as part of the Twelfth Tactical Air Force. It is designated the 701st Tactical Missile Wing and consists of three groups located at Bitburg Air Base, Hahn Air Base and Sembach Air Base, Germany. Each group has a tactical missile squadron responsible for actual preparation and launching of the weapon, plus a communication and guidance squadron and a support squadron.

One of the most difficult problems in operational missile units is that of sustaining the unit's combat proficiency at a high level without daily, weekly or even monthly firings. Even if there were space available for such training in Europe, the cost would be prohibitive since each *Matador*, plus its Thiokol solid-propellant booster, costs approximately $100,000.

USAF has developed an inexpensive technique for frequent and thorough tests without expenditure of the *Matador* weapons. This involves the use of a T-33 jet equipped with a Matador-type guidance system. The T-33 simulates the *Matador*, with the pilot responding to visual and audio signals—but no verbal communication—from the ground controller. Just like the missile, the manned aircraft is led through the various phases of a mission, including warhead arming, predumping procedure and simulated dumping on target. On a single flight, a T-33 assigned to the 701st Tactical Missile Wing may execute as many as three simulated *Matador* flights.

The Air Force recognizes that simulated flights, despite their great importance in maintaining proficiency, are not the whole answer. Therefore, the launching teams of the 701st are scheduled to make one actual firing each year at the firing range in Libya managed by the 17th Air Force at Wheelus AFB, near Tripoli.

There are 36 launching teams in the wing. Three versions of the *Matador* have developed to date. The first, TM-61A, was equipped with a single MSQ radar guidance system which requires line-of-sight communication with the missile at all times in order to effect positive control. The 701st has a network of radar tracking stations in Germany to keep tabs on the missile and inform the ground controller of its course and position at all times.

All squadrons of the 701st have now been converted to the TM-61C, which uses in addition to the MSQ system, the so-called "Shanicle" system. Though no details of the system were released by the Air Force, it is believed that "Shanicle" is the first known use of the "HYPERBOLIC grid system." This involves the creation of a grid pattern of radio waves by two separate transmitters.

The missile is pre-programmed to follow a set sequence of augmented and diminished signals across the pattern to target itself. This has the advantage of eliminating the possibility of human error on the part of the ground controller as well as providing positive control over much greater range than the line-of-sight MSQ, but it is not clear to what extent Shanicle might be subject to enemy jamming.

Latest version of the *Matador* is the TM-61B. This is several feet longer than the A and C models and has a clipped wing. It is said to have greater range as well as an improved guidance system requiring no assistance from the ground once the missile is launched. This suggests a number of guidance systems, such as inertial, celestial, a combination of both or a radar transmitter within the missile to determine position.

• • •

MATADOR (TM-61A and C)—
SPECIFIC DATA:

MANUFACTURER:	Martin Co.
RANGE:	more than 600 mi.
VELOCITY:	high subsonic
LENGTH:	39 ft., 8 in.
HEIGHT:	9 ft., 9 in.
WINGSPAN:	27 ft., 10 in.

GUIDANCE: MSQ radar control, first used in Korea to direct fighter-bomber strikes. Also, on C model, the Shanicle system.

ALTITUDE:	more than 35,000 ft.

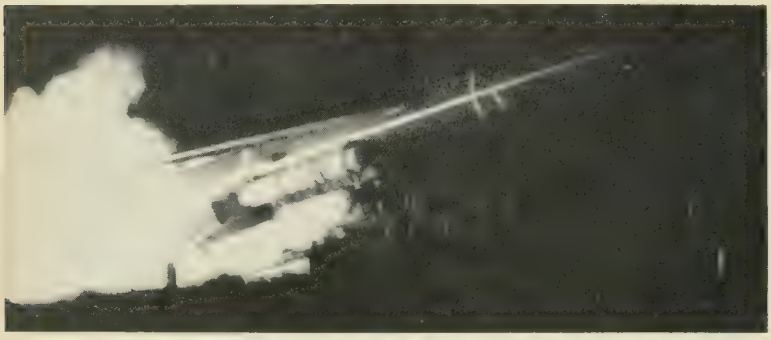
PROPULSION: Booster; Thiokol solid-propellant rocket; 52,000 pounds thrust for two seconds Sustainer; Allison J33 turbojet of 46,600 lbs. thrust.

PAYLOAD:	3,000 lbs.
STATUS:	service

MATADOR B (TM-61B)—
SPECIFIC DATA:

MISSION:	surface-to-surface aerodynamic cruise
RANGE:	over 600 mi.
SPEED:	Mach 0.9
WEIGHT:	13,800 lbs.
LENGTH:	45 ft. 10 in.
DIAMETER:	54 in.
SPAN:	28 ft. 9.5 in.
HEIGHT:	9 ft. 9 in.

GUIDANCE: radar; celestial (?); inertial-depending on model and modification



POWERPLANT:	Improved Allison J33 (4,600 lbs.) Booster Thiokol SPR, 52,000 lbs.
ALTITUDE:	45,000 ft.
STATUS:	In production
PAYLOAD:	3,000 lbs.
REMARKS:	Tactical, aerodynamic surface-to-surface, Nuclear warhead

The latest version MATADOR, TM-61B, is longer and has shorter wings than models A and C.

Below, Northrop's SNARK takes off from Patrick AFB at night. Two solid propellant boosters accelerate the missile from its zero-length launching rail. Missile cruises (above) at Mach 0.94. Range is 5000 miles. Warhead is delivered at supersonic speed.

U.S. Air Force's

SNARK

The Northrop *Snark* is the first intercontinental missile to go into production for the Air Force. It is expected that units of the Strategic Air Command will commence training with the weapon in the last quarter of 1958. It is a joint development of Northrop and the Air Research and Development Command. The SM-62 has demonstrated its long range and accuracy in numerous successful flights over the sea test lanes reaching southward across the Atlantic from Patrick Air Force Base.

It is a high altitude, swept-wing, single-engine, jet-propelled intercontinental guided missile equipped to guide the missile over extended distances for long-range delivery of a nuclear warhead. It has slim fuselage lines, with high-aspect ratio wings mounted near top and slightly forward of center of fuselage. Tail consists only of a vertical stabilizer. Engine air intake is located below underside of fuselage and aft of wing junction. The thin wings have a "sawtooth" leading edge. Elevons—combination ailerons and elevators—on the trailing edge of the wing eliminate the need for a horizontal tail.

Snark is powered during cruise flight by a Pratt & Whitney J-57 turbojet engine. Aerojet-General Corp., Azusa, Calif., supplies the zero-length solid-propellant boosters which hurl it

The Aerojet solid propellant boosters for the SNARK each yields 33,000 pounds of thrust. Zero-length launcher rail measures 29 feet.

into the air without a take-off run.

Snark is designed for a range of more than 5,000 miles; at least one flight of about 2,000 miles has been recorded. It utilizes a combination inertial and celestial guidance system. The weapon is subsonic, reportedly cruising at a speed of about Mach .9. Its altitude capability is probably better than 50,000 feet during the latter portion of its mission. It carries out its mission despite night or inclement weather. It can fly above turbulent weather and over long distances.

The *Snark* can be "zero" launched from a stationary or mobile launcher in a relatively small area. The missile and launcher are extremely mobile and can be flown to any point in the world within a few hours. The missile and its ground support equipment are normally transported by C-124 Globemaster aircraft and can be set up in launch position within a short time after its arrival at a given destination.

The mobile launcher, also developed by Northrop to Air Force strategic considerations, is a basic element of advanced ground support equipment which enables the *Snark* to aim its nuclear punch from a hidden site in any type of terrain—mountains, desert, or Arctic wastelands.

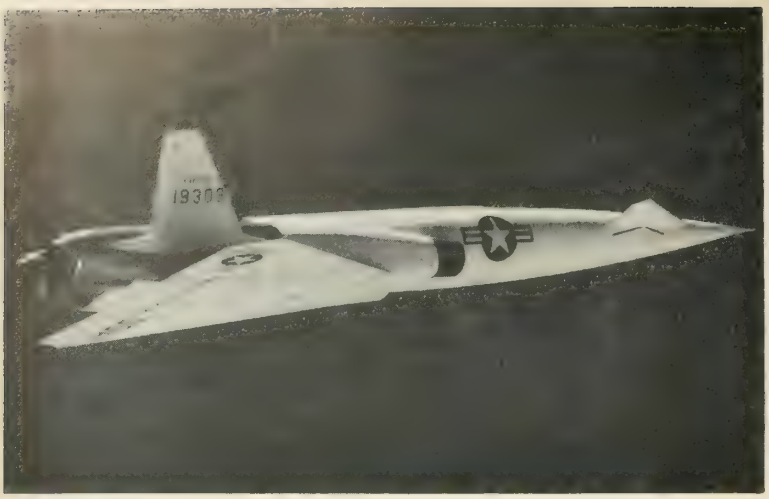
Designated the SM-62, the weapon is viewed by top Defense Department officials as a competitor to the North American *Navaho*. Former Deputy Defense Secretary Reuben Robertson, Jr., told the House Defense Appropriations Committee earlier in the year: "We view the *Snark* and *Navaho's* approach in the air breathing intercontinental group quite similar to the *Thor* and *Jupiter* competitive situation. One of them is going to win that race and one of them should be put into inventory."

Asked why the Defense Department continued its support of *Snark* in the face of opposition from Eger V. Murphree, former special assistant to Defense Secretary Charles Wilson for guided missiles, and other high military officials, Robertson replied:

"We felt that this is a weapon in which we had such a large investment that we should go ahead and get it in the inventory. While it has its disadvantages in being subsonic, it will probably have quite an accurate guidance system as now visualized, a very good CEP (circular error probability)."

The advantage of the air breathing missile is that, compared to its ballistic competitor, it's relatively slow in its terminal dive on target and is thus more readily susceptible to detection and interception. This advantage accrues to the ballistic missile only so long as an effective anti-ICBM missile has not been developed. But once such a counter-system is operative, the ICBM is then without further recourse. In the ballistic phase of its trajectory it cannot take evasive action and furthermore, it cannot—because of the conditions of reentry—employ countermeasures, electronic or otherwise.

• • •



It's a big bird with plenty of room, auxiliary power supplies and full control over its course. SNARK can take evasive action, on-board countermeasures can be easily altered.

SPECIFIC DATA:

MANUFACTURER: Northrop Aircraft Inc.
MISSION: surface-to-surface aerodynamic cruise
RANGE: 5000 mi.
VELOCITY: Mach 0.94
WEIGHT: 35,000-38,000 lbs.
LENGTH: 74 ft.
HEIGHT: 15 ft.
DIAMETER: 4.5 ft.
SPAN: 42 ft.
GUIDANCE: Northrop MK I celestial and inertial (wt. 1,000 lbs.)
POWERPLANT: P&W J57 (11,000 lbs.) has also used Westinghouse J40 and Allison J71
ALTITUDE: 60-75,000 ft.
LAUNCHER: (2) Aerojet SPR Boosters (33,000 lbs. ea.) and zero-length rail (29 ft.)
STATUS: pre-production and redesign
REMARKS: intercontinental aerodynamic cruise missile

Operational tests using SNARK-type missiles against combined defenses show that this kind of missile is difficult to intercept. SAC is expected to employ SNARKs in 1958.

U.S. Air Force's

NAVAHO

Most ambitious of all air-breathing surface-to-surface missiles presently under development is the North American XSM-64 *Navaho*, an intercontinental weapon.

The Air Force-financed missile is undoubtedly the largest of all air-breathers. Although no photographs have been released, the weapon is said to be aerodynamically similar to the X-10 turbojet-powered test vehicle. Flight tests with the X-10 were completed early this year.

Navaho employs two large Curtiss-Wright ramjet motors for cruise power, plus a liquid-propellant rocket booster system for take-off and acceleration to the high Mach number necessary to permit the ramjets to ignite. *Navaho* models now under test employ a set of three North American rocket engines of 120,000 pounds thrust each for initial boost; the projected SM-64 production *Navaho* is scheduled to use a single North American motor of more than 400,000 pounds thrust. Latter is in advanced development.

As in the case of most missile developments, preliminary firings of the *Navaho* have been plagued with failures for trivial reasons. First XSM-64 aborted at 9,000 feet when a rate control gyro failed.

On the second firing attempt at Patrick, the big missile tore away part of its launching apparatus on take-off, causing the booster to lose power and the vehicle to fall in the sea. The third trial in April was a complete failure because the rocket boosters quit firing after two seconds in response to a wild signal from within the missile.

One of the interesting features of the XSM-64 is the fact that it incorporates retractable landing gear. A dead-stick landing procedure was worked out with the X-10, and it is hoped that some of the vehicles can be recovered for re-use.

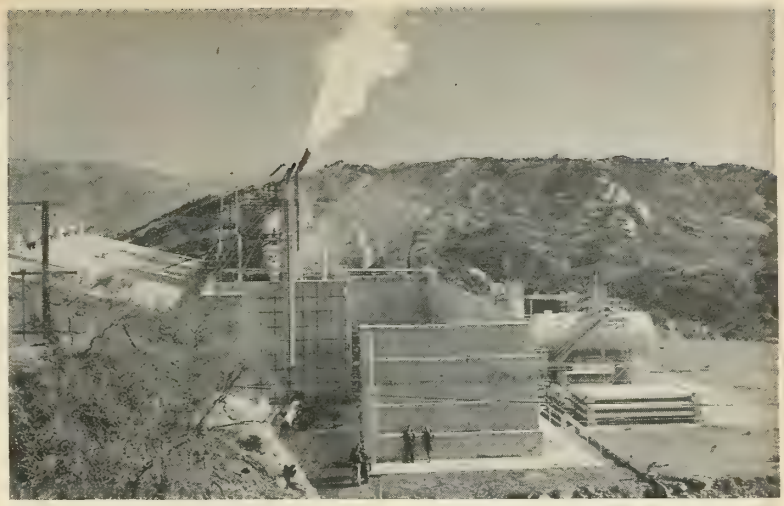
The Defense Department last year struck out the Air Force's request for funds to support the *Navaho* in fiscal 1958, forcing the airmen to "reorient" the program to make fiscal 1957 funds last as long as possible. A decision on whether to go ahead with the *Navaho* will probably come in the fall.

The outlook now does not appear favorable for the weapon. Funds are expected to remain extremely tight, and top Defense officials have made it known they believe one air-breathing intercontinental missile is enough for the Air Force.

But many things might happen to change top-level Defense thinking, and test work on the *Navaho* will continue. North American believes its warhead-accuracy potential is much greater than that attainable with the intercontinental ballistic weapons, and that *Navaho* therefore has a specific place in the nation's future arsenal.

Whatever the *Navaho's* ultimate fate, its development has contributed more to advance the state of the missile art in the U.S. than any other single factor. It has introduced North American to many brand new fields of activity, including development of most of the engines which will be used in future ballistic missiles.

• • •



X-10, North American Aviation's unmanned test vehicle for AF's SM-64 NAVAHO intercontinental strategic aerodynamic cruise missile has concluded its flight test program. Launched by rockets and powered by turbojets, X-10 has provided much valuable research and development data for other missile programs. NAVAHO will use modern ramjet sustainers.

SPECIFIC DATA:
MANUFACTURER: No. American Av'n., Inc.
RANGE: more than 5,000 mi.
WEIGHT: (estimated) 200,000-300,000 lbs.
VELOCITY: Mach 3-3.5
ALTITUDE: 70,000-80,000 ft.
PROPULSION:
Booster; Three NAA liquid-propellant rocket engines, total thrust of 360,000 lbs.
Sustainer; Two Curtiss-Wright ramjet engines
STATUS: development
MISSION: surface-to-surface aerodynamic cruise

U.S. Air Force's

THOR

THOR's 135,000-pound thrust power plant is made by Rocketdyne Division of North American Aviation, Inc. Here, rocket engine gas generator flares at Rocketdyne test facility.

The WS-315 *Thor* is the Air Force's entry in the Intermediate Range Ballistic Missile race. Its main competitor is the Army's *Jupiter* IRBM, although the Navy is also developing an IRBM of its own, the *Polaris* Fleet Ballistic Missile.

The *Thor* is a single-stage weapon powered by a North American liquid rocket engine with a thrust of 120,000 to 140,000 pounds. Its range is 1500 miles. Its airframe is manufactured by Douglas Aircraft Co. Inc., while A.C. Spark Plug Div. of General Motors Corp. is developing the guidance. The nose cone undoubtedly features the blunt shape proposed by the National Advisory Committee for Aeronautics in 1953.

First test firings of new missiles are almost invariably fraught with surprises and failures, and the *Thor* has proven to be no exception. On its first launching trial, foreign matter contaminated the oxygen system and the engine failed to receive sufficient LOX to maintain combustion. Thrust deteriorated when the vehicle was a couple of feet in the air and it sagged back to the launching stand, broke in two and exploded.

On the second firing attempt, the USAF entry in the IRBM race appeared to wander off course and was detonated after a flight of 38 seconds. Later it was said that the range safety officer's radar monitoring system was out of kilter and that the missile was actually on course. But the third launching effort was even more frustrating; four minutes before launching, an electrical short circuit started a fire and the missile burned up without ever leaving the ground.

Despite these unhappy experiences, the Air Force is confident it will be able to prove out the *Thor* and that the weapon—or most of it—will ultimately be selected for quantity production for operational use with the Strategic Air Command.

Early this year, the Air Force announced it had awarded a $67,500,000 contract to Douglas for fabrication and testing of *Thor* airframes. The period covered by the contract was not disclosed, but the Air Force did say that none of the funds covered development of engines, guidance or other components.

The Air Force has frequently pointed out that the *Thor* development program is a considerable bargain because many of the components of the rocket missile are being developed for its big brothers, the *Atlas* and *Titan* Intercontinental Ballistic Missiles.

The Air Force was given complete operational control over all surface-to-surface land-based missiles with a range of more than 200 miles by the terms of Defense Secretary Charles Wilson's memorandum on roles and missions last November. Principal effect of the memorandum was to turn the Army's *Jupiter* over to the Air Force, for further financing and operational use.

SPECIFIC DATA:

MANUFACTURER: Douglas Aircraft Co.
Mission: surface-to-surface IRBM
RANGE: 1500 mi.
VELOCITY: Mach 10
GUIDANCE: radio-inertial by AC Spark with assistance from Bell Telephone Labs
POWERPLANT: (1) NAA LPR (135,000 lbs.)
STATUS: prototype firings ($67.5m for continued development)
REMARKS: Intermediate range ballistic missile; nose cone—GE; warhead—Sandia Corp.

THOR engine under test? The canyons rock with the thunder of captive power. This Rocketdyne test stand is high in the Santa Susana Mountains, 35 miles from Los Angeles.

First official photos of Atlas test base. Atlas missile systems are checked out in this test tower in Sycamore Canyon, a secluded military reservation N.E. of San Diego.

U.S. Air Force's ATLAS

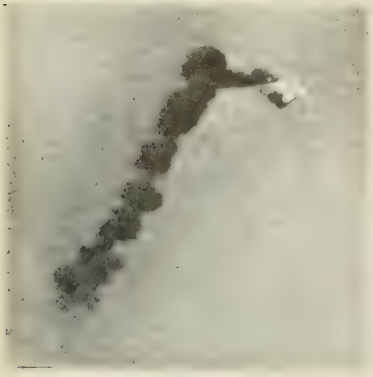
The WS-107 *Atlas* is the first of the most ambitious line of missiles yet attempted—the Inter-Continental Ballistic Missile, ICBM. It is officially described as being in pilot production at Convair's Astronautics Division at San Diego, Calif. The missile is now in the test flight stage, being fired from Patrick AFB, Fla. Components and systems test other than engine run-up is conducted at Convair's special facility on the ocean side of Point Loma, San Diego Bay, Calif.

Convair Div. of General Dynamics Corp. initiated work on the *Atlas* project as far back as 1947. With Air Force funds, it developed and fired several models of the MX-774 liquid-propelled missile to determine the feasibility of a gimballed motor. During the lean days of the late 1940's, it carried the project with its own funds.

It was not until about 1953 that the feasibility of an ICBM became clear. The U.S. succeeded in detonating a true hydrogen bomb (in contrast to a hydrogen *device*), demonstrating that a warhead of titanic power could be wrapped up in the relatively small confines of an ICBM's nose section. This at once had the effect of sharply diminishing the ICBM's size as well as broadening its permissible circular error probability to limits deemed attainable with guidance equipment within the state of the art.

A second "technological breakthrough" was the discovery by the National Advisory Committee for Aeronautics that a blunt nose cone could reject 90% or more of the re-entry heat to the atmosphere by setting up a strong shock wave. This substantially alleviated cooling problems and cleared the way for the Air Force's present $1 billion a year ballistic missile effort.

No photos have yet been officially released on the *Atlas*, but several bits of information have been gleaned during the past several months regarding its probable configuration. It is understood the weapon utilizes three North American liquid-propellant engines—two boosters of about 120,000 pounds thrust and a sustainer motor of 140,000 pounds. The boosters and presumably their turbopumps and tankage are jettisonable when they burn out.

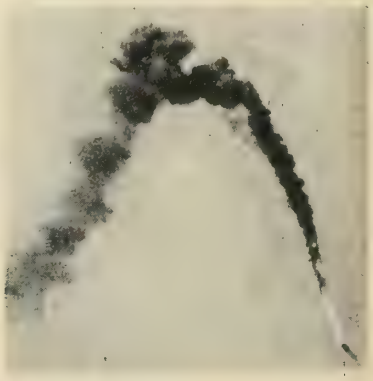


Also, the wide publicity given the precise date and time of the highly secret first firing of the *Atlas* configuration resulted in several hundred people being on hand about the land perimeter of Cape Canaveral, many of them photographers with the best in long lense equipment.

On this first firing, the 5,000-mile missile went between 5,000 and 10,000 feet before it was intentionally detonated by the range safety officer. From the appearance of the missile in flight, this apparently is what happened: The twin boosters fired properly until the missile reached between 5,000 and 8,000 feet. Then one of the liquid rocket engines apparently suffered a failure in its LOX supply. The flame went from a crisp clean yellow to a dirty orange. Black smoke belched forth. Loss of power in one of the paired engines caused a violent yaw. The missile made at least two efforts to correct for this before it was detonated.

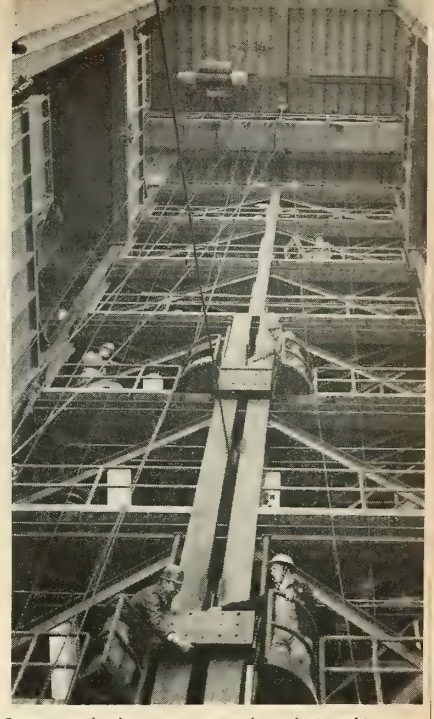
Quite a number of pictures were taken of the missile during this period and have been published. Study of them reveals that surrounding the engine nozzles is a flare to provide directional stability. The missile has no fins as such. The pictures also reveal that the missile was not fired with its final nose cone, but utilized a fairly conventional low-drag-to-weight ratio shape instead.

The actual nose cone, rather than being sharply tapered and pointed as shown, will be very blunt with a heavy metal base probably coated with laminated plastic. It is scheduled to be attached to later test models.



Length of the *Atlas* is something

Prototype of the Atlas ICBM was fired from Patrick AFB at Cape Caneveral last month.



A mass of flames and spiraling at 10,000 feet the Atlas ICBM leaves a trail of black smoke.

The Patrick AFB range safety officer exploded the missile because one engine failed.

Sycamore is one of three facilities where Convair, Division of General Dynamics Corp. is testing the Atlas missile. Component testing is conducted on Point Loma in San Diego.

Systems checkouts are conducted in this huge tower at Convair's San Diego facility.

under 100 feet, and take-off weight is probably more than 200,000 pounds. Its maximum range is 5,500 miles and its apogee is about 800 miles. It will attain speeds of approximately 15,000 mph upon its re-entry into the atmosphere. To test re-entry problems with full-scale nose cones, the Air Force is using the Lockheed three-stage X-17, powered by Thiokol *Sergeant* and *Recruit* solid-propellant motors. Speeds of about 9,000 miles per hour have been achieved with this device, equal to about one-quarter of the re-entry energy of an ICBM.

Just when the *Atlas* is expected to be ready for operational use has never been disclosed publicly, but it is certain that it will be sometime after 1960 and probably later than the operational date now expected for the *Thor-Jupiter* IRBM.

Probably the most crucial problem with the *Atlas* at the present time is guidance accuracy. Most officials expect this will prove to be the toughest headache of all, and many companies have been brought into this phase of the program to work on alternate solutions. (See *Titan,* p. 162) Hinging on the answer to this question is the timetable for reduction of the Air Force's fleet of manned bombers.

Commented one Air Force wag: 'I foresee two broad periods in the ICBM program. In the first period, we can probably be sure of missing Western Europe and hitting Russia. In the second period, we can guarantee strikes within reasonable distances of specific targets. The trouble is, I can't tell you how long that first period will last, and so, I can't say when we will be able to de-emphasize manned bombers."

• • •

SPECIFIC DATA:

MANUFACTURER: (San Diego)	Convair Astronautics
MISSION:	surface-to-surface ICBM
RANGE:	5500 mi.
SPEED:	Mach 15
WEIGHT:	over 90 tons, take-off
LENGTH:	70 ft.
DIAMETER:	body 8 ft. 6 in.; flare, 12 ft.
GUIDANCE:	original AC Spark radio-inertial system cancelled; now inertial system by Arma ($1.1 mi. contract) assisted by the Bell Telephone Labs (ground control)
POWERPLANT:	(1) NAA LPR sustainer (100,000 lbs.) (2) NAA LPR boosters (135,000 lbs. ea.)
ALTITUDE:	800 mi. peak trajectory
STATUS:	Flight Test
REMARKS:	intercontinental ballistic missile auxiliary power-AMF; thermonuclear warhead-Sandia Corp.; nose cone and re-entry body-GE.

Special trailer was built to transport the Atlas ICBM missile from San Diego to Patrick Air Force Base. Second Atlas firing is understood to be scheduled for next month.

U.S. Air Force's TITAN

The *Titan* (WS-107) Intercontinental Ballistic Missile is an alternate approach to the ICBM problem. The missile's airframe is under development by The Martin Co. in a new $20 million facility near Denver, Colo.

Aerojet-General Corp. is developing *Titan's* propulsion system. According to a recent speech by Dan Kimball, president of Aerojet, the company is working on a propulsion system for a long-range ballistic missile which includes a first-stage rocket engine of 300,000 pounds thrust at sea level, and a seven-stage engine of 60,000 pounds thrust at sea level. These engines are undoubtedly intended for *Titan*.

In configuration, the *Titan* would appear to be a tandem, two-stage missile like the Army's *Nike* or the Navy's *Terrier*. First stage would carry the weapon up to altitude before the second stage motor is ignited, as distinguished from the *Atlas* system in which all three motors are fired simultaneously on the ground.

Development of the *Titan* was ordered late in 1955 when it was decided to put the USAF ICBM program on something approaching a "crash" basis. The Martin weapon does not duplicate the Convair *Atlas*, although many of its components are common to both systems. In discussing the decision to go ahead with a second ICBM program, former Air Force Secretary Donald Quarles said last year:

"This plan enables us to conduct simultaneous development of two operational missiles, representing different technical approaches, at an estimated increase of only 10% of the cost of developing a single configuration. The decision to pursue two different approaches was prompted by the desire to assure earliest possible success in our ICBM effort."

Actually, the airframes and propulsion systems of the *Atlas* and the *Titan* appear to be so distinctly different that it is unlikely that these can be regarded as interchangeable. This may not be true of the nose cones under development for the two missiles, and it certainly is not true for the various guidance systems. Both the Special Projects Department of General Electric Co., Philadelphia, and the Research Div. of Avco Manufacturing Corp., Everett, Mass., are working on nose cones for the two missiles.

A total of seven contractors are working on guidance for the USAF ballistic missile program, but the Air Force still has not linked individual contractors to individual ballistic projects. They include: Heavy Military Electronics Div. of GE, Syracuse, N.Y.; American Bosch Arma Corp., Garden City, N.Y.; A.C. Spark Plug Div. of General Motors Corp., Milwaukee; Burroughs Corp., Paoli, Pa.; Univac Div. of Sperry-Rand Corp., St. Paul, Minn., and the Instrumentation Laboratory of the Massachusetts Institute of Technology.

Specifically these appear to be the main contractors for Martin's *Titan*. An initial USAF development contract totaling $358 million has reshaped the geographic organization of its prime airframe contractor—The Martin Co. The *Titan* program, centered by Martin in a new $10-million facility in Denver, is already outgrowing the bounds of initial planning.

As a result, a $2-million plant expansion is already in the mill. Present employment of 2,500 is expected to reach 5,000 next year.

Titan propulsion is assigned to Aerojet-General at Azusa, Calif. Prime contractor for nose cone development is Avco Manufacturing Corp. at Lawrence, Mass. with Lockheed Aircraft Corp.'s Missile Systems Division lending research support to both the *Atlas* and *Titan* nose cone R&D effort via its X-17 research project.

In *Titan* guidance, American Bosch Arma Corp., of Garden City, N.Y. is spearheading inertial guidance development and Bell Telephone Laboratories/Western Electric Co. at Whippany, N.J. is tackling radio guidance.

In addition to these prime development assignments, American Machine & Foundry Co.'s Turbo Division is developing auxiliary power units for unnamed missiles.

Two missile firms, Associated Products Corp. of Pomona, Calif. and Hallamore is also subcontractor to conbair in the *Atlas* project.

Baldwin - Lima - Hamilton Corp. holds subcontracts from Martin for *Titan* test stands and, in turn, has contracted with Beckman Instruments, Inc. to supply specialized computers. Douglas has also ordered Beckman data processing equipment to speed *Thor* research.

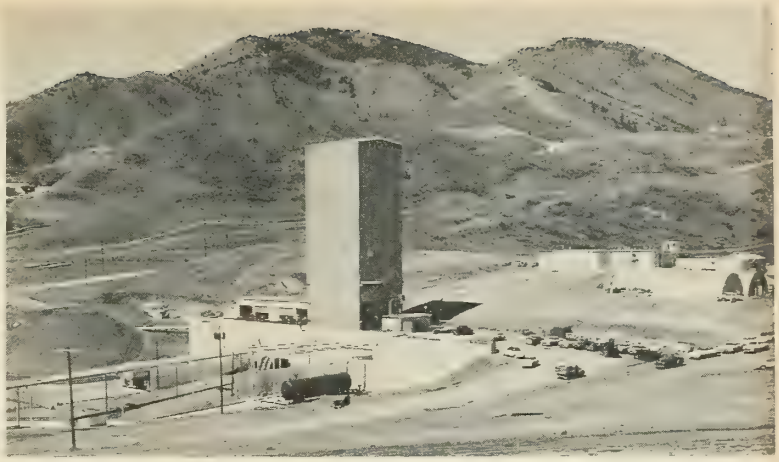
Burroughs Corp. holds contracts for data processing equipment in the ground control equipment for the IRBM/ICBM program. Fruehauf Trailer Co., Los Angeles plant, is building special *Thor* truck-trailers under a $15-million subcontract from Douglas.

But these are only a few of the 200 subcontractors active to date in the ICBM and IRBM in the programs.

Four static test stands are being completed at Martin's Titan facility near Denver, Colo.

The roster of the unnamed, obviously even more impressive by its numbers alone, remains to unfold.

Defense Secretary Charles Wilson recently voiced a somewhat cryptic comment about the ICBM program. Discussing the two weapons, he remarked to a Senate Committee: "The one we think is best" is probably "farther behind." Developmentwise, the *Titan* is behind the *Atlas,* so Wilson may have been expressing a preference for the former weapon system.



The initial USAF *Titan* development contract, totaling $358 million, has reshaped the geographic organization of the Martin Co. The *Titan* program, centered in the new $10-million facility here, is already in its manufacturing stage.

As a result, a $2-million plant expansion is in the mill. Present employment of 2,500 is expected to reach 5,000 next year. Company officials say building of a landing strip is planned to expedite delivery of parts and for transporting military and civilian people to the site.

The *Titan* program now is broken down into eight departmentalized functions which perform specialized responsibilities in successfully completing the project. Several of these are well underway.

The propulsion section, which has the responsibility for the engine installation, its propellant feed system and its satisfactory marriage to the airframe, is working closely with Aerojet, planning first engine tests at the Denver site.

The airframe section has the responsibility for the design of the structure, the orientation of the various systems within the structure and the general configuration of the missile. This work is in the mill.

Martin's Titan intercontinental ballistic missile effort is in a far more advanced stage than was expected a year ago. Some design conceptions from the Atlas have been incorporated.

The guidance and control section has the responsibility for the analysis, design, development and installation of all of the control equipment which will help the vehicle maintain a stable flight attitude at all times and the integration for guidance within the entire system. Little is known of guidance progress, but it must be assumed that it is as advanced as the *Atlas* guidance.

The ground support and equipment section, which has the responsibility of supplying all the necessary equipment required to launch the vehicle, is well ahead in its overall planning. In all, the *Titan* program is well advanced, and, needless to say, Air Force officials are pleased with the progress.

SPECIFIC DATA:

MANUFACTURER: Martin Co.
MISSION: surface-to-surface ICBM
RANGE: 5,500 mi.
SPEED: Mach 15
WEIGHT: 200,000 lbs. plus
HEIGHT: (est) 100 ft. plus
GUIDANCE. ARMA inertial
POWERPLANT: 1st stage-Aerojet LPR (300,000 lbs.)
2nd stage—Reaction Motors LPR (60,000 lbs.)
GROUND CONTROL: radio ground guidance by Bell Telephone Labs
PROPULSION:
Booster: 300,000 lbs. thrust Aerojet LP motor
Sustainer: 60,000 lbs. thrust Aerojet LP motor
STATUS: component development; $358m in January for continued development
REMARKS:
ICBM, Nose cone-AVCO
warhead-Sandia Corp.

Martin expects to employ 5,000 people at its Denver facility by the end of the year. Most construction work has been completed.

Aerojet's giant-size engines for Titan have been successfully developed and will be at the Denver site for test shortly.

MISCELLANEOUS MISSILES

DING-DONG MB-1 (Bird Dog High-Card)

The *Ding-Dong* MB-1 was the first air-to-air missile to have an atomic warhead. Developed for the Air Force by Douglas Aircraft Co. it was reportedly flight tested with an atomic nose during the May 1957 AEC atomic firings. Liquid and solid propellant versions are under development although the liquid propellant model was the first conceived. Atomic warheads for air-to-air missiles were tested in the spring of 1955 to provide basic information on the missile requirements. Design for the *Ding-Dong* was initiated in 1956.

SPECIFIC DATA:
MANUFACTURER: Douglas
MISSION: air-to-air
GUIDANCE: Hughes
POWERPLANT: NAA LPR (latest version has SPR)
STATUS: reactivation of an earlier Douglas project; in late development or early production
REMARKS: air-to-air interceptor missile, atomic warhead; TINGALING is ballistic spotting version.

GREEN QUAIL

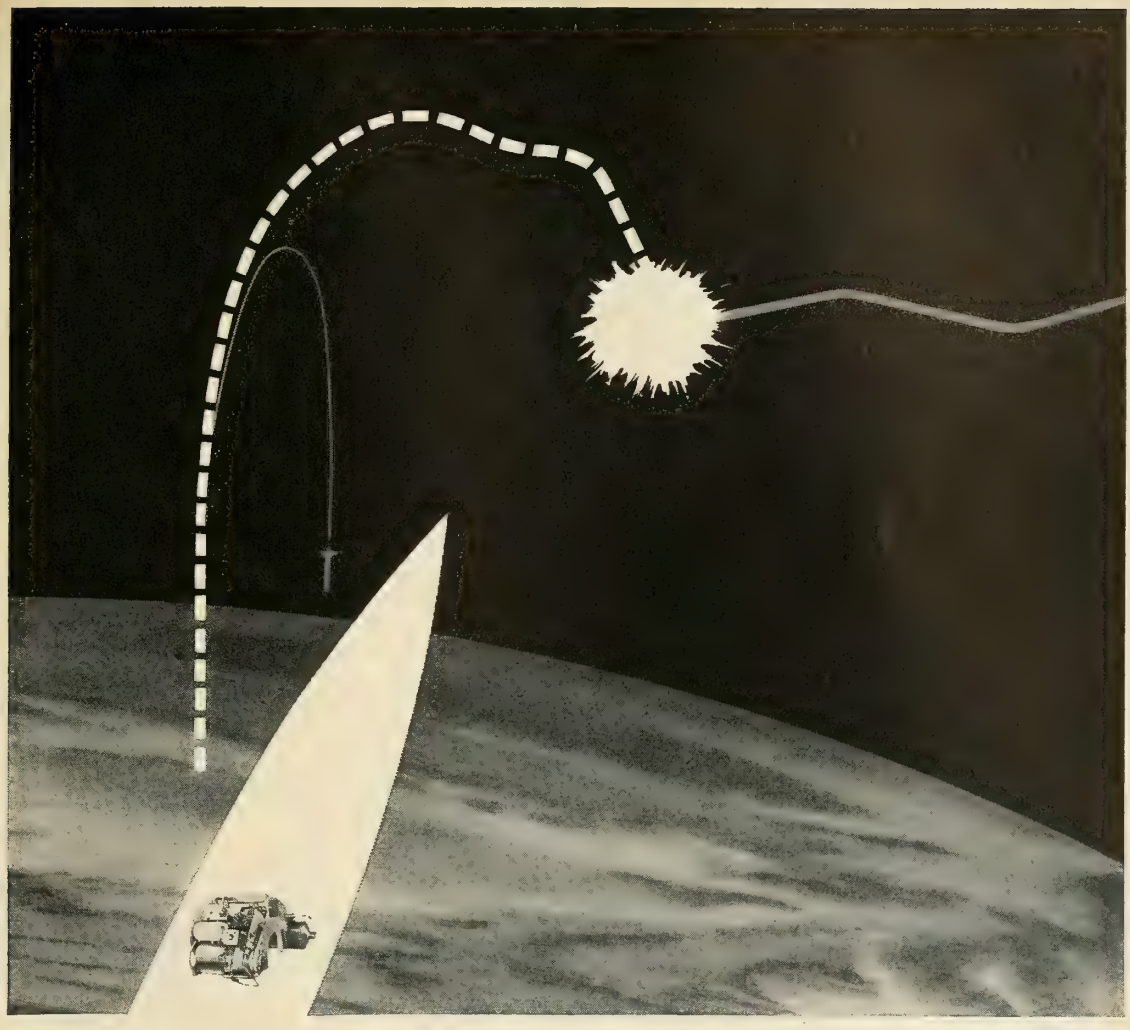
Green Quail is an air-to-surface diversion missile understood to be a member of the *Corvus* family. Missile is believed in late stage of development with first flights expected in early 1958.

SPECIFIC DATA:
MANUFACTURER: McDonnell Aircraft
MISSION: air-to-surface diversionary
GUIDANCE: Sommers Gyroscope
STATUS: late development

DUCK

An air-to-air missile in the research and development stage designed as armament for our long-range and supersonic bombers. The role of this missile as a BDM weapon has not been confirmed at this time. Fairchild is reported as the prime contractor for this Air Force missile.

GOOSE



An air-to-air bird in the development and production stage manufactured by Fairchild as a diversionary drone. Launched from a bomber, the *Goose* was designed to decoy intercepting planes or missiles from bomber strike force, i.e., B-52 or B-58 atomic carriers. This turbo-jet aerodynamic cruise missile will probably be operated similarly to the *Rascal* air-to-surface missile. The B-58 *Hustler* has been mentioned as the carrier for the *Goose* and *Duck*.

SPECIFIC DATA:
MANUFACTURER: Fairchild Aircraft
MISSION: air-to-air diversionary
LENGTH: 20 ft. (est)
VELOCITY: Mach 1.25
SPAN: 13 ft. (est)
GUIDANCE: Fairchild radio command
POWERPLANT: Fairchild J-83 or GE J-85
ALTITUDE: 100,000 ft.
LAUNCHER: mother plane
FLIGHT CONTROL: Kollsman
STATUS: production

WS-126A WS-132A

The WS-126A is reported to be under the systems engineering management of Cornell Aeronautical Labs, DE Johnson City. Bell Telephone, Hughes and Raytheon have been engaged in the design and development of a bomber defense missile (WS-126A) for the B-52. Recent indications, however, are that the project has been de-emphasized although it remains a critical AF requirement. It is anticipated that the project will be kept alive.

The WS-132A was to have been the bomber defense missile for the WS-110A. Two development teams (GE/-McDonnell and Republic/Westinghouse) were working on this missile until work was suspended by an AF stop order issued in November 1956. Arma is believed to be still working on a competitive system.

For the "killing" demands of accessory power...

AMF has experience you can use

• No part of a missile is more important than the power supply that directs it to the "kill". And AMF has produced more gas turbine power units for guided missiles than any other source. • Typical AMF systems produce up to 50 hp.—with modifications, up to 200 hp.—at durations from 20 seconds to many hours. They are completely independent of the main power plant, insensitive to missile attitude or altitude, and to environment, acceleration, shock, or vibration. • Units offer multiple start-stop flexibility, precise frequency and voltage control, and can be packaged to fit practically any space arrangement, with little size and low weight. • See for yourself why, in accessory missile power as in a variety of other highly specialized fields, AMF has experience you can use.

Electro-Snap Switches Can Be Adapted to Almost Any Job — Quickly, Easily, Economically

Switching Problem?

Just choose the Electro-Snap Basic Switch that meets your electrical requirements, add the proper actuator — and presto! — you have a tailor-made precision switch that exactly fits your application. Electro-Snap makes a wide variety of stock actuators to fit almost any requirement. And our engineering department is at your service if a standard combination "won't fill the bill."

For prompt action on your switching problems, send us a brief description and rough sketch of the switch you need.

SUB-MINIATURE SWITCHES TYPE E-4

S.P.D.T., 1 circuit; 5 amps, 125/250 v. AC Operating force 150 grams max. Exceptionally vibration-resistant. Special model E4-7 is stabilized for — 65° to + 350° F. operation.

Space Medicine

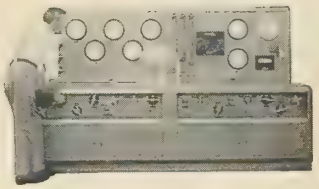
by Hubertus Strughold, MD., PhD.

An important research area in space medicine is the study of the toxicity of rocket propellants—fuels as well as oxidizers. This is a kind of preventive medicine. Basically, the injuries may be caused by chemical reactions with body tissue or by thermal burns, such as those caused by liquified propellants at very low temperatures.

The areas of attack are usually the skin, the eyes, the respiratory tract, and the digestive tract. Protective measures must be taken—special clothing, face shields, etc. The problem of propellant toxicity concerns both crew and ground personnel, and pertinent instructions are important for both.

Ozone is used as an oxidizer in rocket propulsion and is also found in higher concentrations in the atmosphere between 60,000 and 140,000 feet (the ozonosphere). Recently ozone has attracted special medical interest. Dr. H. G. Clamann of the School of Aviation Medicine at Randolph AFB, Tex., in cooperation with Armour Research of Chicago, has carried out experiments in an ozone chamber to determine human tolerance to the gas.

The high altitude balloon flight of Capt. J. W. Kittinger on 3 June was a test in the balloon program of Maj. David G. Simons of the Aeromedical Field Laboratory at Holloman AFB, N. M. From the standpoint of human physiology the altitude reached by Kittinger—96,000 feet—can be considered equivalent to the vacuum of space.



The true nature of the so-called boiling of body fluids above 63,000 feet has been discussed in a paper by Capt. Julian E. Ward, Jr., (J. Av. Med., Vol. 27, pp. 429-439, Oct. 1956). This low-pressure, low-temperature vaporization is a physical process, and does not include chemical reactions in the tissues as in the boiling of food during which protein coagulates. For this reason, the author suggests that a new term "ebullism" (derived from *ebullare:* to form bubbles) should be applied to the phenomenon. The term "boiling" is misleading and should be discouraged, especially in the press. The boiling of body fluids at altitude is actually an unhindered, profuse vaporization.

At the annual meeting of the Aeromedical Association in Denver May 6 to 8, Dr. Alberto Hurtado gave the Louis H. Bauer Lecture on "Natural Acclimatization to High Altitudes." Dr. Hurtado is Research Director of the Institute of Andean Biology at Lima, Peru. It is the only place where acclimatization studies are continuously carried out at altitudes as high as 15,000 feet. The subjects are natives and visiting researchers.

At the same meeting, Prof. R. Margaria, Director of the Physiological Institute at the University of Milan, Italy, reported on experiments in which he immersed fish in water, placed them on a centrifuge, and subjected them to 1500 g for periods up to 10 minutes. They survived for more than twenty-four hours after this extremely high gravitational stress. Frogs survived after exposure on the centrifuge to several hundred g while they were immersed in water.

On July 19 a symposium on Astronautics, organized jointly by the Royal Aeronautical Society, the British Interplanetary Society and the College of Aeronautics, will be held at Cranfield, England. Papers of interest in the field of Space Medicine will be given by Lt. Col. James P. Henry, Chief of the Biosciences Division, ARDC titled "Psychophysiological Hazards of Satellite Flight," and by H. G. Clamann, School of Aviation Medicine, on "Medical Problems in Bio-astronautics."

Missile Miscellany

Six months ago this page started out with a stated main purpose to make people think. Perhaps the clause should have been added: ". . . even if it has to make them mad to do it." Sometimes it's the only way.

With this semiversary note, this page hears: That AF has made at least two efforts to provide sufficient financial incentive to induce private companies to buy away Wernher von Braun Army missile team; that AF recently attempted to cut off Jupiter without a cent of fiscal 1958 R&D money but was foiled by Defense Secretary Wilson; also that AF, rather than famed missile-maker Douglas Aircraft, should take blame for Thor fiasco—for scheduling the impossible and then saying: "Hurry!" With all this, plus interesting timing of Air Force Magazine's "Great Missile Hoax" vis-a-vis Army Jupiter's 1500 mile shot vis-a-vis AF Atlas' 8000 foot misfire, seems like there might be room for another magazine, called Missile Politics, to tell John Q where his missile tax money is really going.

Now to a Russian Admiral admiring Bomarc exhibit on Armed Forces Day who asked: "Can this be used for anti-submarine work?" On the same missile, a query tossed out the other evening: "Why doesn't it have a competitor?" And a quip circulating Washington: "It's going to take a fourth stage engine just to get Vanguard through the red tape!"

But speaking of serious projects, AF's TV-carrying Big Brother satellite may be running ahead of schedule, spurred on by anti-missile missile need to know instant enemy ICBM is fired. Tip-off may be delivery to AF in nine months of a one kilowatt hydrogen-oxygen fuel cell that needs no heat sink; can operate at temperatures from −175 to 350°C at zero gravity with 5-lb./kwh or less weight-to-power ratio and at least 30-day operating life. Proving you never know where missile knowhow's going to pop up next, spheres of Haveg high-temperature material fitted with Diversey-machined molybdenum will measure for the first time ever the molten cores of the world's eleven major active volcanoes at rate of one a year. National Geographic Society's to pay and plans first shot this year in Peru.

Totally unclassified discussion the other morning of problems of getting anti-missile missile high enough soon enough brought this conclusion: Must be solid propellant for instant readiness—these suggestions: by-pass duct a solid propellant motor to add air mass to rocket efflux; core intermediate stage into solid fuel ramjet; afterburn in secondary nozzle behind conventional solid propellant motor (all these designed to put atmosphere to work) —and this forecast: Startling AMM developments within months.

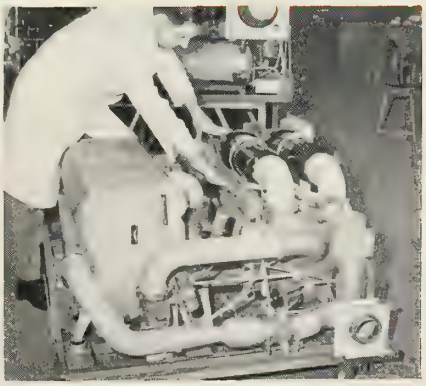
Why doesn't American Rocket Society set up a missile launching base where tomorrow's space-flight engineers, today's amateur missileers can safely static test and fire their hardware? This page bets manpower-hungry missile industry would foot bill if ARS administered. Insurance is no excuse. Lloyd's in London will bet for or against anything.

Now jumping from pad-to-pad—Navy's "second Admiral Rickover" (for missiles, that is), Robert C. Truax, is reportedly on his way back to Washington to head up Polaris Fleet Ballistic Missile program. About time . . . Shades of Swedish sub-seeking seals, U.S. Navy at end of World War II seriously contemplated use of hungry homing pigeons for guiding missiles . . . Credit to a radio disc jockey who quipped: "Nuclear warheads now come in three sizes: small, large and 'where did everybody go?' " . . . This unfortunately apt goal in electronics gear design: To make it idiot-proof . . . Employment at Redstone Arsenal and ABMA's Guided Missile School is highest ever at over 14,400 . . . And a serious report that man may place his finger on the moon by Christmas . . .

IN PRODUCTION AT STRATOS

TYPE MB-1 AIR CONDITIONER

tratos' experience with airborne air conditioning systems has been pplied to a new, lightweight air conditioner designed for use with gas urbine compressors such as the MA-1A and MA-2 types. Meeting ype MB-1 requirements, the unit is Stratos' Model GEA120-1.



Composed of aircraft quality components, the system is packaged s a compact unit measuring only 48″ x 50″ x 30″. The controls—onnected to the package solely by an electrical cable—can be remotely ocated and, where desired, taken directly into the aircraft.

or additional data on Stratos' line of air conditioning systems, write to:

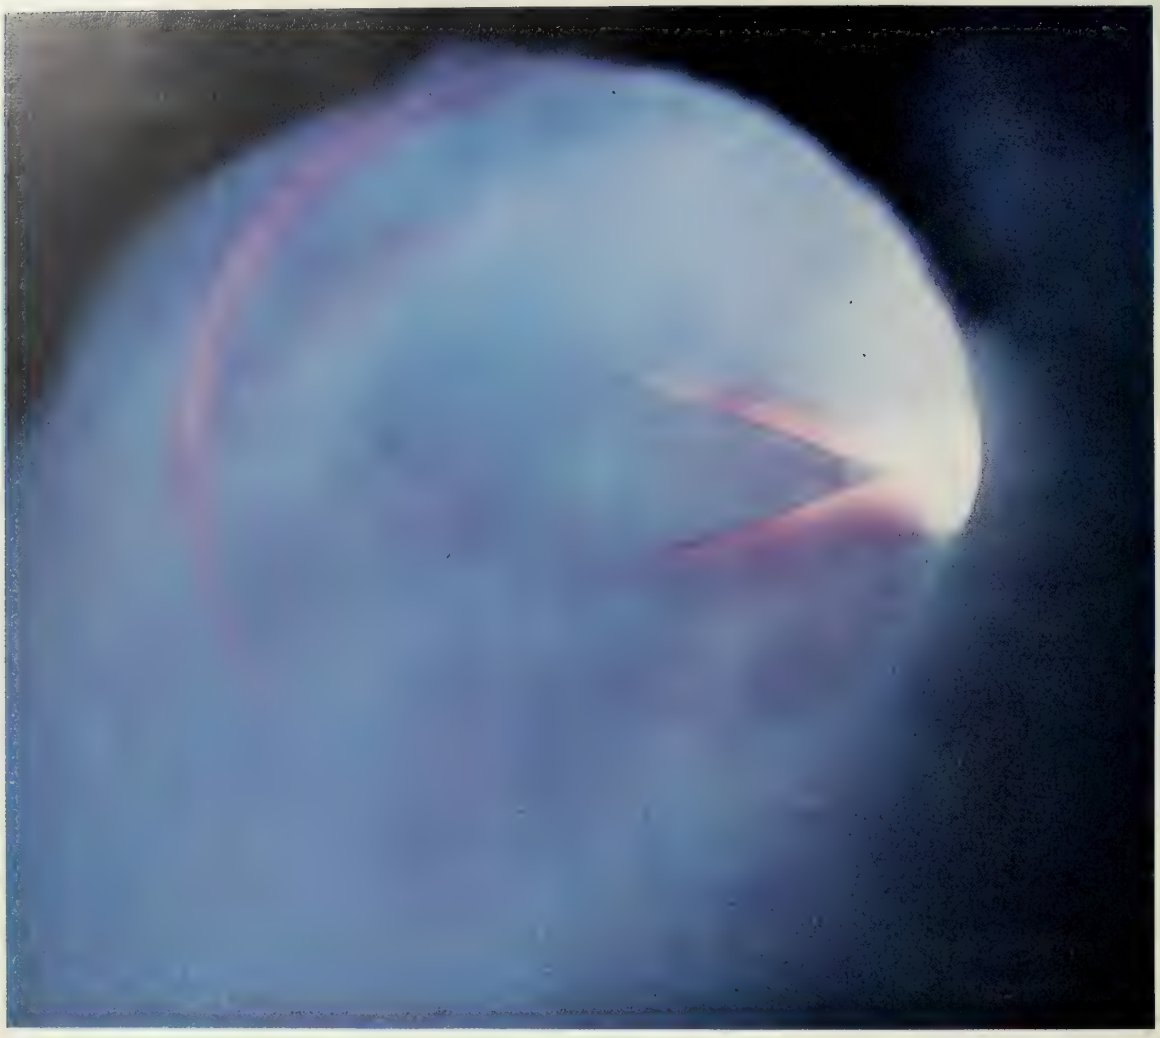
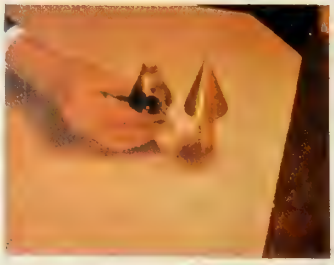
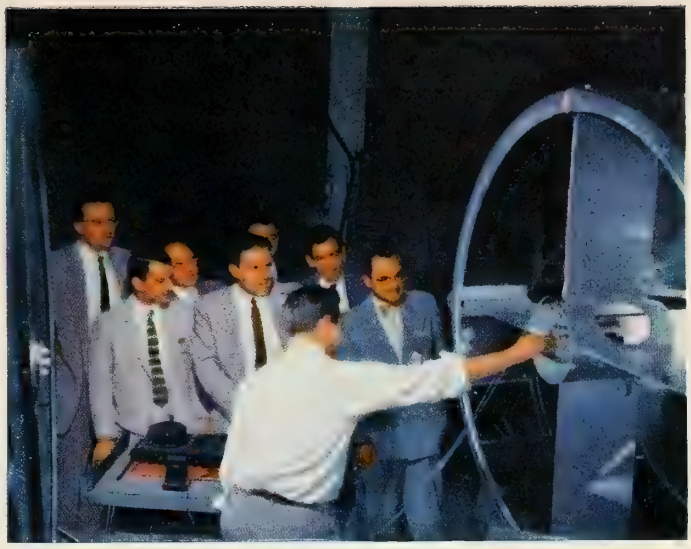
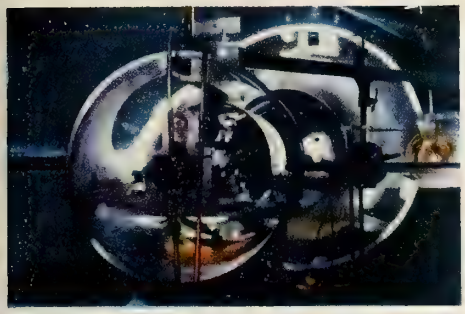
New sciences require new tools. In turn, new t
reveal new sciences. These colors of tomorrow
shot for m/r in the new Aerosciences Laborator
General Electric Company's Missiles and Ordna
Systems Department at Philadelphia. The m
million dollar facility, to be finished this fall,
an original purpose to study the aerodynamic
materials problems of hypersonic flight. Alre
however, Dr. Leo Steg (above), the lab's e
getic young director, admits that not even he
define the limits of these tools that probe the
known. The dull thud of a shock tube bursting
diaphragm, the devil's spectrum of a plasma je
these are the sounds and colors of escape, Mars
bit, return and reentry, of research in a new

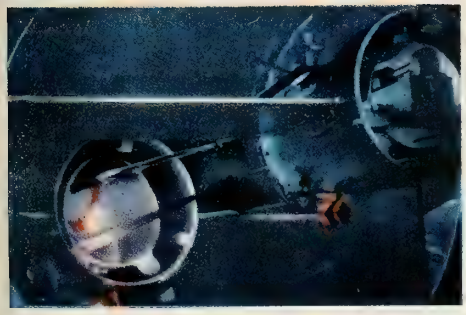


Like a ring-sight zeroing in on the future, the carbon arc-powered solar furnace above can concentrate 2700°C heat in the test area. To the far left, opposite, a compressed asbestos test cone glows, flares and disintegrates under the 12,000°C plasma blast from a water stabilized arc. Moving right, the next two pictures show the same jet with a graphite expansion nozzle in place. AF Office of Scientific Research's Col. Wm. O. Davis says such a stream of ionized particles exhausting through magnetic coils may soon provide basic ion propulsion know-how. Next, a copper sample waits its turn; in an instant glows red; then melts, spalls and vaporizes in tell-tale copper green. This arc, a joint MOSD—Chicago Midway Laboratories development initiated by GE's Dr. B. Levine, uses a half-inch electrode and 200 kw of DC power. Water swirling in the plastic annulus cools the unit, confines the arc and is vaporized and ionized into a plasma. The GE MOSD lab also boasts a liquid nitrogen stabilized arc using a one-half inch electrode and 200 kw. Possible later versions requiring several thousands of kw will offer versitility and a wider range of test conditions—tens of thousands of degrees centigrade and extremely high hypersonic velocities.

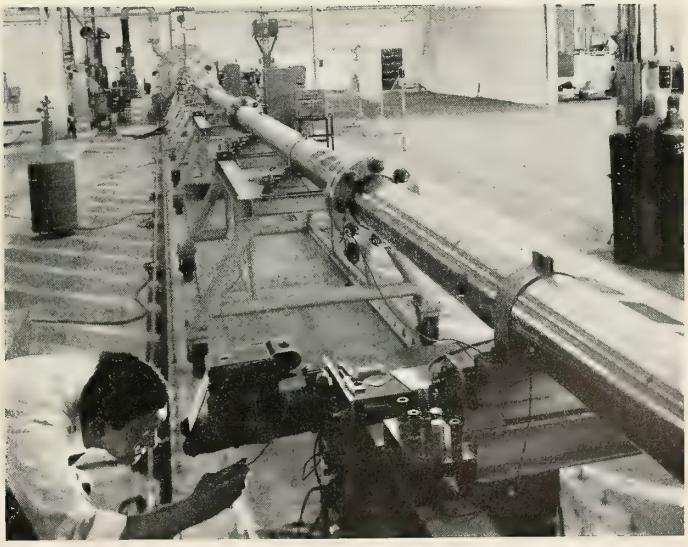








Not man's first assault on Saturn's ammonia atmosphere, but the moment of ignition of GE MOSD's liquid nitrogen "steam" as it pours from the test chamber. Even though liquid nitrogen's temperature is —195°C, the unit promises temperatures up to 12,000°C and more closely simulated atmospheric conditions. These arcs provide heat transfer rates on the order of 500 BTU per square foot per second. The surface temperature of the sun is approximately 6500°. In charge of developing this unit are Drs. John McGinn and Harold Wachman (white shirt). Note the heavy frost on the lead lines and swirl chamber. This equipment can provide test conditions for seconds or minutes, depending only on the length of the electrode. Note also, in the before-and-after shot, the beating a brass nose cone took from heat and blast in just a few seconds.



Mr. Jesse Metzger, MOSD's solar furnace researcher, sweats it out between heat source and target to explain a new technique to Aeroscience's associates (left to right): Dr. Wallace Warren, Dr. Wm. C. King, Jr., Mr. James Reid, Dr. Leo Steg, Dr. Harold Wachman, Dr. Joseph Farber and Mr. Clifford Mannal. Actually, the name Aeroscience will probably be discovered to be a misnomer. The potentials of some of these tools has been described as "fantastic." It seems certain that their contribution to man's knowledge of the basic state of his universal environment will far exceed the current confining limits of this definition.

A bit hot for marshmellows, solar furnace has melted its way through a one-eighth inch thick sheet of stainless steel (top). Again looking into the white-hot heart of this inexpensive laboratory tool, a lucite test sample melts from its probe in a few seconds. And to the right center, an epoxy resin slug glows red hot in scientist's tongs. Slug has been removed before destruction in order to evaluate rate of deterioration and changes in material's chemical and physical properties under high heating. To the right, MOSD's most expensive Aeroscience research tool now in place is this six-inch diameter shock tunnel. Still building up to full power, it has already produced Mach 10 shock waves. A unique feature of this installation is the expansion throat at the far end, permitting study of large-scale models. Contemplated for addition to the array is an electric arc discharge accelerator, theoretically capable of model velocities in the hyper-hypersonic range—beyond the realm of known requirements.

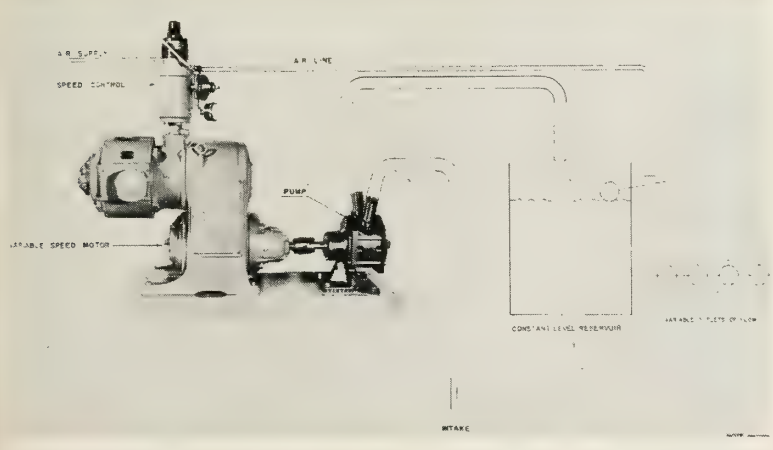
NEW MISSILE PRODUCTS

MISSILE TRACKING SYSTEM



First completely mobile optical tracking system, capable of photographing an object 2″ x 7″ at an altitude of 4 miles, has been delivered to the Air Research & Development Command. System will soon undergo range evaluation tests at ARDC's Armament Center, Eglin AFB, Fla.

Called Telescopic Photographic Recorder (TPR), the 6-ton system will be used to photograph the flight history of missiles, aircraft and bombs. It will record documentary information such as altitude, spin rates and correlated time data. TPR was designed and built by the Perkin-Elmer Corp.

TPR can be readily moved to any desirable site and can be operated either remotely or by operators. It consists of a 9′ long, 100″ focal length reflecting telescope equipped with 70 mm motion picture camera, two sighting scopes, controls, electronic and hydraulic equipment. Primary telescope is a 3-in-1 system.

Circle No. 207 on Subscriber Service Card.

PUMP-MOTOR SET

Variable flow rate pump-motor set designed specifically for pilot plant, laboratory or process work where controlled and varying rates of flow of corrosive fluids and abrasive slurries are required is being marketed by Vanton Pump & Equipment Corp.

The pump is driven by a variable speed source so that a relatively linear relationship between speed and output can be obtained. This offers a practical and exact way of varying the rate of flow.

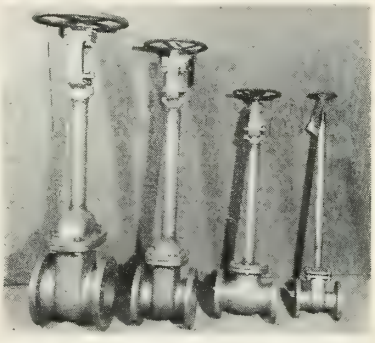
The sensing and controlling portion of the system is an air signal operating at an instrument pressure of 3 psi to 15 psi. The signal pressure controls the power air through an amplifier, thus controlling the rpm of the pump drive.

Pump has no stuffing boxes or shaft seals and the fluid conveyed is isolated to contact only materials used in the flexi-liner and body block.

Circle No. 265 on Subscriber Service Card.

FLAME-RETARDANT LAMINATE

A new flame-retardant glass epoxy laminate, featuring excellent flame and heat resistant properties, has been developed by Continental-Diamond Fibre Corp. When removed from flame laminate will not continue to burn because of self-extinguishing characteristics.



Laminate can be used continuously at temperatures up to 300°F. Above this mark it can be used intermittently. Available in plain form for power applications and metal-clad form for printed circuitry. Can be obtained in sheets ranging from .010″ to 1″ in thickness.

Circle No. 200 on Subscriber Service Card.

STAINLESS STEEL VALVES

Cooper Alloy Corp. has developed a line of stainless steel gate and globe valves for handling liquid oxygen and other extremely low temperature liquids.

Valves which operate at around —300°F and pressures of 150 psi to

600 psi are designed with extended bonnets to permit the use of heavy insulation between the operating mechanism and the pipe line. This serves to prevent heat pick-up into the valve and its contents and to allow free movement of the operating mechanism.

Furnished with Teflon chevron packing, valves are available in both gate and globe designs from ½″ to 12″.

Circle No. 218 on Subscriber Service Card.

NUCLEAR ELECTRIC TIMERS

A small, lightweight electric timer suitable for use in time delays, missile destructors, pilot ejection systems, alarm systems, and warheads uses a nuclear battery as its power source.

Called Betachron, the unit was developed by the Moos Division of Universal Winding Co., Inc. The timer has a shelf and use life of over 25 yrs. and is capable of operating reliably over wide ranges of temperatures, acceleration and vibration. Suitable for use in missile systems where time delays from microseconds to 40 hrs. are required with an accuracy of ±3%.

Timer is capable of delivering energy pulses up to 250,000 ergs, is supplied and encapsulated in a metal case with standard connectors at the output. Heart of timer is nuclear battery which converts nuclear energy directly into electrical energy.

CONSTANT DAMPING GYRO

A new rate gyro, Type JRT, has been developed by the Boston Division of Minneapolis-Honeywell. Instrument measures absolute rates of rotation in inertial space. Damping is electro-mechanically controlled to maintain a constant damping ratio over the entire operating temperature range of —65°F to 175°F.

The rate gyro is designed specifically for flight control of long-range missiles and for instrumentation in missiles and aircraft where ambient temperatures are not controlled and at the same time where

low threshold, minimum hysteresis, excellent linearity, high natural frequency and ruggedness are essential.

Features include: excellent linearity, 25% of full scale; low hysteresis, less than .1% of full scale; low threshold, less than .01°/sec; microsyn pickoff, variable reluctance type providing infinite resolution and high signal-to-noise ratio; full scale rate, up to 1,000°/sec; full scale output, up to 12v; withstands 100g shock, 15g to 2,000 cps vibrations; size 2 7/64" diameter, 4 5/16" long; weighs 2 lbs.

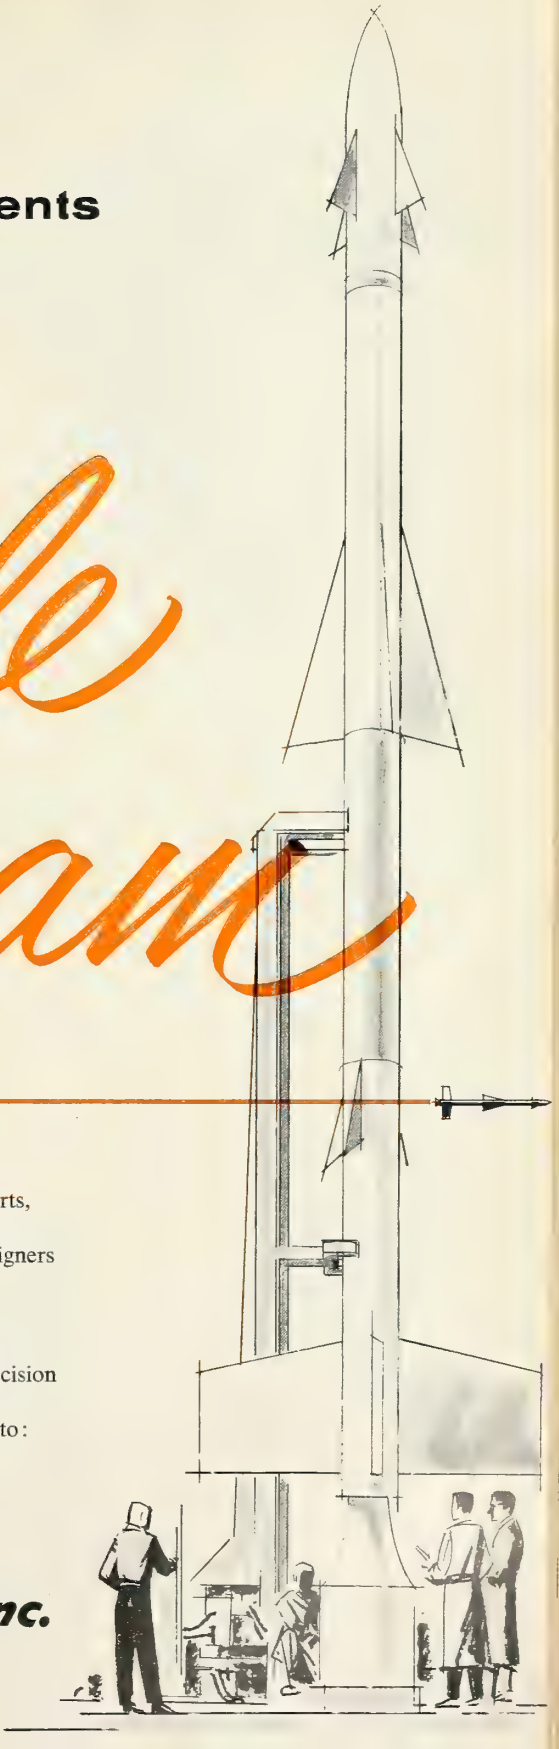
COUNT RATE METER

A logarithmic count rate meter build to the latest ORNL specification Q-1454-B is being produced by the Victoreen Instrument Co.

Based on the Cooke-Yarborough circuit, Model 727 is a wide-range instrument for use with all types of radiation



detectors. Applications include gamma monitoring with scintillation counter, beta-gamma monitoring with Geiger counter, and gamma ray spectrometry.

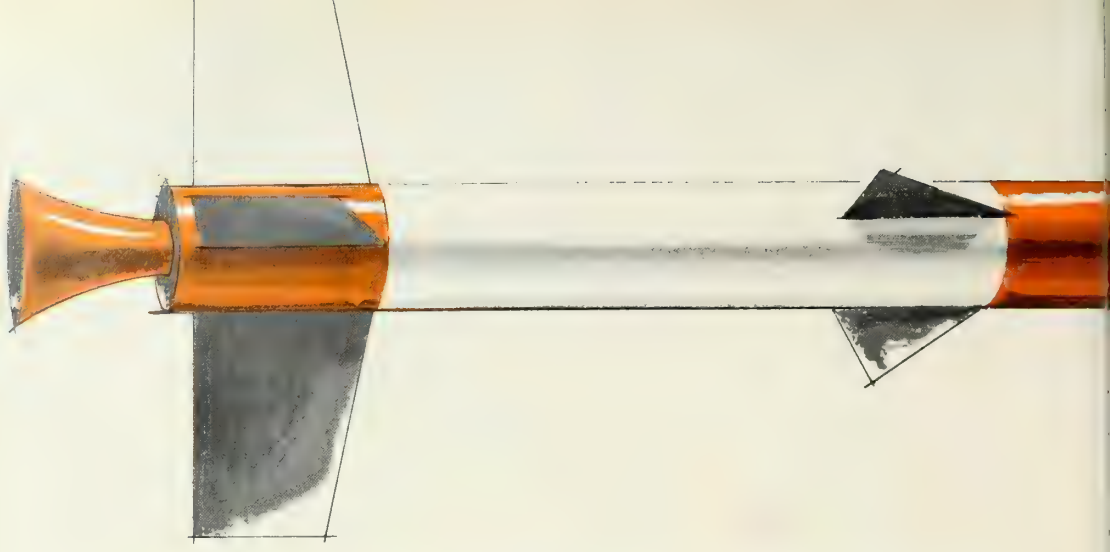
Meter eliminates need for manual or electrical switching as is required in linear-type rate meters. Range is from 10

Leader in Jet Components

can help speed your

Missile Program

Experience gained in producing over 100,000,000 forged parts, stainless steel weldments, and assemblies for all jet engine manufacturers is available now to designers and manufacturers of missiles.



Let us discuss your projects and your needs with you now. Your missile can then have the benefit of what the Jet Division has developed for the jet-engine industry . . . precision forgings, high-temperature alloys, resistance-welded stainless steel assemblies. Write or phone today to:

MISSILE PROJECTS DEPARTMENT

JET DIVISION

Thompson Products, Inc.

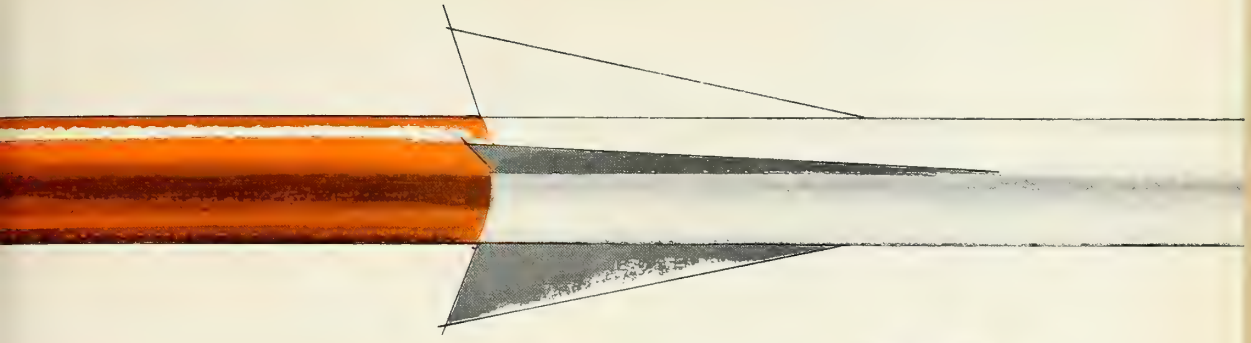
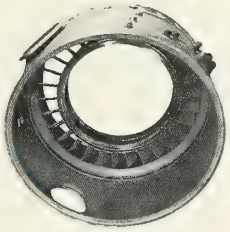
for your missile program...

complete engineering and test facilities to augment your manpower



The men at the Jet Division who helped develop forgings and stainless steel weldments for jet engines are ready now to work with missile engineers on projects using their experience and talents.

You can use their services in the development of air-frames, tanks, and other structural components of missiles. You can also use their experience with metals at high temperatures in the design of your missile power-plants and skin-surface components.



A Jet Division engineer will be glad to call at your convenience to discuss your projects, timetables, and requirements.

Tensile tests at elevated temperatures are run on various alloys in Jet Division labs to determine their strengths under missile equivalent operating conditions.

for your missile program...

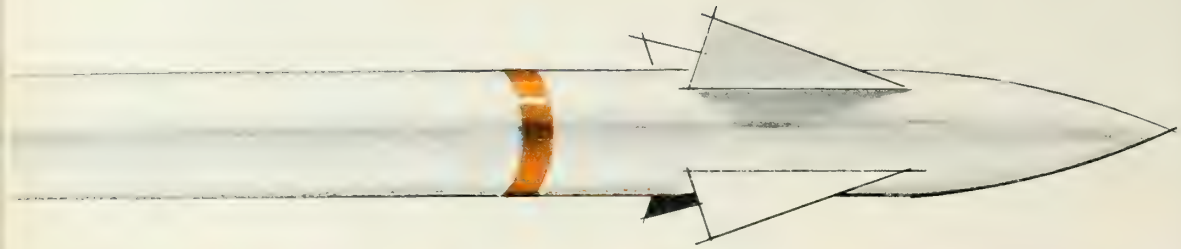
weldments in stainless and high-alloy steel and titanium made to your specifications

High-precision weldments that combine careful forming, all types of welding, and accurate placement of bosses and holes, can be designed and produced for your missile at the Jet Division.

Our experience in the production of titanium, high-alloy and stainless steel components for jet engines can give you a head start on your missile projects. Special Jet Division techniques of welding and stress-relieving provide maximum strength at minimum weight in metals that can resist the operating temperatures and stresses of missiles.

Let us discuss your weldment and machining requirements and show you how Jet Division engineering and production can quickly augment your own facilities.

MISSILE PROJECTS DEPARTMENT



JET DIVISION

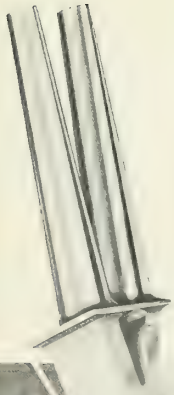
CLEVELAND 17, OHIO

Special welding procedures and jigs are used in welding service-stressed stainless and alloy steel components into a finished structure at the Jet Division.

for your missile program...

Forgings made to closest tolerances for high-temperature service

Starting in 1944, the Jet Division was the first manufacturer of high-precision forgings for jet aircraft engines.

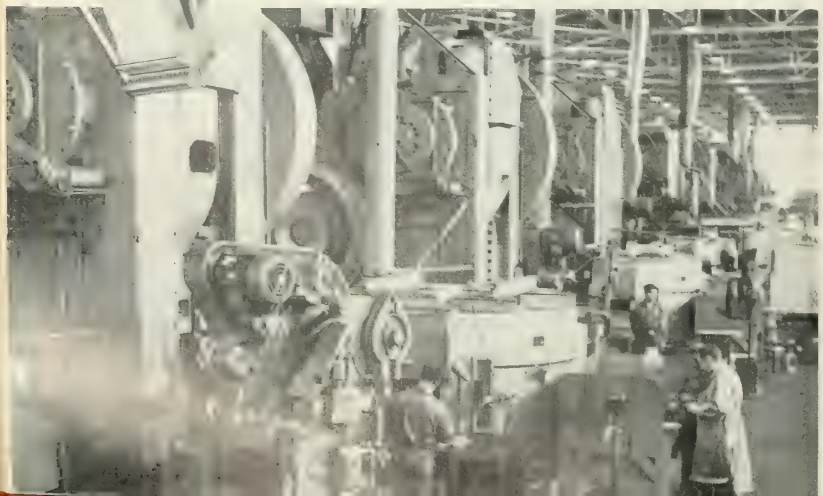


More forged parts of titanium, stainless and high-alloy steels for engines of every manufacturer have been made by the Jet Division than by any other producer.

Every jet engine manufacturer uses Jet Division forged parts.

Forged to extremely close tolerances and contours, precision parts produced by the Jet Division often require no costly machining before assembly. Their use in your missile can speed delivery, reduce finishing time, eliminate capital plant investment.

Complete machining and test facilities are also available for your missile subcontract work.



Our sales engineers will gladly discuss your missile project requirements at your convenience.

WRITE FOR FREE BOOKLET

The complete engineering and manufacturing facilities of the Jet Division are described in Booklet MI-57. Write on your company letterhead for a copy.

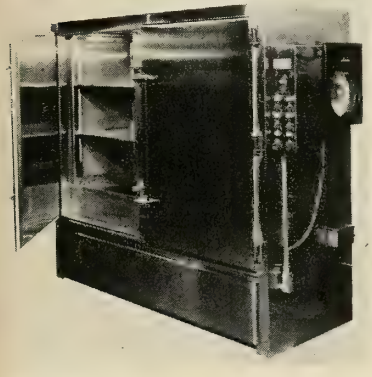
MIRROR BORESCOPE

Borescope developed by Lenox Instrument Co. permits complete internal inspection of tanks, vessels, combustion chambers and other equipment by means of an adjustable mirror which can be controlled by a hand-wheel to permit scanning from restrospective through right

angle to forward oblique.



Large field of view offered by instrument makes it easier to detect flaws, pits, cracks or deterioration to assure perfection in manufacturing and maintenance. Borescope gives magnification of 10 power, a field of vision of 9" in diameter at a distance of 24", and has a viewing head with 13/16" diameter 100 watt lamp.

Circle No. 212 on Subscriber Service Card.

ENVIRONMENTAL EQUIPMENT

Labline, Inc. is producing a line of Environ-Cabs to simulate temperature and humidity conditions over a range of 20% to 95% relative humidity and temperatures from 40°F to 200°F, in four sizes—10, 20, 30 and 40 cu. ft.

Environ-Cabs are suitable for laboratories and plants where such tests must be run. Features are double-wall cabinets with interiors and exteriors of 1808 stain-

less steel, insulated with Fiberglas, perforated diffuser walls for uniform air flow, dual blowers, dual hydraulic thermostats for temperature control, silicone door gaskets, adjustable shelves.

Humidity pan with heaters and automatic water level supplies the necessary humidity conditioners. Where required,

IERC's FREE TUBE SHIELD GUIDE helps you improve electron tube reliability—

—provides information you need to properly match over 1,400 sizes and types of electron tubes and heat-dissipating tube shields for best cooling, retention and protection against shock and vibration!

New 20 page IERC Heat-dissipating Tube Shield Guide has been carefully and accurately compiled in answer to many hundreds of Electronic Engineer suggestions and requests for just such a practical Guide. New design applications and retrofitting of electronic equipments with IERC Heat-dissipating Tube Shields (for the excellent cooling, extended tube life and reliability they provide) created the need for this type of professional information – plus another "first" for IERC – *the first reference manual of this type* to the electronic industry!

automatic temperature recorders, controllers and programmers may be installed. Thermopane observation windows, terminal boards for elecrtical testing, penetrations for pipes, wires, etc., are optional.

Circle No. 204 on Subscriber Service Card.

MINIATURE SWITCHES

Airtron, Inc. has developed a miniature waveguide switch for applications requiring minimum size and weight. Switch provides rapid switching of signals from any one of three positions to either of the remaining two and will not change to another position upon failure of power supply.

Electrical characteristics of the 1" x .5"-size unit includes a frequency range of 8,500 to 9,600 mc/sec with a maximum VSWR of 1.10 and minimum isola-

tion of 40 db. Maximum switching time is .25 sec. for 240° operation and .15 sec. for 120° operation. The universal switch operates at 3 amperes maximum at 28 vdc nominal and employs R.F. and pressurized fittings built into the switch, giving up to 20 lbs. of pressurization throughout.

Available in Xs and X_L band series, switches are of rotary channel type using a circular bend in the rotor and a broadband internal choke design.

Circle No. 210 on Subscriber Service Card.

MAGNETIC COUNTER

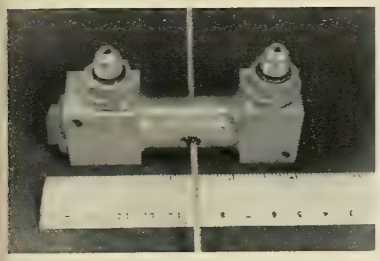
Abrahms Instrument Corp. is marketing improved models of their 3- and 4-digit magnetic counters for use in aircraft and missile applications.

Available in additive or subtractive types with manual reset wheels, the counters record pulses accurately up to 1,200

counts per minute. Actuated electromagnetically, counters can be connected in vacuum tube plate circuits or operated by any contacting device.

A variety of mounting methods is possible and units can be supplied with

or without panel mount cases.



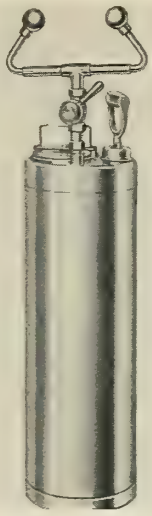
Snap-door on front of case allows convenient resetting. Counters available for all common voltages from 6 to 110 vdc. Three-figure counter measures ⅞" x ⅞" x 2", weighs 2 oz.

Circle No. 216 on Subscriber Service Card.

CABLE CUTTER

A ballistically-operated cable cutter with self-contained cartridges has been developed by Stanley Aviation Corp. Triggered by low incoming gas pressure, the unit contains two independently fired cartridges, either of which produces sufficient force to sever a ⅛" steel cable.

Weight is .45 lbs., unit measures, 4" x 1" x 2¼". Device is applicable to



any system requiring instantaneous, reliable cutting of cables, wires, tubes or rods.

Other models are designed to operate from mechanical or electrical signals, rather than pressure input, and provide for variation in mounting position, cable orientation and changes in angular relation of input connections.

Circle No. 219 on Subscriber Service Card.

EYE-WASH FOUNTAIN

A portable emergency eye-wash fountain, for instant eye first aid where normal water supplies are not available, is being manufactured by Haws Drinking Faucet Co.

Model 8950 is designed for use by crews working in remote areas. The corrosion-proof stainless steel tank has a carrying strap and holds three gallons of water instantly avialable to flood the eyes and wash away dangerous substances or particles. Specially designed fountain heads project water into the eyes with a soft, flushing stream.

Pressure is build up within the tank by means of the large pump handle. Pressure maintained for an 8-hr. period. Weight is about 40 lbs. loaded, 15 lbs. empty.

Circle No. 217 on Subscriber Service Card.

PROGRAMMER COUNTER

Precision-made devise turns on and off test apparatus whose limits are sensed by strain guages, thermocouples or other transducers that have a maximum output not exceeding 100 mvdc. Instrument has been developed by Spar Engineering & Development, Inc.

Unit eliminates need for manual control of test cycling and simplifies setting up of equipment each time test is to be run. The Spar program counter is said to be a stable, precision mv electronic relay having adjustable energizing and release thresholds and DPDT 15 amp contacts. Its two, adjustable, stable thresholds provide for precise selection of

LENOX
DETECTS HIDDEN DEFECTS

For internal visual inspection, LICO BORESCOPES are dependable over the years.

Use a precision made LICO BORESCOPE for accurate inspection of tubes, hollow forgings, cylinders, combustion chambers, blind rivets, etc.

- LICO optical systems give a wide field of view at 3-4 power, or any desired magnification.
- Four self-luminous, interchangeable viewing heads are available:
  - **Circumference:** for rapid panoramic inspection
  - **Prismatic:** for close angular viewing
  - **Forward:** for blind bores
  - **Special:** for various angles of view
- Ultra-violet light can be built in for Magnaflux inspections
- LICO instruments are available in one piece or in sections
- Special designs can be readily fabricated from stock parts

LICO BORESCOPES are widely used throughout industry in sizes from a small quill to 2¾" in diameter and from a few inches to 85 feet in length. Write, wire or call for our bid on an inspection instrument to meet your needs.

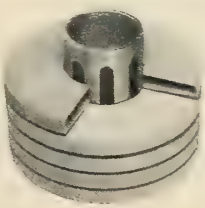
NEW *Harmeco* PURAFLO FILTERS



Pneumatic Type for Compressible Gases—Pressures to 6,000 lbs.

Harmeco PURAFLO Filters are available in various case designs to suit any piping requirement for filtering helium, nitrogen and other compressible gases at porosity ratings of 2, 5, 10, 20 or 40 microns or coarser. Interchangeable multi-tube sintered stainless steel wire wound elements or strainers are optional. Case is carbon steel forging; stainless steel, monel or other materials as specified.

ELEMENT MANIFOLD PIPE ASSEMBLY

Double tapered one piece Harmeco hollow sintered bronze disc elements provide deep uniform, dependable filtration. Spacing between the discs is uniform when assemblies are stacked and sealed in ported manifold pipe. One piece element design eliminates slip fits or organic bonding materials. The double tapered, hollow disc design prevents blocking off of surface area due to possible cocking of the elements on the manifold pipe. Result: greater filtering area; uniform porosity control; clean decontaminated products.

BOEING PHOTO

. . . ARE PROTECTED BY THE B&H JETCAL® ANALYZER

Two of the most important factors that affect jet engine life, efficiency, and safe operation are *Exhaust Gas Temperature (EGT)* and *Engine Speed (RPM)*. Excess heat will reduce "bucket" life as much as 50% and low EGT materially reduces efficiency and thrust. Any of such conditions will make operation of the aircraft both costly and dangerous. The *JETCAL Analyzer predetermines* accuracy of the EGT and (interrelatedly) Tachometer systems and isolates errors if they exist.

The *JETCAL* ANALYZES JET ENGINES 10 WAYS:

1) The JETCAL Analyzer *functionally* tests EGT thermocouple circuit of a jet aircraft or pilotless aircraft missile for error *without running the engine or disconnecting any wiring*. GUARANTEED ACCURACY is ±4°C. at engine test temperature.

2) Checks individual thermocouples "on the bench" before placement in parallel harness.

3) Checks thermocouples within the harness for continuity.

4) Checks thermocouples *and* paralleling harness for accuracy.

5) Checks resistance of the Exhaust Gas Temperature system.

6) Checks insulation of the EGT circuit for shorts to ground and for shorts between leads.

7) Checks EGT Indicators (in or out of the aircraft).

8) Checks EGT system with engine removed from aircraft (in production line or overhaul shop).

9) Reads jet engine speed while the engine is running with a guaranteed accuracy of ±0.1% in the range of 0-110% RPM. Additionally, the TAKCAL circuit can be used to trouble shoot and isolate errors in the aircraft tachometer system.

10) JETCAL Analyzer enables engine adjustment to proper relationship between engine temperature and engine RPM for maximum thrust and efficiency during engine run (Tabbing or Micing).

ALSO *functionally* checks aircraft Over-Heat Detectors and Wing Anti-Ice Systems (thermal switch and continuous wire) by using TEMPCAL Probes.. Rapid heat rise . . . 3 minutes to 800°F! Fast cycling time of thermal switches . . . 4 to 5 complete cycles per minute for bench checking in production.

Tests EGT System Accuracy to ±4°C at Test Temperature

(functionally, without running the engine)

Tests RPM Accuracy to 10 RPM in 10,000 RPM (±0.1%)

The JETCAL is in worldwide use . . . by the U. S. Navy and Air Force as well as by major aircraft and engine manufacturers. Write, wire or phone for complete information.

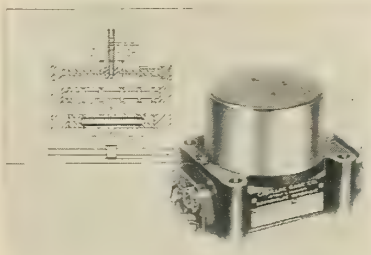
TANTALYTIC CAPACITORS

New "King Size" high temperature tantalytic capacitors for low voltage direct current capacitors with high microfarad values in a small space have been added to General Electric's Capacitor Department line. Three rectangular case sizes with similar base dimensions of 1.316" by 0.75" are being produced.

Heights vary from 1.375" to 2.5" with typical capacities of 1000 mico-



farads at 30 volts to 100 microfarads at 20 volts. The capacitors are rated for 1000 hours operation at 125°C with not more than 20 percent loss from 25°C capacitance after the 1000 hour period.

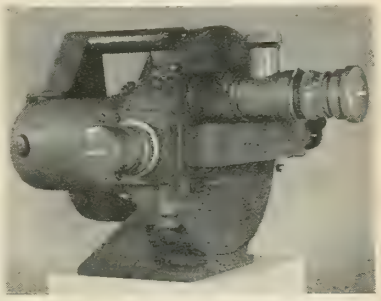
ELECTRO-HYDRAULIC VALVES

A new series of Electro-Hydraulic Servo valves, known as the FC200 series,

has been developed by Cadillac Gage Co. Series is comprised of three models.

Valves represent a marked departure from previous design concepts and are capable of functioning reliably under the rigorous operating and ambient conditions encountered in modern high performance aircraft and missiles. They utilize a closed loop hydraulic control circuit to position the output stage and are of a completely balanced push-pull construction.

No springs are incorporated in the design. The valves have a minimum of moving parts, incorporate a single large capacity filter element to protect the control stage, and are of "dry coil" design.

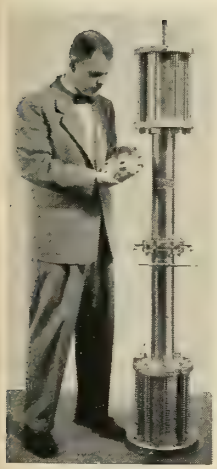


Circle No. 238 on Subscriber Service Card.

HIGH SPEED CAMERA

Fastex high speed motion-picture and oscillographic camera and a 16 mm projector and a motion picture missile camera have been developed by Wollensak Optical Co.

Fastex-WF-17 combination high speed motion picture and oscillographic camera was designed to record both mechanical and electrical data on the same film. It is particularly useful where studies of short duration are required. Camera takes 100' daylight loading spools, has speed ranges from 150 to 8,000 pictures per second, and can be used for either picture or oscilloscopic recording independently.



The projector was developed for the study and analysis of subjects filmed by high speed cameras. Films can be pro-

jected without flicker as slowly as 2 frames-per-second. In addition, normal speed of 16 frames-per-second, frame by frame or still picture may be shown.

The Fastair high speed missile camera, in addition to its rugged construction capable of withstanding high g loads,

Now . . . shock test with a controlled 10,000-pound thrust

The HYGE shock tester, manufactured and marketed by CEC under license from the Convair Division of General Dynamics Corporation.

Simulate actual service conditions and test shock resistance of parts and assemblies. Make *repeated* tests accurately.

The new HYGE shock tester will produce specific acceleration and/or deceleration wave forms for desired durations.

In theory, it can produce a build-up rate of 200,000 g's per second from zero to peak acceleration, with a pattern free of high-frequency transients.

HYGE can be used to develop controlled impact shocks from 2,000 to 6,000 g's—accurately.

HYGE is available in standard types, or in a "kit" of modular components. Send for Bulletin P4-70 for details.

CENTURY MODEL 409D RECORDING OSCILLOGRAPH

Numerous agencies engaged in the manufacture and evaluation of missiles have turned to the Century Model 409D Recording Oscillograph as a reliable means of collecting missile performance and control data.

On-board mounting eliminates the necessity for the costly and often not reliable RF link.

The ruggedness and reliability of this 12-channel oscillograph have been demonstrated many times. One agency reports having recovered 42 satisfactory record rolls out of 43 firings. Another, using special mounting configuration, reports recording at 60 G's without damage.

This 13 lb. instrument is compact enough to be installed in most missiles and all electrical connections including remote control are accomplished through a single multi-pin AN connector.

severe vibration, impact and shock, will accept 50′ and 100′ daylight loading magazines. This feature eliminates one of the photographer's major problems in location work.

Circle No. 259 on Subscriber Service Card.

MAGNETIC COUNTER

Model MCRP-700 by Photocon Research Products is a compact, high-speed, precision counter developed to add or

subtract electrical pulses with optional microswitch control at zero level—featuring electrical reset to any predetermined number.

The high-speed lightweight armature, which actuates the counting mechanism, is dynamically balanced to provide accurate counting under severe vibrations.

The MCRP-700 can be furnished as a three, four, or five digit counter with any combination of add, subtract, and microswitch control at zero level.

Circle No. 249 on Subscriber Service Card.

PRESSURE CONTROLLER

Bellofram Type air gauging manostat is said to give precise downstream pressure control over wide supply pressure variations. It does not drift with time or with periodic shutdowns. It remains precisely stable through tempera-

ture changes as well as supply or flow variations.

Manufactured by Bellofram Products Corp., the manostat utilizes an extremely high gain servo system with main valve action controlled by a pilot nozzle which in turn is activated by slight pressure variances. Instantaneous adjustment

of controlled pressure is assured by the small relative movement required between the pilot valve and its seat in order to initiate great changes in main valve action.

To eliminate exhaust valve "pick-up" on dead-end service and initial drop-off, pilot pressure is bled directly to atmosphere rather than downstream.

Manostat's entire measuring element, including the pilot valve, embodies highly elastic metallic parts having practically no hysteresis or permanent deformation under any working conditions.

Resolution is one-part-in-10,000 of range, and repeatibility is usually less than one in 5,000 of range.

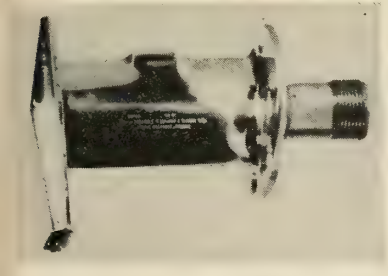
Available in ranges of 2-25 and 3-36 psi in 1.8" and ¼" pipe sizes.

Circle No. 264 on Subscriber Service Card.

SAMPLING SWITCH

A precision switch having a hermetically sealed case for high altitude mili-

tary and commercial applications has been developed by General Devices, Inc.



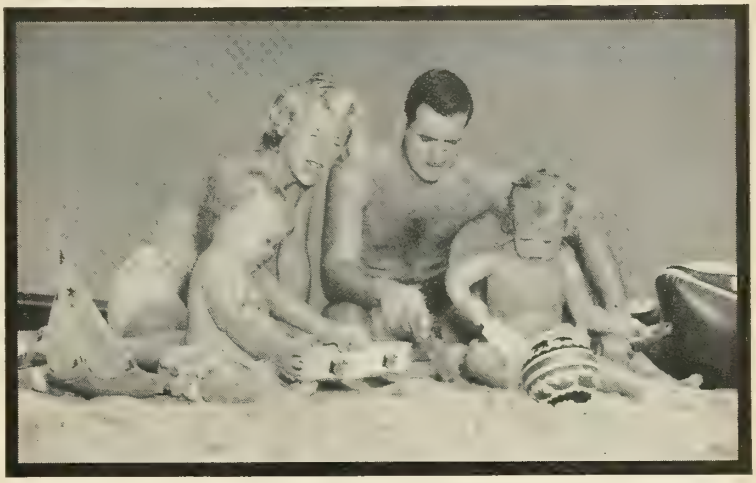
The switch has up to two poles with 30 non-shorting channels per pole. It is driven by either 28 vdc motor with a governor, arc-suppressor and a R.F. filter or a 115 v, single phase, 400 cps hysteresis synchronous motor.

Dimensions are 2.75" x 4.94" x 3.87". Typical applications include high altitude telemetry systems, multi-channel data systems, error indicating systems, etc.

Circle No. 247 on Subscriber Service Card.

TEMPERATURE PROBE

Rosemount Engineering Co. claims its Model 102 is the fastest total temperature



probe designed specifically for flight test applications. Time constant for the probe is less than 25 milliseconds under most conditions of operation.

The 102 exhibits extremely small recovery errors, namely, less than .1% of the absolute temperature for supersonic flight, and even less for subsonic flight.

Engineers:

Stimulating work . . . Stimulating play just minutes apart

This is Honeywell in Minneapolis . . . an ideal atmosphere for the engineering mind. At work; outstanding technical facilities plus the opportunity to work on today's most advanced electronic projects, a chance to work in a small group, guide your own project, get the recognition you deserve.

And in Minneapolis, just minutes from your work, 22 lakes and 151 natural parks. Swimming, fishing, boating . . . year-round outdoor play for you and your family, good schools, theatres and shopping, too!

At Honeywell you move ahead quickly. This fast growing company, already world leader in automatic controls, has more than doubled sales in the last five years, increased its engineering force over 100%. In such a company, promotions open quickly. At Honeywell, they come *from within*. You start at a first-rate salary and it's *just the start*.

Career opportunities for:

Design of the unit protects the element from flying particles. This is done by removal of internal boundary layer air, thereby avoiding the usual upstream particle deflector which is slow in response and contributes a slow transient into the response of ordinary "fast" designs, the company reports.

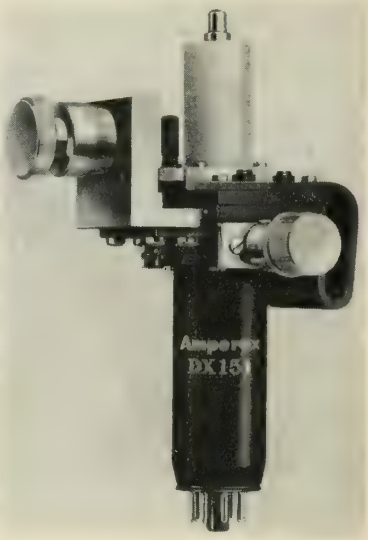
This design eliminates all but the finest water droplets. Further testing is expected to show dry adaabatic readings in rain.

Model 102 probe has 50 ohm platinum resistance thermometer element, and has excellent uniformity of calibration. The element may be easily replaced and repaired at low cost. The element also has long electrical leakage paths for minimum dependence or dampness.

Circle No. 237 on Subscriber Service Card.

HEAT TREATABLE ELECTRODE

Eutectic Welding Alloys Corp. has developed a fully heat treatable all-position electrode formulated specifically for fabrication of chrome-moly steel and other high tensile alloy steels.



Featuring ease of application regardless of current or position, "Low Amp" EutecTrode 71 ac-dc is designed mainly for low alloy steels, particularly the 4130, 4140 and 8630 grades. Deposits have similar heat treating characteristics as the base metal.

The electrode has a deposited tensile strength of 100,000 psi. Deposits are fully heat treatable. Specific uses for spatter and clag interference-free Eutectrode 71 ac-dc include fabrication of tanks, containers and vessels for high pressure work.

Circle No. 243 on Subscriber Service Card.

KLYSTRON

A new 4mm klystron tunable over a range of 6 kmc from 65.5 to 77.5 kmc

has been announced by Amperex Electronic Corp. The DX151 waveguide-output reflex klystron has an output of 40 milliwatts at band center and 10 milliwatts across the band.

Oxide coated cathodes are used and operate at 2 to 4 amps per square centimeter and are said to give long life. Heater power needed is 0.4 amperes at 10 volts ac or dc. Electrostatic focusing is used.

Circle No. 228 on Subscriber Service Card.

SNAP-ACTION SWITCH

Milli-Switch Corp. has developed a hermetically-sealed high-amperage snap-action switch which is said to insure reliability and performance because of a one-piece spring.

Model BHA-HS has an electrical rating of 10 amperes at 30 vdc resistive, 8 amperes at 30 vdc inductive and 10 amperes at 125 vac. Temperature range is —67°F to 268°F; operating force, 30 oz. maximum to 4 oz. minimum release force; vibrations, 55 to 4,000 cycles per sec.; shock, 75g.

Contacts are fine silver, 24 karat gold-plated; terminals are screw type 24 karat gold-plated over silver plate. Altitude to 100,000 ft.; life is 250,000 cycles minimum mechanical. The mounting bracket is corrosion resistant.

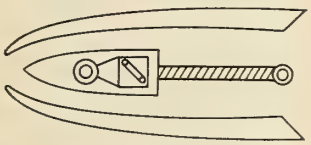
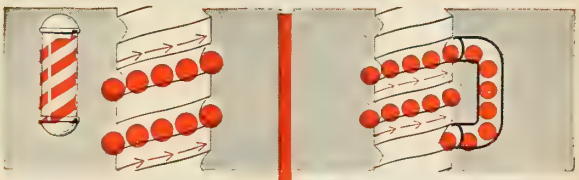
FAIL-SAFE ACTUATION



for guidance and control in difficult environments with SAGINAW b/b SCREWS and b/b SPLINES

TYPICAL APPLICATIONS



Control surface actuators

Nose cone positioners

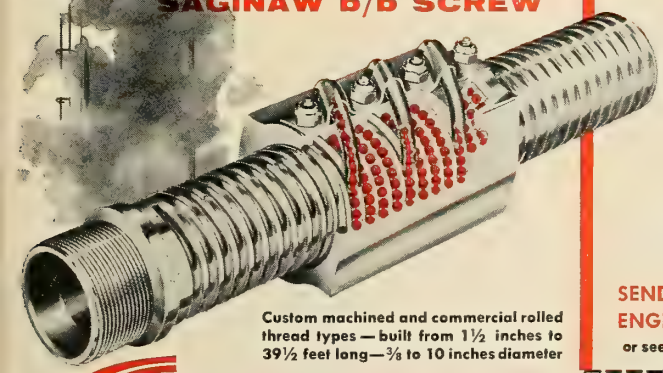
Evelon positioners • Afterburner controls • Speed brake actuators • Rocket engine displacement actuators • Clamping mechanisms for missile boosters • Fuel controls (3-dimensional cams) • Black box tuning devices—telemetering and guidance systems • Antenna coupler tuning mechanisms

Nut *glides* on steel balls. Like stripes on a barber pole, the balls travel toward end of nut through spiral "tunnel" formed by concave threads in both screw and mating nut.

At end of trip, one or more tubular guides lead balls diagonally back across outside of nut to starting point, forming closed circuit through which balls recirculate.

1 VITAL POWER SAVINGS. With guaranteed efficiency of 90%, Saginaw b/b Screws are up to 5 times as efficient as Acme screws, require only ⅙ as much torque. This permits much smaller motors with far less drain on the electrical system. Circuitry is greatly simplified.

2 SPACE/WEIGHT REDUCTION. Saginaw b/b Screws permit use of smaller motors and gear boxes; eliminate pumps, accumulators and piping required by hydraulics. In addition, Saginaw b/b Screws themselves are smaller and lighter. Units have been engineered from 1½ in. to 39½ ft. in length.

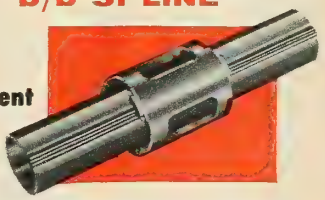


3 PRECISE POSITIONING. Machine-ground Saginaw b/b Screws offer a great advantage over hydraulics or pneumatics because a component can be positioned at a predetermined point with precision. Tolerances on position are held within .0006 in./ft. of travel.

4 TEMPERATURE TOLERANCE. Normal operating range is from −75° to +275° F., but assemblies have been designed in selected materials which function efficiently as high as +900° F. These units are practical where hydraulic fluids have lost efficiency or reached their flash point.

5 LUBRICATION LATITUDE. Even if lubrication fails or cannot originally be provided because of extreme temperatures or other problems, Saginaw b/b Screws will still operate with remarkable efficiency. Saginaw units have been designed, built and qualified for operation without any lubrication.

6 FAIL-SAFE PERFORMANCE. Far less vulnerable than hydraulics. In addition, Saginaw offers three significant advantages over other makes: (1) Gothic arch grooves eliminate dirt sensitivity, increase ball life; (2) yoke deflectors and (3) multiple circuits provide added assurance against operating failure.



SAGINAW b/b SCREW

Custom machined and commercial rolled thread types — built from 1½ inches to 39½ feet long—⅜ to 10 inches diameter

SAGINAW b/b SPLINE

Averages 40 times lower friction coefficient than sliding splines

Radically increases efficiency of transmitting or restraining high torque loads; built from 3 inches to 10 feet long, ⅜ to 6 inches diameter

Outstanding opportunities for qualified engineers

SHORT TURNBUCKLE

A short turnbuckle which exceeds standard tensile and fatigue strength requirements has been developed by Voi-Shan Manufacturing Co.

One-third as long as the standard AN short turnbuckle, the new one, called

Cabuckle, has constant length for any adjustment. It can be installed and adjusted readily with standard tools, eliminates cable twist, and can be lock-wired.

Cabuckle assembly has three components: slotted sleeve with rolled external threads, a forged cross-piece, and a hex nut. One cable end is attached to the sleeve, the other to the cross-piece. Cable tension is adjusted by advancing the nut on the sleeve and the amount of available adjustment is visible at all times.

Voi-Shan, division of the Pheoll Manufacturing Co., is licensed by North American Aviation Co. to develop and manufacture Cabuckle, NAA designed Cabuckle to meet a space-limit problem in the flight control system for the F-100 fighter-bomber.

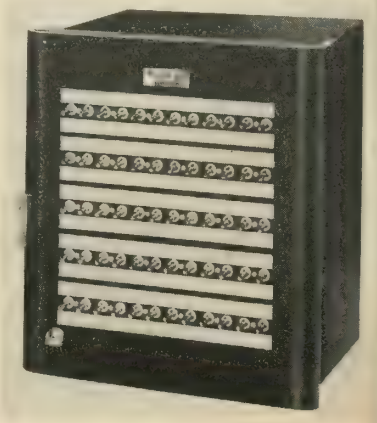
OXY-ACETYLENE REGULATORS



A new line of "Jet-Flow" oxygen and acetylene regulators for gas welding has been developed by Marquette Manufacturing Co.

The new regulators are offered in several price ranges and in many sizes, both single and two-stage. New design contains only four working parts, assuring long life and maintenance-free operation. Each regulator in the new line is "proof tested" in the factory under actual operating pressures to assure perfect operation.

Circle No. 236 on Subscriber Service Card.

PYROMETRY CIRCUIT SWITCHES

Thermo Electric Co., Inc. has developed a line of key-type selector switches

for connecting sensing elements to indicators, recorders or other instruments. Two-position and three position key switches with various pole arrangements are available.

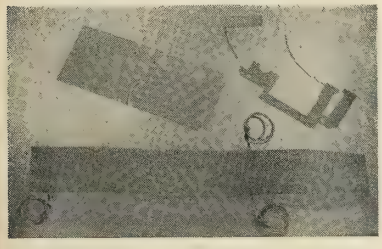
Cases containing the switches are moisture-proof and dust tight and suitable for wall or panel mounting. Case capacities range from 12 to 144 points for both thermocouples and resistance bulbs.

Circle No. 231 on Subscriber Service Card.

ANGLE ATTACHMENTS

A line of angle attachments, designed to simplify production fastening in close

quarters and hard-to-reach places, has been developed by Gardner-Denver Co.



Four attachments, for use with the recently developed line of Keller Tool air drivers, are heavy or light duty angle screw drivers and nut setters.

Newly designed Keller No. 2 air motors power both the 12G-2 series screw drivers and the 16G-2 series nut setters. These air motors, it is reported, provide more speed, increased power, low noise level and low maintenance.

Circle No. 245 on Subscriber Service Card.

WOVEN ELECTRIC HEATERS

Thin enough to fit into cramped instrument spaces, flexible enough to be bent around sharp corners, and availability in practically any physical shape are claimed to be advantages of a new group of heaters that permit wide design of flexibility in adapting electric heat.

Designated Pre-Fab Laminated Woven Electric Heaters, they are custom-made by Pre-Fab Heater Division, Chromalox, Inc.

Heaters may be insulated with silicone-rubber, Neoprene, natural rubber and synthetic rubber. Maximum heater surface temperatures are 150°F with natural or synthetic rubbers, 167°F with Neoprene, and 350°F with silicone-rubber insulation. They may be applied with adhesives and by bonding and clamping. Leads may be insulated with silicone, Teflon, neoprene or rubber, depending on the construction of the heated sections.

Widths of the Pre-Fab heaters range from ⅜" to 24", while maximum length

Another **DALMO VICTOR** *achievement*

Super-sensitive DV Nose Boom monitors the Navy's Regulus II

Chance Vought had a problem: Packaging a host of intricate equipment in a needle-thin boom to monitor the Navy's new guided missile, Regulus II. This "packaging" was additionally complicated by the requirement that to conserve storage space on board a submarine, the boom must fold pneumatically by remote control.

Dalmo Victor's engineering skill, acquired through development of airborne radar scanner designs, provided the answer!

The ten-foot DV pitot static boom, as accepted by the Navy, meets these most exacting design requirements and provides vital data, including airspeed and altitude, as well as angles of attack and yaw.

Long-recognized leader in airborne radar antennas, Dalmo Victor now applies its experience and skills to create missile components. Contact the nearest DV office for help in solving similar problems.

TRANSISTOR TRANSFORMERS

Seven new types of transistor transformers have been added to the United Transformer Corp's line of ultra-miniature DO-T units. The units weigh one-

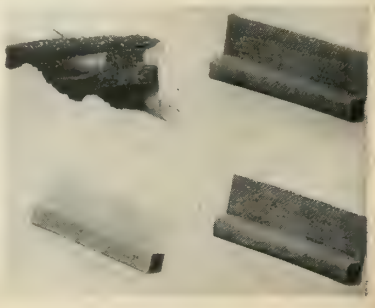
tenth ounce and are fully hermetically sealed to MIL-T-27A specifications.

Included in the new group are 500 milliwatt types designed for pushpull transistor to 600 ohm line operation, a chopper input transformer, transistor interstage transformer, and a line-to-line matching transformer.

Circle No. 222 on Subscriber Service Card.

SILICONE RESIN

Dow Corning Corp. has developed a silicone resin that is said to establish new performance standards for high-temperature protective coatings. Identified as Dow Corning 808 resin, it provides greater gloss retention after long exposure to high temperature than was previously possible.



Typical formulation pigmented with titanium dioxide and thinned with xylene, retains its original 84% gloss rating after 100 hrs. at 482°F. When subjected to 572°F for 400 hrs, or to 482°F for over 2,500 hrs., its gloss rating drops to 70%.

Circle No. 201 on Subscriber Service Card.

FABRIC SEALS

Fuel-resistant, fabric-covered and fabric-reinforced seals for —65°F to 400°F applications are being produced by The Connecticut Hard Rubber Co. using LS-53, Dow Corning's new Fluoro-silicone rubber.

The fabric-covered seals provide high tear and abrasion resistance. The LS-53 fluoro-silicone rubber remains resilient, resists swelling and destruction by aviation

fuel and synthetic oils, even at extreme temperatures.

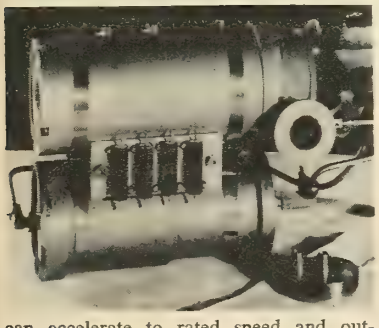
While the LS-53 fluoro-silicone rubber costs considerable more than ordinary silicone rubber, fabric-covered or fabric-reinforced seal constructions provide the most practical and economical use of the rubber.

The seals, custom made to meet customer design requirements, are already being produced for aircraft uses.

Circle No. 254 on Subscriber Service Card.

DIGITAL-ANALOG CONVERTER

A Multiverter for analog to digital and digital to analog conversion has been



developed by Packard-Bell Computer Corp. subsidiary Packard-Bell Electronics Corp. Conversions are said to be provided at better than 0.01% and at speeds in excess of 15,000 per sec. for analog to digital and 300,000 per sec. for digital to analog conversion.

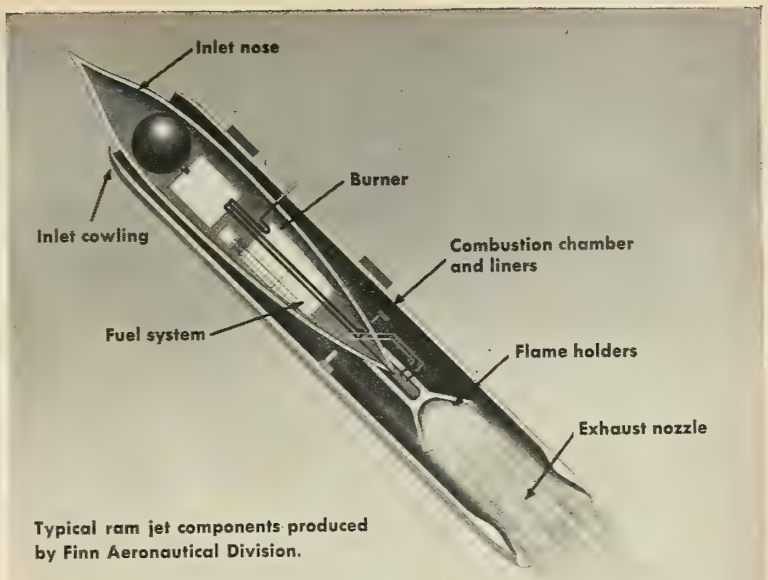
The unit is completely transistorized. It is claimed to be the first commercially available converter of its type that permits multiplication and division in the process of conversion.

Circle No. 230 on Subscriber Service Card.

POWER UNIT

General Electric Co. has produced a fully self-contained electric and hydraulic auxiliary power unit for missiles. It

can accelerate to rated speed and output within half a second.



The compact, turbine-drive unit consists of several modular components for versatility and flexibility of outputs and can supply electric power, hydraulic power, or both with ratings from 1.5 hp to 10 hp.

Circle No. 248 on Subscriber Service Card.

BALANCE UNIT

Ten 4-arm strain gauge bridge or resistive type pickups may be calibrated individually or simultaneously with a rack-mounted balance unit manufactured by Consolidated Avionics Corp.

Designed for large-scale instrumentation systems, Model 228 employs individual plug-in calibration resistors

Typical ram jet components produced by Finn Aeronautical Division.

We specialize in precision welded sheet metal components for missiles, jets and ram jets

We have the experience, the equipment, the men and the approvals to carry out your most complex experimental welding and fabrication of jet, ram jet and missile engine components.

Some of the superalloys we've worked and welded include N-155... A-286... the Nimonics... Inconel-X... Inconel-W... Hastelloy... Timken... and stainless steel. Two lines of cylinders, known as types AN and BN are being manufactured by the A. K. Allen Co. Both models feature a fork-type rear head for mounting, stainless steel rods, Nylined bearings, high tensile aluminum heads, honed brass or steel tubing treated for corrosion re-

sistance, and a choice of fixed or adjustable cushions for either end or both.

The bore sizes available are: ⅞", 1⅛", 1½", 2" 2½", 3" and 4". Type

LOAD! AIM! FIRE! automatically with VICKERS

hydraulic systems for missile handling and launching . . .

Name an important missile. Chances are that Vickers equipment or "know-how" played a part in its success. Every one of the missiles listed above, for example, depends on Vickers hydraulic units for some phase of surface handling, launching or testing.

Latest development is a completely integrated hydraulic system that brings true automation to missile handling. At the push of a button, missiles automatically flow from storage rack to final firing position.

There are important reasons for Vickers' success in heavy ordnance work. Long experience in this specialized field is one. Another is the fact that Vickers has the most comprehensive line of hydraulic equipment.

Hydraulics itself has unique advantages. On a recent project, a 100-horsepower transmission offered the ideal solution because of: —

High torque to inertia ratio — the pump end can be stroked from zero to maximum displacement in less than 30 milliseconds.

High power gain — a milliwatt input easily controls hundreds of horsepower.

Very narrow deadband — narrower than any other high horsepower drive.

High horsepower to weight ratio.

For one source convenience and one source responsibility, bring all your hydraulic problems to Vickers.

VICKERS INCORPORATED
DIVISION OF SPERRY RAND CORPORATION

Marine and Ordnance Department
Waterbury 20, Conn.

When tomorrow's rocket takes off for a destination in space, its propellant will undoubtedly be a high energy fuel-oxidant system . . . and the oxidant may well be ozone.

In the comparatively short period since the development by Welsbach of dependable tonnage ozonators, the applications of this versatile low-cost oxidant have broadened to include practically every industry. It is recognized for its specificity and purity in chemical synthesis reactions and has made possible increased yields of high quality products from cheap and abundant raw materials.

Specific uses for Welsbach ozone include the production of lubricants for high-speed motors and jets and the oxidation of corrosive chlorides in nitric acid recovery following atomic fuel extraction. Ozone also effectively removes phenol and cyanide from industrial wastes, and improves the oxidation characteristics of mineral oils.

These and numerous other uses indicate that the scope of applications for Welsbach ozone is unlimited. Through constant research, Welsbach continues to enlarge the field for ozone as an oxidant. With an unparalleled background in the design and construction of tonnage ozone plants, Welsbach offers you a long and varied experience in ozone application.

Call or write us today for help in solving your oxidation problem.

Write for this booklet on Welsbach Ozone Generation for Industrial Application. Please indicate company and title.

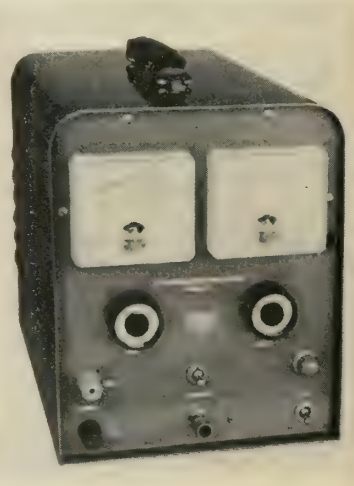
BN cylinders use cups for the piston head seals instead of the O-ring packing used in type AN. Double packing for the rod gland is also provided on the Type B. All cylinders are available as double acting or single acting spring return.

Circle No. 256 on Subscriber Service Card.

FILTER AND BLOWER

Packaged blowers are available in several sizes to utilize minimum of panel height in electronic rack from McLean Engineering Laboratories. Filter and blower section was designed to protrude



in the normally unused base section of the rack since blower is normally the bottom component of a relay rack. Models 2P408 and 2Q408 require 5¼2 on panel height but have performance of models requiring more height. Unit will dissipate a 1.5 kw heat load with an air temperature rise of 10°C.

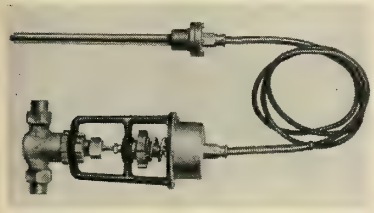
Circle No. 211 on Subscriber Service Card.

ULTRASONIC GENERATOR

Ultra-regulated low voltage dc power supply developed by Optimized Devices, Inc. utilizes an ultrasonic carrier sys-

tem to achieve optimum performance consistent with light weight, compactness, and efficiency. This supply, which can produce 0 to 7 v at up to 1.5 amperes, is said to be superior to batteries in almost all applications.

Typical uses are for strain gauges,



dc filaments, transistors, precision electroplating, bias supply, and for a precision laboratory reference even under load.

A number of feedback loops and corrective networks combine to keep the output voltage virtually independent of line and load fluctuations. Regulation is complete even down to O v. Negative voltage feedback is included for low drift, low noise, and low output impedance. Adjustable current feedback is included to reduce the output impedance to O ohms. The adjustment can also provide a negative resistance characteristic to compensate for lead length.

Circle No. 246 on Subscriber Service Card.

TEMPERATURE REGULATORS

Watts Regulator Co. has a new line of single seated temperature regulators for automatic flow regulation of liquids or

steam. These self-operating regulators are of two types—direct acting and reverse acting.

Direct acting regulators maintain the liquid temperature by controlling the heating source. They are available in sizes ½″ to 1½″ inclusive. Reverse acting regulators maintain the liquid temperature by controlling the cooling source. They are available in sizes ½″ to 1″.

Both types are easily adjustable for temperature control within 40°F operating range within 100°F and 240°F. They feature overheating protection and rugged bronze body construction with replaceable stainless steel seats.

New **VAN TRAILER** by Craig
houses all this equipment . . . with room to spare!

There's plenty of room inside the new insulated Craig Van Trailer LM-105! With its big 5,000 pound payload and roomy 575 cubic foot interior, this rugged van trailer can house 12 standard 6-foot racks, fully loaded with electronic equipment—and still allow ample space for operation and maintenance.

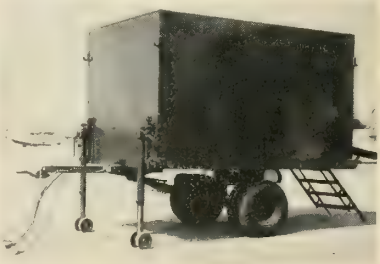
Whatever the load — a complete electronic system, test equipment, mobile maintenance shop, or you-name it—your equipment arrives quickly and safely in the LM-105. This versatile van trailer meets Government specifications for world-wide, all-weather use.

Quick facts about the LM-105:

WEIGHT: Approximately 4,000 pounds including dolly.

PAYLOAD: 5,000 pounds.

DIMENSIONS: (Inside) 140 inches long, 90 inches wide, 79 inches high.



INSULATION: overall shelter has U-Factor of 0.30.

FEATURES INCLUDE: aluminum-faced honeycomb panel construction; lighting system; power distribution box; cable entry ports; stairs; jacks for levelling; and a quickly detachable dolly with coil spring and torsion bar suspension, air-over-hydraulic brakes, and single beam towing tongue.

ACCESSORY EQUIPMENT AVAILABLE: includes air conditioner, heater, workbench, racks, cabinets, spare parts containers, etc.

AIR TRANSPORTABLE: By C-119 or larger cargo aircraft.

ELECTRONIC INSTALLATION: Craig provides complete layout and installation of equipment including wiring and component check-out.

Van Trailer LM-105, front view, with jacks in position.

For further information, write Craig today!

INDUSTRY SPOTLIGHT

By Norman L. Baker

Bell Aircraft Acquires Land for Research Center

BUFFALO—Bell Aircraft Corporation recently announced the acquisition of 350 acres of land near Pembroke on the New York State Thruway as a site for its new Lawrence D. Bell Research Center.

Two other significant developments were also revealed as part of Bell's program of consolidating its Niagara Frontier operations. They are:

1) Early completion of negotiations for a modern central warehouse on property purchased last year adjacent to the Wheatfield Plant.

2) Occupancy within 45 days of the new Electronic Data Processing Center now being finished at the Wheatfield Plant.

"With completion of the Research Center's first unit and occupancy of the new data Center, Bell Aircraft Corporation will own properties and equipment in the Niagara Frontier area valued at more than $34 million," President Leston Faneuf said.

"This does not include the new warehouse, which will be built by outside interests and leased back to Bell, nor the 12 government-owned or private properties now under lease to Bell," he continued.

"While we have been reducing our employment owing to changed Department of Defense requirements, we believe that construction of these new facilities, as well as other plans for the future, is concrete evidence of our corporate program to continue Bell Aircraft as a significant factor in the economic growth of the Niagara Frontier."

The site for the Research Center is located 1½ miles east of Pembroke on the Ontario section of the Thruway, near the junction of Routes 5 and 77 and was selected after several other sites had been investigated.

Initial expenditure for the research building will be $1 million. The first unit will be a hypersonic wind tunnel, capable of handling the highest speed ranges. This will be followed by a laboratory for heat studies and all services and facilities of the center will be available to other manufacturers.

Dr. Everett T. Welmers, formerly Bell's chief of dynamics, has been named director of the Research Center and is coordinating plans for the Center's design and construction, which will start this year.

A new $750,000 building will house the Electronic Data Processing Center, first occupancy to begin in August. The Data Center will handle all the computing in support of Bell's technical programs, including those of the Niagara Frontier Divisions, the Research Center and the Bell Helicopter Corporation in Fort Worth, Tex.

In addition to processing technical data, the facility will also maintain accounting records, provide manufacturing and financial records and a wide variety of other services and information for supervision and management. Eventually, it will also furnish similar data to Bell's wholly-owned subsidiaries.

The warehouse site is located north of the Wheatfield Plant on Walmore Rd. and adjoins Bell's railroad siding. The building will be approximately 250,000 square feet. Bell will occupy the facility on a lease-back arrangement. Construction is expected to be started within 60 days.

"The Data Center and the warehousing building are essential in our program of consolidation and cost savings," Faneuf explained.

"We have had computer operations in a number of departments and warehousing scattered in a number of locations throughout the Niagara Frontier. A centralized location for both functions will prove more efficient, more economical."

Aluminum Co. of America Develops New Impellers

Aluminum Company of America has developed "premium strength" high-speed aluminum impellers that have survived testing during which they were whirled at nearly three times the speed of sound.

The impellers, primarily intended for missile use, receive their high strength qualities through carefully controlled foundry practices and the fact that impurities are controlled to a new minimum, according to Alcoa officials. Iron content, for example is held to 0.2% in the improved alloys.

The alloy most used in the high-speed rotating parts is 355-T6—5% silicon, 1.3% copper, .5% magnesium, and the remainder aluminum and normal impurities. T6 designates solution heat treatment followed by artificial aging.

Alcoa has been spinning aluminum components for aircraft engine superchargers, propellers, jet engine turbines and torque converters since 1940, but the 2,000 mph speeds have not been common until recent development of the high-strength alloys.

During testing, parts are rotated in a "whirl pit" until they fly to pieces. Reassembled, the parts reveal valuable

Circle No. 64 on Subscriber Service Card.

information to test engineers.

"Non-destructive" testing is done by coating the part with a brittle, lacquer-like substance and whirling it at speeds just short of the destruction point. Cracks in the coating show high stress areas.

Some parts have been spun without rupturing at peripheral velocities of 3,000 ft./sec.

Among the applications of the high-strength alloys in missiles are important structural castings for Douglas

Impeller mounted on test arbor at Alcoa laboratory. Part will be spun until it flies to pieces in "whirl pit."

Aircraft Co. Alcoa's high-strength casting process and Alloy A356-T61 give them some of the highest properties ever cast, according to a company official. In one case maximum tensile and yield strengths are 47.1 and 36.9 psi, elongation is 9%.

Lockheed Builds Lab For Missile Antennas

Lockheed Aircraft Corp.'s Missile System Division is building a facility for the design and testing of advanced missile antennas and radar devices.

Electronics experts and the division's antenna propagation department will be housed in the 10,000-sq.-ft. building at Sunnyvale, Calif. The site is located about a mile from present buildings at the division to minimize interference and improve accuracy of measurement in the study of radiation and propagation phenomena of electromagnetic waves.

Electronics Specialties Sales up 50% in '57

Electronics Specialties Co. sales this year are about 50% ahead of a year ago, according to William H. Burgess, president. Shipments for April and May ran above $400,000 monthly and the backlog is over $3 million.

ROCKET POWER PROGRESS REPORT

Atomic Radiation for Rocket Testing

by Alfred Cohen

Assistant Project Engineer in the Instrumentation Section of the RMI Test Department, Mr. Cohen is investigating new concepts for acquiring, reducing and evaluating test data. After graduating in mechanical engineering from City College of New York, he worked as a civilian test engineer for the Navy. Mr. Cohen came to Reaction Motors in 1954 as a Test Department Instrumentation Engineer.

Although the rocket engine in theory is an extremely simple powerplant, its development is a highly critical art. Successful operation of an engine depends upon the solution of many unique problems and the accurate measurement of unusual variables. One of the problems we encountered at RMI was the measurement of the corrosive effects of a new high energy rocket propellant, a problem we solved through the use of atomic radiation.

In determining the corrosive effects of propellants, it is essential that the sensing element employed does not come into direct contact with the propellant being tested. The propellant would rapidly damage or destroy most measuring equipment. In addition, the tolerance of the tests does not permit additional contamination from other foreign bodies.

We approached the problem on the basis that the density variation of the propellant could be the measure of its degree of corrosion upon the component materials with which it had been in contact . . . and the denser the material being tested, the less radiation would pass through it. We decided, therefore, to use the penetrating power of radiation as the tool to measure density variation.

To conduct the tests, a radioactive source and a detector for radiation were located so that the propellant being measured lay in a container between the two. The radioactive source emits gamma rays which penetrate through the propellant and its container. That part of the radiation that gets through the propellant and its container strikes the detector.

The detector contains a filling gas which is forcibly ionized when bombarded by atomic radiation. The energy of ionization is converted directly into electrical energy. Thus, an increase in the density of the propellant reduces the radiation field intensity at the detector, and results in a decreased generated signal.

However, accurate measurement of this energy is difficult because the generated signal is very low (in the magnitude of 1×10^{-13} amperes). To overcome this, an instrumentation system was specially developed to transmit, amplify and record this data.

The signal is transmitted to the amplifier by a special shielded cable that eliminates the effects of noise and other disturbances. Data is recorded by a Null system of measurement, using a ten-inch strip chart recorder. The recorder is calibrated to give full deflection for a density change equivalent to one tenth of a pound per cubic foot.

As a result of the data acquired by this test program, the research scientists have been able to improve the propellants to a point where they are both safe and highy desirable for use as rocket fuels.

This project is typical of one of the ways in which RMI Test Department supports the applied research, development and production projects associated with advanced rocket powerplants. All projects pass through this department, from the evaluation of components and fuels to the static "hot testing" of the entire engine system for an aircraft or missile before delivery.

The Test Department is staffed by a team of specialists highly qualified in mechanics, electronics, chemistry, and instrumentation. This team is constantly working to provide the most accurate possible test results and also to develop new equipment and methods that will allow for even more accurate information in the future. And—because this team is constantly expanding—we are always anxious to talk with top-rated engineers and technicians who are interested in test work.

4986

If you desire one or more reprints of Mr. Cohen's article, or would like to receive further information about employment at RMI, write to our Information Services Coordinator. Reaction Motors, Inc., 16 Ford Road, Denville, N. J.

Power for Progress

THE BIRD
THAT'S ATTRACTED TO STRANGERS

Audubon never observed it—this new species that won't tolerate intruders in the sky, tracks them down, destroys them.

Raytheon has pioneered in the development of electronic missile guidance systems for more than a decade. A technical milestone was reached when the Navy's experimental Lark, equipped with a Raytheon guidance system, achieved history's first destruction of an aircraft by a guided missile.

Today Raytheon, alone among electronics companies, is prime contractor for two missiles of advanced design: the air-to-air Sparrow III for the Navy, the ground-to-air Hawk for the Army. Here, once again, Raytheon's "Excellence in Electronics" is contributing to the security of the nation.

Scope of the Marquardt Aircraft Co. facilities at Ogden, Utah, where it will produce the ramjet engines for the Boeing *Bomarc* missile for the Air Force, is illustrated by fact that the total investment may reach $30 million within five years. Cost of constructing and equipping the production plant on a 66-acre tract adjacent to the Ogden Municipal Airport—shared 50-50 by Marquardt and the Air Force—will come to $10 million.

The Air Force is footing the $13.5 million bill for the test facility on a 2100-acre site at Little Mountain. Marquardt hopes this test facility will be completed by 1959. Until then it will ship Ogden-produced engines to California to be tested at its Van Nuys facility. Marquardt employment in Ogden will reach 500 to 600 by the end of this year. Ultimately Utah employment is expected to total about 3000.

•

Instead of television, North American Aviation uses ejectable, recoverable, missile-borne film cameras for color motion picture coverage of the XSM-64 in Florida. NAA's Missile Development Division designed a six-camera system to provide a variety of engineering data and documentary coverage from "on board" for the Air Force. Two of these camera packages were devised to be ejected during flight and parachuted into the sea on completion of their photographic job. They are recovered through a radio signal transmitted by each floating unit and detectable by an airplane at a distance of about 35 miles. Direction also is indicated.

A "T-boat" receives directions from the airplane to guide it into the area where its own radio receiver can locate the units at a range of about 1½ miles. Location is further aided by use of a visible dye marker solution on the surface of the water.

•

Lockheed's Missile Systems Division is using a power brake—ordinarily used to bend heavy metal—to chop out tapered and twisted 10-inch aluminum spacers. They are achieving greater uniformity than by the hand method. Two dies are used is the process. The brake can be adjusted to produce spacers with a twist ranging from 17 to 22 degrees. The new process does in four hours what had previously taken 80 hours, and does it more precisely.

•

Apprenticeship program being started by Hughes Aircraft Co.'s Tucson plant this summer is aimed at turning out 32 trained machinists, 25 electronic technicians and 10 tool-and-die makers during first four years. Program is jointly administered by Hughes and the International Association of Machinists.

•

Delays in ground equipment caused postponement of the test firing of the *Atlas* . . . Researchers are showing more and more concern over the low level of support being given to basic research in comparison to the large amounts of money being poured into applied and developmental work . . . Convair Cove is the name given to the new 52-acre housing project for Convair technical personnel at Cocoa Beach, Fla.

"FEVER THERMOMETER"

for supersonic jets

In order to break sound barriers, jet engines must break some temperature barriers, too—which brings some real problems in material selection. Any thermostatic control in contact with the hot jet gases must withstand temperatures of 2000° without significant change in properties and characteristics.

Faced with this problem, one of the world's leading designers and manufacturers of aircraft components and systems has made Kennametal* a "Partner in Progress"—and has found an answer. For a vital part of the sensing element in a thermostat assembly, a small tube of Kentanium* is used. This material, one of a big family of unusual carbides developed by Kennametal, retains its responsiveness and reliability through the entire flaming range of operating temperatures.

Perhaps you have some new product in mind that is still on the drawing board for want of materials with the necessary properties to meet an unusual operating condition. If the need is for superior corrosion or erosion resistance, hardness, strength and stiffness, or resistance to elevated temperatures, the chances are that you can find the combination of properties you need in the Kennametal line. Just write, outlining your problem, to KENNAMETAL INC., Dept. MR, Latrobe, Pa.

*Kentanium and Kennametal are the trademarks of a series of hard carbide alloys of tungsten, tungsten-titanium and tantalum.

Honeywell's Variable Inlet Diffuser
Controls Keep the "Hustler" Hustling

ENGINEERS
SCIENTISTS

WORK ON ADVANCED PROJECTS LIKE THIS

As mach numbers advance, even fractional errors in inlet-air diffuser positioning reduce thrust tremendously.

Yet a fixed diffuser designed for optimum pressure at a given high mach number may be so inefficient at a lower mach number as to render it impossible for aircraft to reach design speed.

In the U.S.A.F.'s first supersonic bomber, Convair's B-58 Hustler, this problem was solved by Honeywell's variable inlet-air diffuser systems—the most accurate known. They are automatically controlled to the proper parameters to achieve maximum pressure recovery and mass air flow matched to engine requirements.

The Challenges to Come!

Variable inlet diffuser systems are just one of 114 research and development projects in which Honeywell Aero is engaged. These projects are in the basic areas of:

INERTIAL GUIDANCE • FLIGHT CONTROL SYSTEMS • LIQUID MEASUREMENT SYSTEMS • VERTICAL, RATE AND INTEGRATING GYROS • DIGITAL AND ANALOG COMPUTERS • JET ENGINE CONTROLS • AIR DATA COMPUTERS • BOMBING COMPUTERS TRANSISTOR AMPLIFIERS • INSTRUMENTATION

Each of these projects offers exceptional career opportunities for capable engineers and scientists.

And Honeywell's rapid growth assures you of early advancement. Engineering personnel at Honeywell Aero has tripled in the last 5 years, is still growing faster than the avionics industry average. Supervisory positions open quickly, are filled from within. The first-rate salary you start with at Honeywell is *just the start.*

Write today!

For more information concerning these opportunities, send your inquiry or résumé to: Bruce D. Wood, Technical Director, Dept. TA19E, Honeywell Aero, 1433 Stinson Boulevard, Minneapolis 13, Minn.

Honeywell
Aeronautical Division

Grand Central Makes Major Reorganization

Grand Central Rocket Co. has announced a major shifting in its project management organization. Willem Schaafsma, formerly director of engineering, is director of projects with a staff of five project managers. They are Angus Scott, D. H. Eccles, Rod Andrus, Wilbur Hartzell and Harold Bartel.

Scott is Schaafsma's assistant. Hartzell is senior engineer on the third stage of project *Vanguard.*

Republic to Study High-Temp Hydraulics

Republic Aviation Corp. has been awarded an Air Force contract for the study and design of a 1,000°F hydraulic system.

The contract includes mock-up of the system and associated components such as seals, pumps, material filters, electro-hydraulic valves, tube fittings, electrical wiring and test equipment. Republic also will study and develop high-temperature hydraulic fluids for this system.

ACF Forms Division For Advanced Products

ACF Industries, Inc., has formed a new Advanced Products Division which will specialize in pressed-metal items, special weldments, aircraft and missile components and other products. Division will contain personnel and facilities at ACF's St. Charles, Mo., and Milton, Pa.

Lockheed Gets X-7 Contract Extension

Lockheed Aircraft Corp. has received a $14.5 million Air Force contract for continuation of its X-7 ramjet engine test vehicle project. The new contract will extend the program into mid-1958.

The X-7 is used to check ramjets in supersonic runs at Holloman Air Development Center, N. Mex.

Westinghouse to Design, Build *Polaris* Systems

Westinghouse Electric Corp. will design and manufacture experimental seagoing handling and launching systems for Navy's *Polaris* ballistic missiles. Work will be done at the Sunnyvale, Calif., plant.

Program will involve a series of experimental systems leading ulti-

mately to a submarine launching for *Polaris*. Contract is with Bureau of Ordnance.

Richard N. Parkin, manager of the long-term missile launching and handling project at Sunnyvale and company coordinator, has recruited a staff of engineers and supporting technicians to work in a restricted area at the plant site.

Bristol Opens Three Branch Facilities

The Bristol Co. has recently opened two new branch factories and repair laboratories and relocated its Pittsburgh, Pa., district office.

Branches opened are at Houston and Los Angeles. The Pittsburgh office has moved to 2250 Noblestown Road and a new building housing sales and service staffs for industrial instruments for recording, controlling, and telemetering, electronic components, and pressure actuated aircraft devices.

Overtime Cut Reduces Ryan Payroll

Ryan Aeronautical Co. estimates payroll reduction resulting from the Department of Defense directive cutting out overtime will be about $120,000 a month.

The figure is based on an average four-week period of overtime work on the KC-135 and *Firebee* projects.

Sperry Rand Builds Florida Facility

Sperry Rand Corp. is building a $2 million facility at Clearwater, Fla., for development of advanced radar instrumentation. First building to go up will be a 75,000-sq.-ft. laboratory for Sperry's newly organized Electronics Division. Operations are scheduled to begin late this year.

Gyroscope Assembled Under Microscope

Microscope aids technicians at AC Spark Plug Division of General Motors assemble parts of a gyroscope for use in missiles. Work is done under plastic shields in special air-conditioned rooms to make certain gyro is free of dust.

Chance Vought Files Debenture Issue

Chance Vought Aircraft, Inc., has filed a Security and Exchange Commission registration statement covering proposed issue of $12.5 million of convertible subordinated debentures. This

DATA PROCESSING SPECIALISTS!

Get in now—at the beginning of the new era in missiles!

When you join Telecomputing's Engineering Services Division, you will be given full scope to allow you to grow . . . your talents will be used to the fullest . . . recognition and rewards will be yours as a matter of course.

Not only is Engineering Services a member of an integrated five-company missiles systems corporation which designs and manufactures its own data-processing equipment, but it is responsible for *most of* the data reduction of the integrated Holloman-White Sands range flight testing of all types of missiles including the newest developments in the field.

marks the first public financing of the firm since it became independent of United Aircraft in 1954.

Funds will be used to reduce bank loans incurred to finance increased inventories and accounts receivable. Debentures will be convertible into common stock through July 1, 1967. Harriman & Ripley & Co. heads the underwriting group.

Litton Sales up 90% For 1st Nine Months

Litton Industries realized sales of $20,372,000 for the first nine months of the current fiscal year, a 90% increase or the comparable period last year, according to Charles B. Thornton, president.

Profits of $1,154,236 for the period which ended April 30, were an 85% increase over last year. Earnings per share were $1.10 on the $1,-154,236 outstanding. Backlog April 30 was $44 million, a new high.

DFI Completes Test Program for *Redstone*

Designers for Industry, Inc., has completed four pieces of testing equipment for the *Redstone* rocket missile under sub-contract to the Chrysler Corp. Equipment tests guidance mechanism and other components of missile during production and just prior to launching, DFI officials said.

NAA Gets Subscontract For *Titan* Equipment

North American Aviation's Los Angeles Division has received a subcontract from The Martin Co. to build ground equipment for the *Titan* missile, Work will begin immediately on the transtainer units used to transport the big missile on the ground.

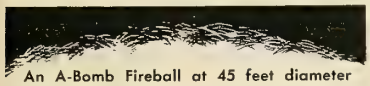
Oregon Firm Casting Titanium, Zirconium

Oregon Metallurgical Corp. is producing titanium and zirconium castings in a 100-lb. capacity consumable electrode furnace.

Since the metals in the liquid state react with every known element except

AN FITTINGS
Stainless, Aluminum, Brass, Steel. All sizes—immediate delivery from world's largest shelf stock. Buy direct from manufacturer. Lower prices—quicker service. Send for free wall charts showing complete line of AN Fittings.
COLLINS ENGINEERING CO.
9050 Washington Blvd., Culver City, Calif.

argon and helium, the mold itself must be contained in the melting furnace. Water cooled copper and graphite molds have been successfully used and castings of 125,000 psi tensile strength produced.



Castings will soon be available in pure titanium, zirconium or alloyed with aluminum, vanadium, tin, chromium, manganese, molybdenum and other alloys.

Coleman Increases Board Membership

Coleman Engineering Co. Board of Directors has been increased from seven to nine members. New seats are filled by E. A. Gardner, vice president and general manager of the company, and James Beattie, president of Photographic Products, Inc., Anaheim, Calif., a Coleman subsidiary.

ARDC Lets $81,000 Contract For Plan

Air Research and Development Command has awarded a contract to Porter, Urquhart, McCreary and O'Brien of Los Angeles to prepare a master plan for its missile training center at Camp Cooke, Calif.

An A-Bomb Fireball at 45 feet diameter is 300,000° centigrade. If you're a fireball in any of the fields listed below there are some hot opportunities for you at ASCOP. Contact our technical personnel manager for complete details.

ELECTRONIC ENGINEERS
Skilled In
Data Acquisition • Data Handling
RF Techniques • Circuit Design
Transistor Applications • Technical Writing

Openings as of July 1

WHICH OF THESE 18 CAREER POSITIONS at ARMA INTERESTS YOU MOST?

New long range projects assure not only challenging, high-level creative work, but security and job stability as well. Excellent starting salaries plus all the resort and cultural advantages of suburban Long Island living. Moving allowances arranged.

A partial listing follows. Information on many more positions may be obtained by contacting Robert Burchell at the address below.

MISSILE PROJECT ENGINEER
Coordinate project analysis, planning and controls including determination of project requirements and commitments in missile field.

ELECTRONIC SYSTEMS ENGINEER (Field Service)
Liaison with associate contractors and government agencies on inertial guidance system project. Must be thoroughly familiar with matters relating to digital and analog computers, power supplies, environmental conditions, housing and test facilities and test equipment.

FIELD EVALUATION ENGINEER
Perform overall planning functions for field evaluation of missile guidance systems. Direct activities in scheduling the field operations. Liaison with field test site agencies and formulating overall operating procedures at test site on missile project.

MECHANICAL DESIGN ENGINEER
Perform mechanical design of airborne instrumentation and transducers required for field evaluation of missile guidance systems. Responsible for packaging and mounting equipments.

FUNCTIONAL ENGINEERS—MISSILE SYSTEMS
Develop inertial guidance systems including gyro, accelerometers, integrators, servo systems and computers. Analyze functional problems arising during development and evaluation of said system.

OPERATIONAL EVALUATION ENGINEER
Perform engineering studies and analysis of techniques for evaluating performance of missile guidance systems and its components including gyros, accelerometers, digital computers.

PLATFORM ENGINEER
Conduct investigation of a theoretical nature relating to gyros or inertial platforms including design of closed loop control equipment pertaining to the above.

GYRO DEVELOPMENT ENGINEER
Develop precision gyro systems including mechanical problems such as lubrication, temperature controls, hydrostatics and vibration and electronic work on accelerometers, amplifiers, torquing circuits and electrical pickups.

OPERATIONAL ANALYSIS ENGINEER
Development work on evaluation of inertial guidance systems including in-plant and flight analysis of gyro systems. Development of measuring devices for precise determination of in-flight velocity, acceleration, altitude and position information.

RELIABILITY ENGINEER
Develop methods for evaluation of accuracy, reliability and operational suitability of missile guidance systems.

SYSTEMS EVALUATION (MISSILE GUIDANCE)
Perform functional engineering studies and design of inertial guidance systems, determine system and component requirements and performance, conduct system and component dynamic studies and simulation, perform error analysis.

PROJECT ENGINEER—PRODUCTION TEST EQUIPMENT
Administer and technically direct the program of design, development and manufacture of test equipment for production use in the manufacture, inspection, test and reliability control of highly complex electronic, electro-mechanical and gyroscopic equipment required for missile application.

GROUND EQUIPMENT ENGINEER
High degree of technical and administrative responsibility on complex projects involving the design and development of production test and field test equipment for gyroscopic systems and digital computers.

PROJECT ENGINEER—AIRBORNE EQUIPMENT
Guide and assist engineers in technical problems in field of electrical and electronic design, servo systems, missile guidance systems. Responsible for major product improvement program and test programs. Provide technical liaison with quality control. Heavy servo background desired.

ENVIRONMENTAL ENGINEER
To plan, conduct and report upon development studies of finishes, materials and processes, which will be incorporated into the design of electromechanical and electronic components and systems.

OPERATIONAL ANALYSIS ENGINEER
To plan, conduct and report upon environmental tests of electromechanical and electronic systems. Must be capable of redesigning components or systems to correct any deficiencies encountered during the evaluation program in the computer, servo systems and missile field.

QUALITY CONTROL ENGINEER
Require experience in gyroscopic trouble shooting. Design knowledge of stable elements and some background regarding reliability and failure association for complex guidance systems to be used in missile field. Must have complete knowledge of statistical methods.

GROUND EQUIPMENT ENGINEER
Plans and performs engineering studies, basic electrical and mechanical design, development and evaluation of production test and field test equipment where specific objectives and general requirements are known. Must be familiar with electromechanical instrumentation.

Clip the job (or jobs) you're interested in and mail, with your confidential resume. No reference contact without your permission. You'll receive a prompt reply, and your copy of "Your Engineering Career with Arma," full of detailed information about this company.

ARMA

PIEZOELECTRIC
ACCELEROMETERS
FOR MEASUREMENT OF
SHOCK • VIBRATION

	Acceleration Range	Frequency Range
400 SERIES — ACTUAL SIZE — Sensitivity 30 mv/g	0.03g to 40,000g	0.1 cps to 20 kc
500 SERIES — ACTUAL SIZE — Sensitivity 5 mv/g	0.2g to 40,000g	1 cps to 20 kc

These newly developed wide range accelerometers employ barium titanate in compression and have a natural frequency of 75 kc. They are capable of meeting the severest laboratory and field requirements for shock and vibration studies encountered today in missile and aircraft work. Immediate delivery.

industry briefs

BARNEY CONTROLS INC. will integrate marketing activities of all divisions and product lines into a new marketing department headed by Edward A. Johnson as vice president for marketing.

OLIN MATHIESON CHEMICAL CORP., Aluminum Division has opened its first Olin Aluminum office in the U. S. at Atlanta. Office will be used as sales headquarters for Southern states.

AMERICAN ELECTRONICS, INC., American Laboratories Division, has broken ground for a new environmental test laboratory at Fullerton, Calif. Completion is slated for August.

DARCO INDUSTRIES, INC., has acquired controlling interest in the Demo-Haines Tool Corp. Darco will produce 9½-lb. Demo electric hammer at El Segundo. Company is designer and manufacturer of aircraft and missiles parts and equipment.

BELOCK INSTRUMENT CORP. has broken ground for its Engineering Center at College Point, Queens, N. Y. R&D center will contain 30,000 sq. ft. for engineering facilities.

WALDALE RESEARCH CO., INC., has moved from Las Vegas to El Monte, Calif. Firm is manufacturing electric and high temperature strain measuring devices.

INDUCTION MOTORS CORP. reports consolidated net sales of $2,489,945 for 1956. Figure includes six months operations of the company's new PSP Engineering Division. Net income for year was $127,364 on 141,179 shares outstanding.

MARQUARDT AIRCRAFT CO., authorized a 2-for-1 stock split by payment of a 100% stock dividend July 1.

NORTH AMERICAN AVIATION'S Autonetics Division has set up an eastern Branch office in Washington, D. C. at Cafritz Bldg., 1625 I St. N.W. under Norman P. Hays, manager.

MARQUARDT AIRCRAFT CO. reports net earnings of $605,236 in 1956, an increase of 80% over 1955. Sales reached an all-time high of $23,110,441, up 104% over previous year. Backlog on February 24 stood at $55 million, including a number of USAF contracts for production of ramjet engines for Boeing *Bomarcs*.

ATLANTIC RESEARCH CORP. of Alexandria, Va. has acquired U.S. Flare Corp. & Associates of Pacoima and Saugus, Calif. and will operate latter under the same name as an affiliate. USF specializes in rocket ignition systems, missile tracking equipment, pyrotechnics and high-explosive ordnance items. Acquisition gives the combined organization a current annual volume exceeding $4 million and a staff of 325.

TRANSFER by North American Aviation of its missile test facility operations from Patrick AFB to Cape Canaveral Industries Area has been completed.

THE SIEGLER CORP., Electronics Division, has been awarded a rapid tax write-for missile systems facilities in the amount of $130,000 at 40% allowance.

SYLVANIA ELECTRIC PRODUCTS, INC. has started construction of a multi-million dollar, 100,000 sq. ft. R&D facility at Amherst, N. Y. for its Electronic Systems Division. Target for completion is February 1958.

METALS & CONTROLS CORP., will open a west coast design engineering facility this month. William Jones will head the Los Angeles laboratory and office staff as project engineer.

New control for jets ...and industry!

Precise control of every operating pressure is a must for the jet engines that power our modern military aircraft.

To make matters tough for the design engineer, this control must often be automatic or semi-automatic, function reliably under many diverse conditions. *And, last but not least, the pressure-sensing element must often be as linear as it's possible to make it.*

Engineers at the Hamilton Standard Division of United Aircraft selected Bristol's capsular pressure sensing elements for the fuel control systems soon to go into planes like the Navy F8U Crusader, above.

For Bristol has built up a backlog of 67 years experience in manufacturing pressure-sensing elements for use in our own Bristol instruments under the most diverse operating conditions.

We've found out how to build them to take punishment —for example, they'll take 200,000 flexings at 30 cpm with no more than 1% change in characteristics. And we believe the linearity of Bristol elements can't be equalled anywhere in standard units.

Because of expansion of our facilities, Bristol pressure-sensing elements are now available to industry. They come in a wide variety of stock characteristics between the extremes listed below. Ask us for Bulletin AV 2001 for complete data. The Bristol Company, 173 Bristol Road, Waterbury 20, Connecticut. 6.69

RANGE OF CHARACTERISTICS
(Stock Capsules)

Characteristic	Range Min.	Max.
Outer diameter (in.)	1 5/16	2 11/32
Effective area (square in.)	0.40	1.67
Travel (in./psi)	0.0004	0.015
Pressure span (psi)		
• Expansion	2	100
• Compression	2	100
Deviation from linearity (max %)	1/4	1
Hysteresis effect (max %)	1/4	1/4
Allowable overpressure (max % to maintain linearity)	20	20
Temperature range (normal)	—65 to 300F	—65 to 300F
Temperature for 2% travel change	550F	550F
Spring rate (p/in., ±10%)	24	1875

Use the attached prepaid reply cards. Circle numbers shown on reply card that correspond with numbers appearing beneath items cribed. If no circle number accompanies the article or advertise- nt, give page number (and advertiser's name) on line provided at om of the card.

Your requests for information will be forwarded promptly to the panies concerned.

NEW PRODUCT BRIEFS

UM. For most stringent applica- such as crystals of intermetalic unds, Gallium 99.999% plus pur- said to have most interesting nductive, photoconductive and scent properties. United Mineral mical Corp.
No. 280 on Subscriber Service Card.

GON NUT. Development of hexa- t of advanced design allows fab- n from stainless steel to meet emperature, non-magnetic, corro- sistance and lightweight proper- ubing Seal Cap, Inc.
No. 266 on Subscriber Service Card.

OFF VALVE. Weighs 6½ oz., has essure drop of 4 psi at 2.1 ppm Solenoid unit operated by 24 vdc, power supply at pressures from 00 psi. Marotta Valve Corp.
No. 267 on Subscriber Service Card.

MOCOUPLES. Measure tempera- at precise (±.003" or closer) in- ocations, employing technique of ding ribbon junctions in "weld ts" at selected depths on ¼" ed plugs of steel and aluminum. t Controls Corp.
No. 268 on Subscriber Service Card.

CABINET. Universal cabinet for nmental testing of all types. Suit- or temperatures from —120°F to and can be arranged for altitude and also variable humidity con- Hudson Bay Co., Division of Lab- nc.
No. 269 on Subscriber Service Card.

RDING OSCILLOGRAPH. Gives readout at exceptional speeds. up to 50 channels of informa- gives legible records dc to above cps—writes at speeds above ips, uses standard 102 type gal- eters. Midwestern Instruments.
No. 270 on Subscriber Service Card.

RECORDER. Designed to meet requirements. Has safety erase in- k, push-button operated, accom- tes reels up to 10½". American onics, Inc.
No. 271 on Subscriber Service Card.

ON RECTIFIERS. Designed and factured for the extremely rigid ements of MIL-E-1. Rectifiers range of 100 to 600 v peak in- and are of alloyed junction con- ion with all-welded hermetic seal. ral Instrument Corp., Automatic facturing Division.
No. 279 on Subscriber Service Card.

POLE-MOUNT CABINETS. Provide weatherized protection in exposed locations. Designed to house carrier communications equipment in remote locations, suited for any 19" panel mounted electrical equipment. Avialable in two sizes. Warren Manufacturing Co..
Circle No. 273 on Subscriber Service Card.

POWER AMPLIFIER. Has widespread application in airborne telemetering systems, available in 17 configurations. Within same package volume, connectors, filament voltage and cathode bias are varied to extend the use of amplifier over wide range. 4.95" x 37" x 2", weighs 16 oz. Rheem Electronics Division of Rheem Manufacturing Co.
Circle No. 274 on Subscriber Service Card.

AIR LINE FILTERS. Automatic-drain with simplified design of drain mechanism, more efficient liquid removal and wider pressure and temperature operating range. Filters operate at top efficiency at air line pressure as low as 5 psi. C. A. Norgren Co.
Circle No. 275 on Subscriber Service Card.

OSCILLATOR CIRCUITS. Covering pulse widths of .0, .2, .5, 1, 2 and 5 micro-seconds. Units designed for triggered operation, will accept high pulse repetition frequencies. Two separate outlets available—positive and reversible positive or negative. Units encapsulated in epoxy resin. CBC Electronics Co., Inc.
Circle No. 276 on Subscriber Service Card.

AVIATION BRUSHES. Quick-filming brush grades require no sea level "break-in" filming run. Just seat them properly and they are ready for immediate service at practically any altitude within the scope of modern equipment. Stackpole Carbon Co.
Circle No. 277 on Subscriber Service Card.

BRIDGE RECTIFIER STACKS. Compact 23 kw silicon single-phase bridge rectifiers, engineered for heavy power conversion in high ambient temperatures. Rated at 50 amps, rectified dc when convection cooled, and 120 amps rectified dc when forced air cooled at 1,000 lfm. Maximum input voltage per junction is 300 piv, or 210 v rms. International Rectifier, Corp.
Circle No. 278 on Subscriber Service Card.

GAUGE CART. Developed to house and transport Precisionaire air gauge and related tooling. Oversize casters make cart easy to roll, top provides supplementary bench space, can carry own air supply. Sheffield Corp.
Circle No. 272 on Subscriber Service Card.

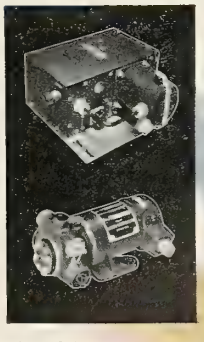
helping guide the NIKE

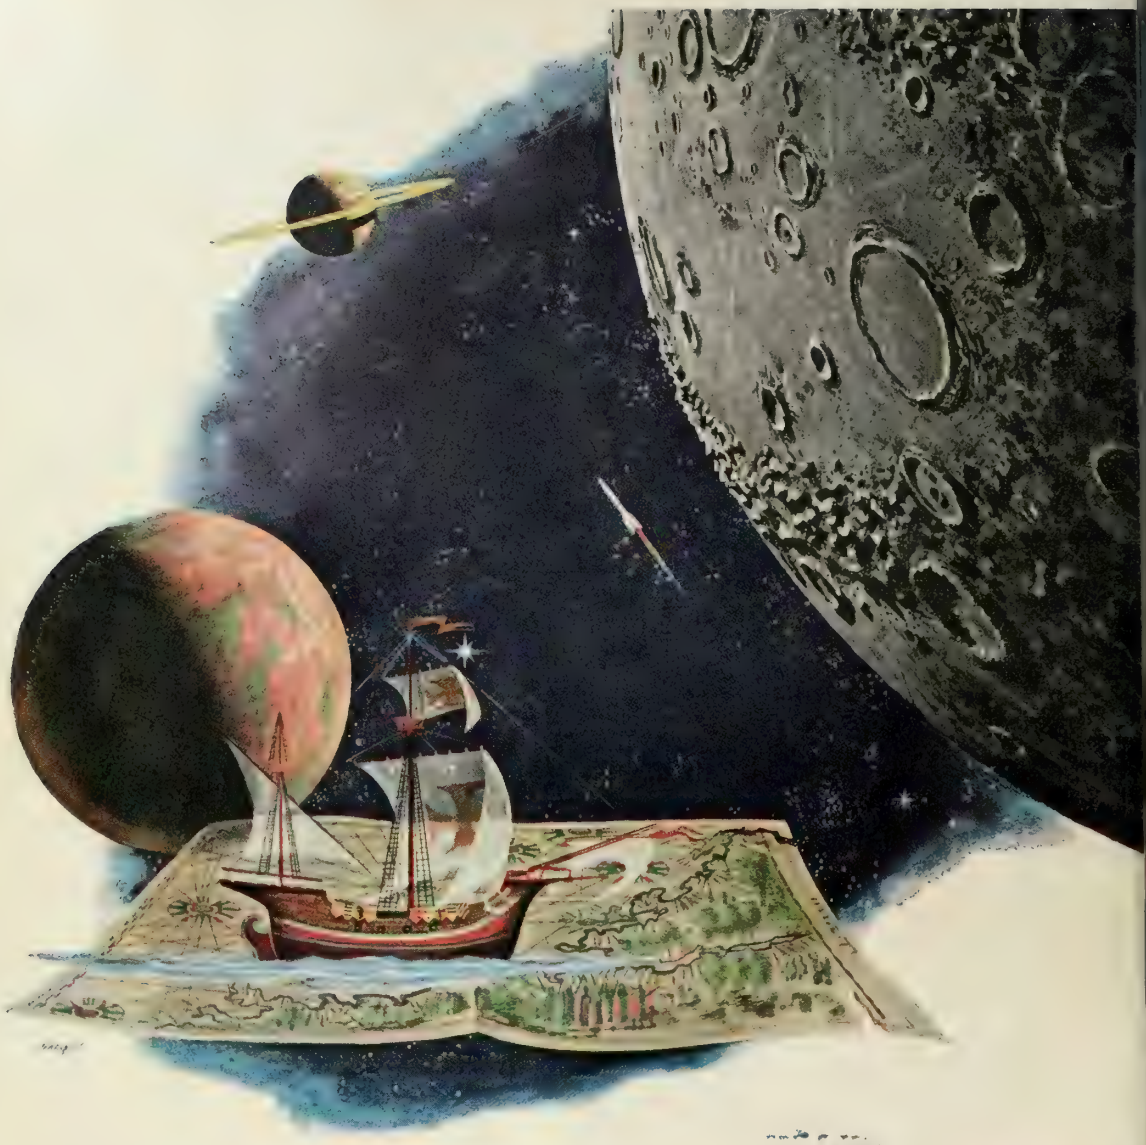


To intercept and destroy, Nike flies higher and faster than *any* aircraft. The electronic brain of the Nike outmanouvers the fastest fighter. To keep the Western Electric Control Unit thinking clearly, an Eastern Pressurization Unit and Aircraft Pumps control the operating pressures of the electronic systems.

Nike is the first missile to enter full combat-ready service. As others are developed to fly higher, faster, and deadlier, Eastern accepts the critical task of helping to break through the barrier of the unknown and untried. With *creative engineering* and the facilities to test and to manufacture new-idea equipment without delay, Eastern serves those who put the sting in national air defense.

When your design-application calls for the control of temperature or pressure in electronic installations, Eastern liquid-cooling units and pressurization equipment can help you meet government requirements.

Eastern hydraulic power units are extremely compact and provide extremely accurate control under severe operating conditions in servos and similar applications.



Eastern solicits inquiries involving your projects. We offer our creative engineering service for new designs, as well as an extensive line of existing units and adaptations.

Aviation Catalog 340, on request.

Eastern INDUSTRIES, INC.

Widening mankind's horizon by conquering

WIDE OPEN SPACES

Men of vision, making the unknown known, have widened man's horizon—advanced civilization. From the great *sixteenth century* exploration of the earth, its oceans, lands and peoples, came knowledge now in everyday use. Today at **CONVAIR**-*Astronautics*, scientists and engineers have already embarked on the greatest challenge of the *twentieth century*—man's conquest of the uncharted, unknown and infinite universe. Knowledge gained from solving the mysteries of space will bring mankind untold benefits.

CONVAIR

A DIVISION OF GENERAL DYNAMICS CORPORATION

CONVAIR-*Astronautics, is building a new facility at San Diego, California, which will be devoted to research, development, manufacturing and preliminary testing of the U.S. Air Force's Atlas Intercontinental Ballistic Missile, as well as other projects looking into the future of astronautics.*

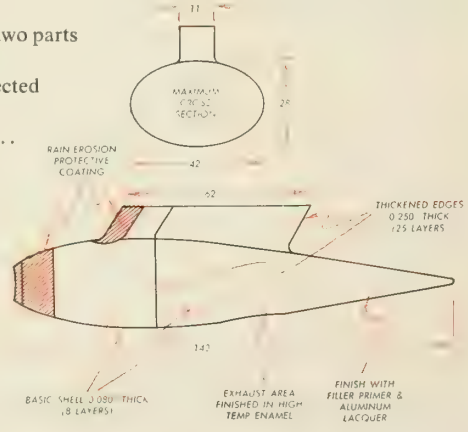
PROGRESS IN SOLID ROCKET PROPELLANTS

DOING JOBS EVERY DAY THAT METALS ALONE CAN'T DO

Convair C-131B Flying Electronic Test Bed with Two Pod-Mounted "Mars" APU's



BUILT TO STAND PUNISHMENT

Using tough, lightweight CONOLON 506

Solar Aircraft Company engineers were faced with a problem . . . how to aerodynamically enclose the "Mars" gas-turbine engine auxiliary electric-power generating units (APU's) to be mounted on Convair C-131B aircraft. The C-131B's so fitted were to be used for the in-flight testing of advanced airborne electronic equipment.

Housing the APU's required an aerodynamic pod built in two parts with multiple compound curvatures and drastically sharp bends. The materials problem presented was complex. The material selected had to withstand . . . temperatures of 400 F or even higher . . . contact with a special synthetic lube fluid for the turbine engine . . . high lead content exhaust fumes . . . ground handling abuses . . . aerodynamic wind loads . . . and severe abrasion because the pod was to be mounted only 12 inches above the runway.

The material that satisfied all these requirements? Conolon 506! Pods were assembled of this highly-formable Conolon 506 on low cost tooling and weighed less than 83 pounds each . . . another illustration of how Narmco's high performance products are *doing jobs every day that metals alone can't do.*

NARMCO

PIONEERING THROUGH RESEARCH

Write today for specific performance, design, and fabrication data on CONOLON 506. Narmco technical field representatives throughout the United States and Canada can assist in solving your structural design problems quickly, efficiently, economically.

NORTHROP NEW BUILDING NEAR FINISH

Full Occupancy In Late Summer

(HAWTHORNE, CALIF.) Partially occupied now, the new Northrop Engineering and Science Center at Hawthorne, latest step in a gigantic modernization and expansion program, is almost completed. Engineers and scientists of the Northrop Division of Northrop Aircraft, Inc., are ready for the big move into this beautiful, multi-million-dollar, glass and steel six-story building in late summer.

Architect's rendering of the Science Center is pictured above. Every convenience and facility will be provided for human well-being and comfort, in keeping with Northrop's theory that an engineer can do his work most efficiently in pleasant surroundings. Northrop has long maintained that an airplane or missile is only as good as the engineers who design it.

When fully completed, Northrop will have one of the most advanced test and experimental facilities in the entire aircraft industry. The Engineering and Science Center is the nucleus of this extensive development program. A four-unit Test Complex, which includes a Test Building, a high-performance, sub-sonic Wind Tunnel, a jet engine Test Cell, and an Environmental Test Laboratory, is now fully operative. Here, in these dramatic, modern buildings, Northrop engineers and scientists will continue with their never-ending study of airborne guidance, nuclear energy, the thermal barrier, aerodynamics, human engineering and other areas of missile and jet aircraft research.

MISSILE ENGINEERS

Many new positions are being created at Northrop Aircraft for missile engineers in a wide range of activity: control, guidance, servo, computers, recording, optical, reliability, electro-mechanical, telemetering and electronics. There's an interesting position for you, at your own experience level, with attractive remuneration and steady advancement, in one of the following groups:

GUIDANCE AND CONTROLS, encompassing research and development of advance automatic guidance and flight control systems for both missiles and piloted aircraft. Specific areas of development include: radio and radar systems, flight control systems, inertial guidance systems, instrument servo systems, digital computer and magnetic tape recording systems, airborne analogue computer systems, optical and mechanical systems, and systems test and analyzer equipment.

FLIGHT TEST ENGINEERING SECTION, which plans the missile test programs and establishes test data requirements in support of the programs. The data requirements are predicated on the test information required by the engineering analytical and design groups to develop and demonstrate the final missile design, and are the basis from which instrumentation requirements are formulated.

The analysis work performed consists of aerodynamic, missile systems, dynamics, flight control, propulsion and guidance evaluation. The Flight Test Engineering Section is also responsible for the field test program of the ground support equipment required for the missile.

FLIGHT TEST INSTRUMENTATION SECTION, which includes a Systems Engineering Group responsible for the system design concept; a Development Laboratory where electronic and electro-mechanical systems and components are developed; an Instrumentation Design Group for the detail design of test instrumentation components and systems; a Mechanic Laboratory where the instrumentation hardware is fabricated; and a Calibration and Test Group where the various instrumentation items and systems are calibrated and tested.

For 17 years Northrop Aircraft has pioneered in missile research and development. As a member of this forefront organization in this growing field, new opportunities for full expression of your initiative and ability will always be yours at Northrop.

If you qualify for any of these attractive positions, we invite you to contact the Manager of Engineering Industrial Relations, Northrop Aircraft, Inc., telephone ORegon 8-9111, Extension 1893, or write to: 1015 East Broadway, Department 4600-L, Hawthorne, California.

NOW all emergency flotation gear can be inflated at optimum speed with LYNDON'S new lightweight, self-contained jet air pump system.

This—another LYNDON design accomplishment—is the result of utilizing select materials, such as fiberglass shields, lightweight metals and an *EXCLUSIVE* air entrainment throat which reduces the volume of the stored air cylinder to a minimum in size and weight.

Actuation is by switch or manual pull cable. Deflation is made simple too—by providing a bleed valve in a readily accessible position.

LYNDON'S jet air pump system is unaffected by operating temperatures from −100° to + 275° F.

Write, phone or wire for more information relative to your application.

Avco makes things better for America...

Avco

Avco today

Avco's Lycoming powers new directions in flight

Now, in the lungs of Lycoming's advanced turbines developed under the sponsorship of the U. S. Army and U. S. Air Force, the gas turbine principle finds new usefulness for a variety of military and commercial aircraft applications. New vertical take-off and landing planes, helicopters, and other types of aircraft are capitalizing on the design advantages of Lycoming's low-weight, high-performance T53 and T55 turbines: compactness, versatility, ease of maintenance, ruggedness, long life, and low production and maintenance costs. Lycoming's growing turbine family offers government and industry a centralized source of turbine power in the 800 to 2000 hp range.

THIS IS AVCO

Avco today is a diversified organization whose products include aircraft power plants and structures, electronics for defense and industry, and specialized home and farm equipment. Avco's divisions and subsidiaries are:

Lycoming . . . American Kitchens . . . Crosley . . . New Idea and Ezee Flow . . . Research and Advanced Development Division . . . Crosley Broadcasting Corporation . . . Moffats, Ltd. (Canada)

Scientists interested in unusual opportunities for advancement can grow with Avco.

NEW

VICKERS®

Miniaturized

PISTON TYPE HYDRAULIC PUMPS

3000 psi . . . CONSTANT DISPLACEMENT

These new miniaturized hydraulic pumps were developed by Vickers for limited life applications such as missile and ram air turbine driven hydraulic systems . . . also for motorpump assemblies supplying emergency power on aircraft.

A distinctive feature is adaptability to manifolding and special mounting. This permits integration with the balance of a "packaged" hydraulic system to provide hydraulic power in the most compact and lightweight form yet devised. Some sizes are capable of delivering more than five horsepower per pound of weight.

Available in four size series, this miniaturized pump has the same basic characteristics as the standard Vickers piston type pump which has been establishing outstanding performance records on aircraft since 1940. Ask nearest Vickers Aircraft Application Engineer for further information.

Write for New Bulletin A-5216.

IN AVIATION, THE BEST OPPORTUNITIES ARE AT

TEMCO

MICROWAVE AND ANTENNA ENGINEERS

Experienced microwave engineers are required to perform research, development, and design on antennas, radomes, and microwave components. System engineers are needed for system development related to microwave receivers, Electronic Reconnaissance, Countermeasures, Radar and Transponder Systems. The work will be accomplished in the Radiation Laboratory in relation to prime missile and airframe contracts.

MISSILES AND AIRCRAFT ELECTRONICS ENGINEERS

Engineers with experience in transistor applications, pulse and video circuits, servomechanisms, general circuit design, guidance and radar system analysis, audio circuits, electro-optical transducers and optics are needed to perform system and detailed circuit design on guidance, radar, and television systems for guided missiles and high performance aircraft.

INSTRUMENTATION ENGINEERS

To plan, calibrate and evaluate instrumentation for flight test (including telemetry) and high temperature structural test. B. S. and/or M. S. degree and at least three years experience required.

SERVO ENGINEERS

To plan, conduct and report on developmental evaluation and qualifications tests of servo components and systems. Three years experience and applicable degree required.

For Precision Switching . . .

. . . try this Rugged and Reliable, featherweight squib-actuated switch

Designed for use in guided missile and special weapons circuits, the "OM-300 Series" Squib Switches are now available for general use wherever there is need for a compact, reliable device to open and/or close up to four electrical circuits simultaneously. The actuating squib is more sensitive than a delicate relay, yet switching action is faster and more positive than that of a massive solenoid switch.

The OM-300 Series includes all possible combinations of normally open and normally closed contacts in the four pole switch illustrated above. Switches of this series will solve many problems for designers of warhead fuzes, missile control systems, aircraft emergency systems, and missile telemetering systems.

- Size: ½" x ½" x 2⅛" (Terminals extend ⅛") (Non-delay)
  Weight: 280 grains (.64 oz.) (Non-delay)
  Number of Poles: 4, any combination of open and closed
  Current Capacity, Closed Pole: 25 amperes continuously
  200 amperes for 100 milliseconds
- Voltage, Standoff, Open Pole: 500 volts minimum
  Energy to Actuate Switch: With carbon bridge squib—500 ergs at 50 volts (Minimum values recommended)
  With wire bridge squib—5,000 ergs at 6 volts (Minimum values recommended)
- Switch Actuation Time*: Less than 5 milliseconds
  *Actuation Times as short as 0.1 millisecond and as long as 20 seconds will be available.

See "ATLAS" about your Explosive-Electromechanical Problems . . . .

Write today for additional data on this effective device.

Space Flight Without Red Tape

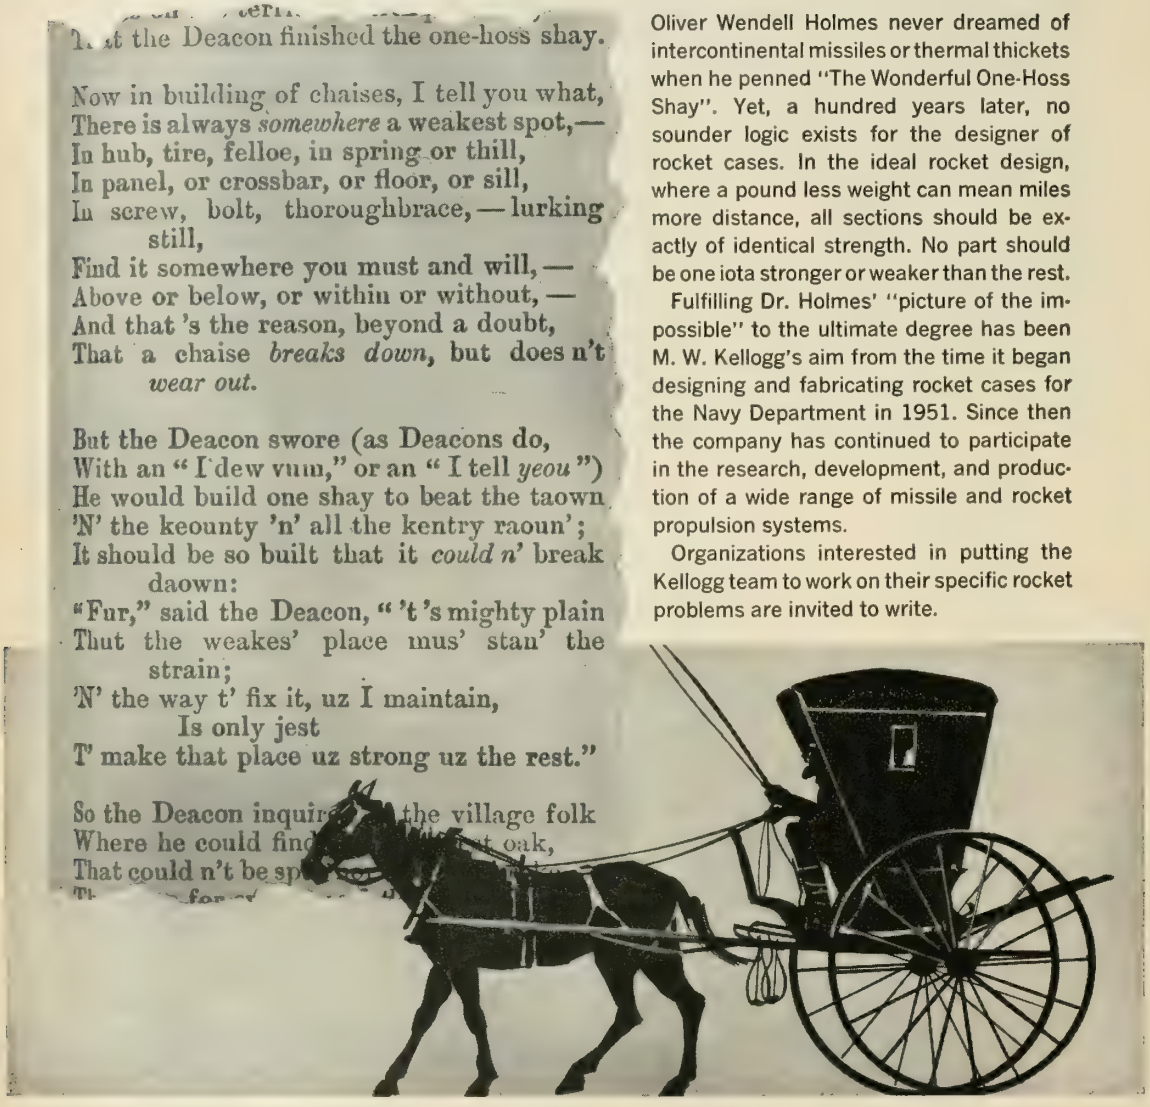
America's first space flight attempt is to be an Air Force venture using Army hardware and Navy methods. Industry and private scientists will put the vehicle together and instrument it. First of all, this is indicative of the fact that a unified group of our foremost research establishments must be coordinated into one central agency for successful pursuit of the astronautics challenge. Project *Far Side* is only the beginning. In scope, however, the project is more sophisticated than Project *Vanguard*. And in terms of politics it is far more interesting.

Space flight is not a glamorous little game that can be played by anyone just for glamor's sake. The Defense Department cannot arbitrarily choose any single individual or any single one of the services to supervise this country's overall aims to conquer the black yonder of space. The significance of such programs is too important in terms of expenditures and prestige. American industry certainly would not compliment the Defense Department if DOD should fail to make a thorough canvass of possible unification of efforts, talents and funds.

The Air Force Office of Scientific Research is to be commended for undertaking Project *Far Side*. Obviously, AFOSR recognizes the necessity for coordination and unification as essential ingredients for the project's fulfillment. Most important, however, is that the industry and military enthusiasts behind Project *Far Side* are aiming to penetrate outer space without political red tape—by picking the best methods and hardware available without caring which Service made them.

Project *Far Side* is simple. It is worthwhile. It is indicative of what a coordinated military and industrial effort can and will achieve with a minimum of expenditures and complexities. It uses off-the-shelf military hardware. No basic component for the rocket vehicle has to be redesigned, nor re-contracted. No expensive preflight tests are required. It does not cut into existing programs. When the first *Far Side* rocket is fired some time next month, the vehicle will be "live."

Far Side represents thousands of dollars rather than millions. Here we are working with simple, solid-propellant rockets instead of a combination of intricate liquid systems requiring five, six or more propellants or combinations of propellants.



Project *Far Side* makes the *Vanguard* project look like a hydra-headed monster. This also applies to such timid matters as releasing information to the public. The taxpayer, who is immensely intrigued by the idea that we are about to challenge outer space, does not understand why he cannot get the information on Project *Vanguard*.

But he does not know that every single word to the public must be cleared by all of these: the prime contractor; Naval Research Laboratory's Technical Information Office; the Chief of Naval Research; Office of the Chief of Naval Information; Office of Public Information of Department of Defense (including representatives of Army, Navy, Air Force and DOD); the Central Intelligence Agency; State Department; National Science Foundation; and the National Academy of Sciences (U.S. Committee for the IGY). This web of red tape on information is the big talk and the top sarcasm of the industry.

It is good that the Air Force is set on proving that we can spend less of the taxpayer's money and cut down the red tape on this country's first space flight project. And that there is no politics involved. It will pay. The public will expect the Air Force Office of Scientific Research to continue to pursue the space flight challenge in the future . . .

ERIK BERGAUST

Rocket Logic in Retrospect

t the Deacon finished the one-hoss shay.

Now in building of chaises, I tell you what,
There is always *somewhere* a weakest spot,—
In hub, tire, felloe, in spring or thill,
In panel, or crossbar, or floor, or sill,
In screw, bolt, thoroughbrace, — lurking still,
Find it somewhere you must and will, —
Above or below, or within or without, —
And that 's the reason, beyond a doubt,
That a chaise *breaks down*, but does n't *wear out*.

But the Deacon swore (as Deacons do,
With an " I dew vum," or an " I tell *yeou* ")
He would build one shay to beat the taown
'N' the keounty 'n' all the kentry raoun';
It should be so built that it *could n'* break daown:
"Fur," said the Deacon, " 't 's mighty plain
Thut the weakes' place mus' stan' the strain;
'N' the way t' fix it, uz I maintain,
Is only jest
T' make that place uz strong uz the rest."

So the Deacon inquir[illegible] the village folk
Where he could find[illegible] oak,
That could n't be sp[illegible]

Oliver Wendell Holmes never dreamed of intercontinental missiles or thermal thickets when he penned "The Wonderful One-Hoss Shay". Yet, a hundred years later, no sounder logic exists for the designer of rocket cases. In the ideal rocket design, where a pound less weight can mean miles more distance, all sections should be exactly of identical strength. No part should be one iota stronger or weaker than the rest.

Fulfilling Dr. Holmes' "picture of the impossible" to the ultimate degree has been M. W. Kellogg's aim from the time it began designing and fabricating rocket cases for the Navy Department in 1951. Since then the company has continued to participate in the research, development, and production of a wide range of missile and rocket propulsion systems.

Organizations interested in putting the Kellogg team to work on their specific rocket problems are invited to write.

IMPORTANT ENTRIES INTO AN IMPORTANT FIELD

HOUSTON FEARLESS PRODUCES: *Two New Precision Rocket Components...*

THE TURBINE WHEEL—A highly complex unit cut out from a single block of steel to precise dimensional requirements. Manufactured by Houston Fearless designed automatic tools. These turbine wheels are produced for various guided missile power plants.

THE SPIRAL BLADE IMPELLER—Intricately designed to meet the most rigid military specifications, the spiral blade impeller has a variety of applications within commercial installations. These pumping units for guided missiles are manufactured by Houston Fearless designed variable pitch generating machines.

Houston Fearless Also Manufactures These Highly Important Rocket Components:

HIGH PRESSURE PNEUMATIC REGULATORS—Designed for self-contained starter systems and for pneumatic ejector systems.

ROCKET ENGINE MOUNTING FRAMES—Tubular weldments are available for any size of power plant.

PRECISION DUCTING—Engineered for test installations or for power plants.

TRI-AXIAL NODAL POINT CAMERA MOUNT—Designed for ribbon frame cameras and used in conjunction with recording missile flight. Covers a full hemisphere.

For further information on any or all of these components, send in attached coupon today.

HOUSTON FEARLESS, Department
11801 W. Olympic Blvd., Los Angeles 64, Calif.

Please send me detailed information on:

- ☐ Turbine Wheel
- ☐ Spiral Blade Impeller
- ☐ High Pressure Regulators
- ☐ Tri-Axial Camera Mount
- ☐ Rocket Engine Mounting Frames
- ☐ Precision Ducting

Announcing —

*the AeroSWITCH**

A unique control device for monitoring pressures under extraordinarily severe conditions of temperature, vibration, and explosive pressure surge.

The AeroSWITCH monitors fluids between −297 and +5000°F, sustains pressure transients up to 8,000,000 psi/sec without damping, and withstands vibrations up to 2000 cps at 40 g.

Unequalled for ruggedness, reliability, and response, the AeroSWITCH has been proved in seven years of service on missiles and aircraft. It is one of the precision components designed and mass-produced by

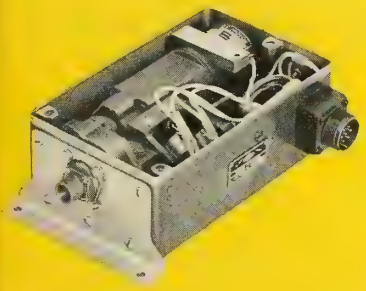
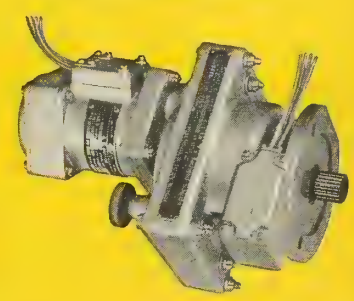
Meeting the stringent requirements of today's Missiles and Jet Aircraft

EEMCO ACTUATORS

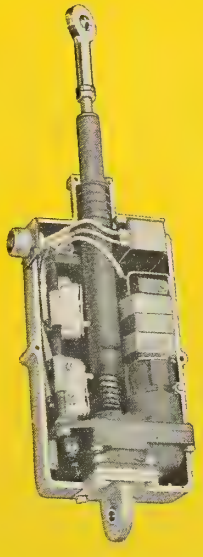
are now in use in the majority of our latest aerial weapons



Type: D-925 Rotary Actuator for Missile Fin. **Output:** 400 inch-pounds @ 64 RPM, 24 volts, 27 amps. **Duty Cycle:** 1 minute on, 10 minutes off; **Gear Reduction:** 135 to 1 in 2.25" length; **Weight:** 6.75 lbs. **Meets Mil. Specs.:** MIL-A-8064 for actuators, MIL-M-8609 for motors.



Type: D-818 Leading Edge Flap Actuator; **Weight:** 20.5 lbs. **Normal Operating Load:** 6,000 lbs.; **Maximum Operating Load:** 12,000 lbs. **Ultimate Static Load:** 24,000 lbs.; **Stroke:** 3.15"; **Rate of Travel:** .33" per second; **Amperes:** 3 amps at 480 cycles on 200 volts at the 6,000 lbs. load. **Meets Mil. Specs.:** MIL-A-8064 for actuators, MIL-M-7969A for motors.



EEMCO's low-weight, high-power linear and rotary actuators are designed and engineered to give consistent, top-efficiency performance under the most extreme environmental conditions. The widespread use of these rugged components can only mean that the entire aircraft industry recognizes their built-in accuracy and reliability. EEMCO, in turn, recognizes the importance of adhering to strict production schedules, and will continue to assure prompt delivery.

Type: D-892 Power Package; **Size:** 7⅛" x 4¾₆" x 2¾". **Output:** 28 volts D.C., 1390 RPM at take-off shaft, 18 inch-oz. torque. **Weight:** 3⅜ lbs.; Operative in ambient temperatures to 250° F. **Meets Military Specifications:** MIL-A-8064 for actuators, MIL-M-8609 for motors.

Type: D-868 Rotary Actuator; **Weight:** 9⅞ lbs. **Power:** 200 volt, 400 cycle, 3-phase motor. **Ambient Temperature Range:** —65°F. to +400°F.; **Shaft Torque Limit:** Adjustable. **Load:** 1,650 inch-lbs. maximum to approx. 2 RPM on 1.5 amps. **Meets Military Specifications:** MIL-E-7894 and MIL-A-8064.

Type: D-607 Transport Door Actuator; **Weight:** 4.5 lbs. **Stroke:** 6.25"; **Operating Load:** 450 lbs.; **Ultimate Static Load:** 7150 lbs. tension; **Speed of Stroke:** under 450 lb. load—0.3" per second. **Size of Power Section:** 2¼" x 4½" x 8⅝". **Meets Mil. Specs.:** MIL-A-8064 for actuators, MIL-M-8609 for motors.

Type: D-822 Trailing Edge Flap Rotary Actuator; **Weight:** 35 lbs. **Normal Operating Load:** 26,000 inch-lbs. **Maximum Operating Load:** 52,000 inch-lbs. **Ultimate Static Load:** 75,000 inch-lbs.; **Travel:** 45 degrees at .625 RPM; **Amperes:** 4 amps at 26,000 inch-lbs. at 480 cycles on 200 volts. **Frequency Range:** 380 to 420 cycles. **Meets Mil. Specs.:** MIL-A-8064 for actuators, MIL-M-7969A.

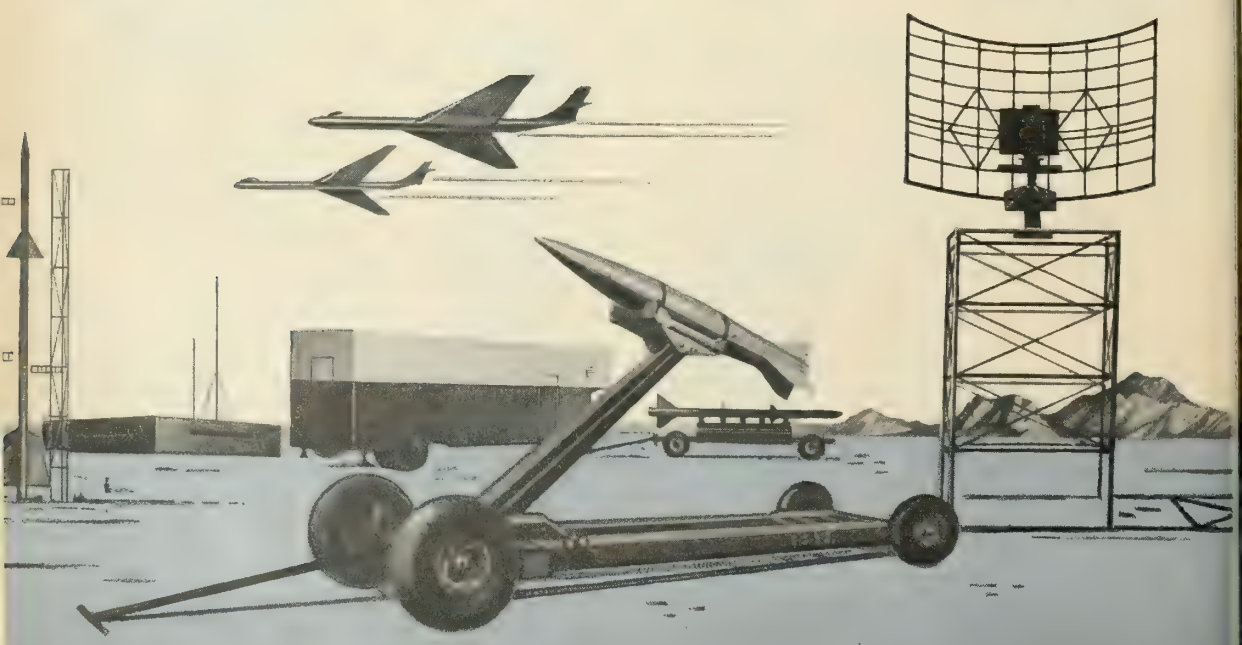
ERCO SUPPORT FOR ALL *Modern* WEAPONS

FROM SPECIALIZED EQUIPMENT TO COMPLETE SUPPORT SYSTEMS

From the smallest critical component to the trailerization of a complete missile tes and check-out system — this is the range of ERCO's abilities. Successful projects have been designed both from basic and creative concepts. ERCO engineers have broken with the past in creating products or systems which have fulfilled the national defense need.

A major activity of ERCO's weapon support program is weapon transportation. In this area, ERCO has designed and mass-produced equipment ranging from space saving, highly mobile shipboard dollies, trucks and skids, to versatile and highly specialized transports of larger and more sophisticated construction. Some of these transports carry weapons weighing 12 tons over the most rugged terrain.



Another important phase of ERCO's program is the design and manufacture of compl electronic and electro-mechanical test and check-out equipment as support for missile launching and flight guidance systems.

ERCO — a leading supplier of aircraft simulators, offers its extensive engineering an production facilities and experience to assist you in accelerating the training program vital to the effective introduction of new weapons systems.

If you have the weapon and need the complete support system or highly specialized engineering on separate equipments — write today Dept. MS, Riverdale, Md., for ERCO Weapon Support Brochure and learn how ERCO can help you.

fast fuel transfer

FOR MISSILES

Modern Missile technology has developed a vast number of new fuels, each requiring special handling and storage. The problem of safely and quickly transferring these fuels from the storage areas to the missiles is one which requires special equipment. Fast Fuel Transfer systems (FFT), developed by Flight Refueling, Inc., to increase range and payload of airplanes, lend themselves admirably to these new applications.

The experience which Flight Refueling, Inc., has gained in research, design and production of the FFT systems used on modern military aircraft is already being applied to solve the complex problems of split-second preparation of missiles for operational use with greatest safety.

If you have a perplexing missile or aircraft fuel transfer problem, Flight Refueling's engineers will be pleased to discuss it with you and suggest methods of applying the proved FFT principles.

ATTENTION ENGINEERS

Unusual career opportunities for engineering personnel are available in new projects for developing new fuel transfer systems. Write Engineering Manager for details.

IS YOUR JET ENGINE RPM MEASUREMENT ACCURATE AND SAFE?

TAKCAL®

READS JET ENGINE SPEED to GUARANTEED ACCURACY of 10 RPM in 10,000 RPM (±0.1%)

The inter-relation of RPM to efficiency and thrust in jet engines is fundamental. Proper adjustments for maximum thrust, maximum engine life and maximum safety of operation can be made only upon accuracy of instrumentation. The TAKCAL tests to guarantee that accuracy.

The new B & H TAKCAL incorporates a refinement of the frequency meter principle. It operates in the low (0 to 1000 cps) range, reading the frequency of the tachometer generator on a scale calibrated in percent RPM corresponding to the engine's RPM. It reads engine speed while the engine is running with a guaranteed accuracy of ±0.1% in the range of 0 to 110% RPM. Additionally, the TAKCAL circuit can be used to trouble-shoot and isolate errors in the aircraft tachometer system, with the circuit and tachometer paralleled to obtain simultaneous reading.

The TAKCAL's component parts are identical with those used in the J-Model JETCAL Analyzer. They are here assembled as a separate unit tester and for use with all earlier models of the JETCAL Tester.

The TAKCAL operates accurately in all ambient temperatures from –40°F. to 140°F. Low in cost for an instrument of such extreme accuracy, it is adaptable to application in many other fields.

For full information write or wire...

CHECKS TACHOMETER "SYSTEM" ACCURACY. ADAPTS TO ANY FREQUENCY PROBLEM!

Explosion-proof TAKCAL for special applications. Measures 200 to 7500 RPM, direct reading, with ±0.1% accuracy.

letters

Praise for m r First Special Issue

To the Editor:

Better and better! Suggestion: The coverage on missiles in the July issue was good. How about a future feature covering the available research missiles, such as Aerobee-Hi, Dan, X-17, etc. This should be as complete as possible, including size, weight, c.g., cost, etc. It would be even better if the page layout allowed margin for cutting out, for inclusion in notebooks.

Second Suggestion: A continued series on missile components; for example, solenoid valves, turbine pumps, telemetry packages, gyros, and so on. Basic theme: a system can be no better than its components.

R. P. Haviland
General Electric Co.
3198 Chestnut Street
Philadelphia 4, Pennsylvania

Thank you. A missile component issue is coming up.—Ed.

To the Editor:

Congratulations on the color spread entitled "To Probe Tomorrow" in last month's edition of MISSILES AND ROCKETS magazine. This functional use of color vividly portrays the research tools in GE's Aerosciences Laboratory.

Incidentally, I believe your readers should know that the Aerosciences Laboratory was initially established to provide research for the development of Air Force Ballistic Missiles under the direction of the Air Force Ballistic Missile Division, commanded by Major General B. A. Schriever, in Inglewood, Calif.

J. C. Hoffman

To the Editor:

Is it possible to obtain 25 copies of Dr. Wernher von Braun's article "Space Travel and Our Technological Revolution" as published in your First Annual Engineering Progress issue?

J. M. Schneider
The Cincinnati Shaper Co.
Hopple, Garrard, and Elam Sts.
Cincinnati 25, Ohio.

Reprints are in the mail.—Ed.

To the Editor:

Your July m/r guest editorial, "Science and Common Sense" could not have been more appropriate for your engineering progress issue. Also appropriately, it was written by the world's greatest exponent of the subject "science and common sense"—Dr. Theodore von Karman.

Checking m/r galley proofs: Dr. Theodore von Karman, right, with m/r's exec. editor.

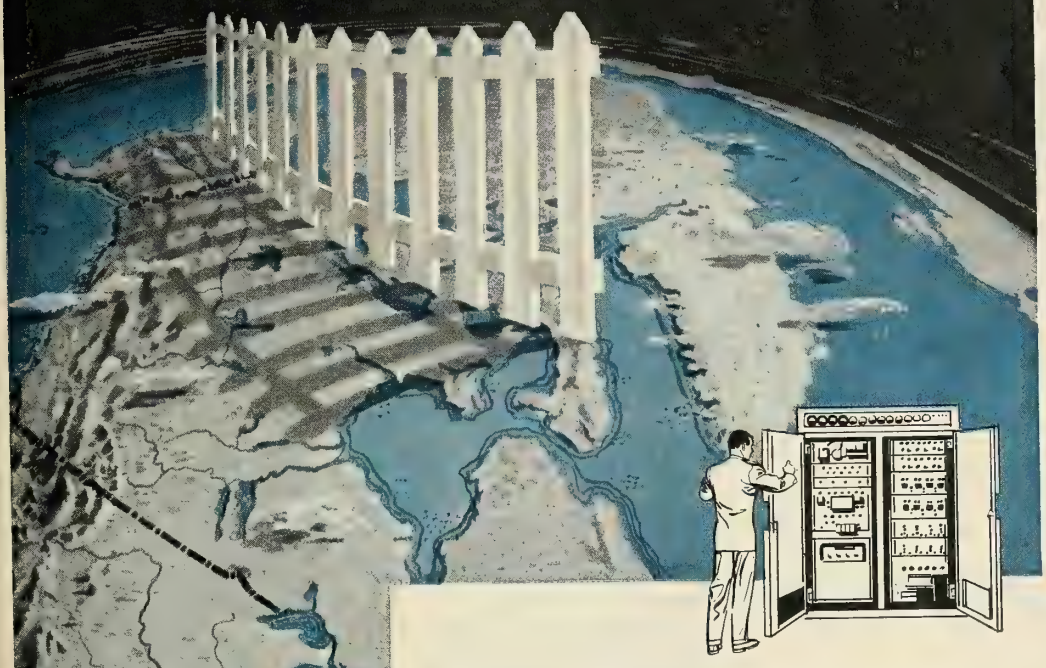
Only too often the work of the theoretical physicist is not implemented by the engineer due to the lack of technological intuition on the part of the business executive who authorizes and directs the activities of the engineer.

Those who profess to have management expertise have singularly failed to provide a program of technical enlightenment for the business executive. It is typical of Dr. von Karman that he would have the wisdom and common sense to discuss this problem.

I have the temerity to suggest that you run a series of articles on the subject.

Andrew G. Haley
Haley, Wollenberg & Kenehan
1735 DeSales Street N.W.
Washington 6, D.C.

To the Editor:



I am writing to tell you of my appreciation of m/r's recent coverage of Army missile activities and particularly to the activities of the Corps of Engineers in support of various missile programs.

MOTOROLA RADAR PICKETS IN THE "DEW-LINE" FENCE

Stretching 3,000 miles across the Arctic, special Motorola radar systems stand alert, ready to sound a warning at the first indication of an air attack over the polar cap.

The urgency of this distant early warning system called for a "crash" program for both development and production. Working in turn with the Lincoln Laboratories at M.I.T., Bell Telephone Laboratories, and the Western Electric Company, Inc., Motorola engineers came through with radar systems for the complete line within a 14-month period.

This is only one example of the military electronic equipment being developed and produced by Motorola for the varied military applications.

E. C. Itschner
Major General, U.S. Army
Chief of Engineers
Washington 25, D.C.

To the Editor:

Since m/r first appeared last year many of us here at Maxson have watched it carefully.

The July issue contains a terrific amount of information, particularly the First Annual Guided Missile Encyclopedia, beginning on page 123. This round up is the best job along these lines that we have yet seen. We wonder if reprints of this section are available. If so, we would appreciate having ten copies for distribution to our key personnel and engineering staff.

Keep up the good work.

S. H. Goldstein,
The W. L. Maxson Corp.,
Contracts Division
475 Tenth Ave.
New York 18, N. Y.

Thank you. The reprints are in the mail.—Ed.

To the Editor:

I was very pleasantly surprised to find in your July 1957 issue the "Guided Missile Encyclopedia."

I am an instructor in the U.S. Army Ordnance School and have spent countless hours trying to compile something similar for use in my instruction.

Is it possible to get about five reprints? We can sure use them.

Cutt R. Wild
Lt., Ord. Corps
U.S. Army Ord. Sch.
Box 195, APG, Md.

In the mail.—Ed.

To the Editor:

I have just returned from a trip to many of the Air Force Research and Development Command centers located throughout the nation. It was interesting to me to note the many copies of MISSILES AND ROCKETS that I saw on desks while visiting scientists at these various development centers. I think this is more than adequate proof of the job that m/r has done in covering this most important field . . .

Joseph C. Groth, Jr.
Executive Assistant to the President
Winzen Research Inc.
8401 Lyndale Avenue South
Minneapolis 20, Minn.

To the Editor:

I congratulate you on your excellent magazine. As a laboratory technician interested, but not yet connected with rocket propulsion in England, I find m/r of great interest and value. I also very much appreciate the advertising sections of this periodical, which presents in one issue more interesting information on missile components and developments than in several months of British aeronautical magazines.

This is, of course, due to the very high level of security on guided missiles in this country. Consequently British lay-

"Swifter than arrow from the Tartar's bow"

. . . wings the modern-day research rocket on its mercurial mission. Plunging through the heavy atmosphere at supersonic speeds, the Grand Central Rocket Co. ARROW is demonstrating amazing versatility and reliability in all phases of ultra-high speed research.

Grand Central provided the multiple ARROW rocket power-plant for the two-stage HTV (Hypersonic Test Vehicle) developed by Aerophysics Development Corporation for the United States Air Force. This vehicle approaches a speed of Mach 7 within two seconds, and is used for obtaining hypersonic data on rocket stability, aerodynamic heating, and air pressure distribution.

Grand Central Rocket Co.

Employment inquiries invited from qualified engineers and scientists. Confidential handling assured.

SOLID PROPELLANT POWER FOR • MISSILES • RESEARCH VEHICLES • BOOSTERS • SLEDS • SOUNDING ROCKETS

men have had to look to other quarters for their literature. Apart from the journal of the British Interplanetary Society very little information is available on current missile developments in this country. However, you have stepped in and very nicely filled the gap. I wish you every continued success.

Raymond A. Harraway
38 Waldeck Street
Reading, Berkshire,
England

Publication of Considerable Impact

To the Editor:

I would like to take this opportunity to compliment you on your publication. As an organization with eleven plants and laboratories actively engaged in missile work, we have followed the magazine from its very beginning. It is quite apparent that it is a publication of considerable impact . . . and might well have even more significant importance in the future . . .

The check list of special selections which you published this year is, I think, a very fine idea and one which should be repeated at intervals.

Alan Craigue
American Machine & Foundry Co.
1101 North Royal Street,
Alexandria, Va.

Pictures Suitable for Framing

To the Editor:

Minneapolis-Honeywell Regulator Company, Aeronautical Division, has recently completed construction of a new plant here in St. Petersburg. This plant has been set up for research and development on inertial guidance controls.

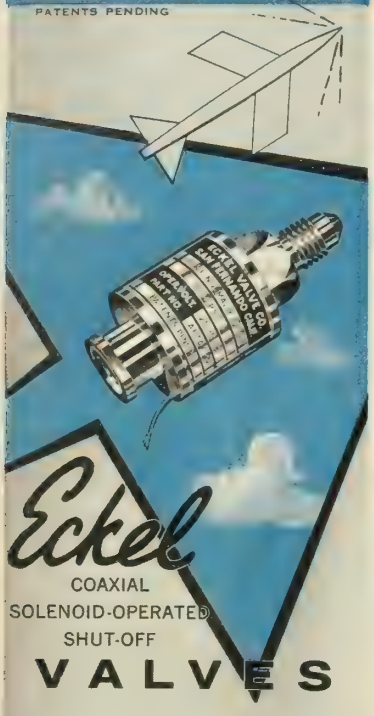
Because of our field of interest, we are most anxious to obtain pictures of missiles to place on the walls of various departments. We don't know where to go for pictures of this type and are wondering if perhaps you could help us. Any information as to possible sources would be most appreciated.

Mrs. Virginia Batchelor, Librarian
Minneapolis-Honeywell
Regulator Co.
St. Petersburg, Florida

Most companies in the missile business probably will be happy to provide you with glossy photos etc. Write to their Public Relations departments. Also, try General Astronautics Corp., P. O. Box 26, Oyster Bay, N. Y.—Ed.

Wants NACA Technical Note

To the Editor:



We are subscribers to your publication and we read in the June issue, page 100, an article regarding the new method of manufacturing by the NACA.

Could you be so kind and ask this Committee to send us their technical note No. 3827 referred to in the mentioned article; we do not know the address of the NACA.

on guard . . . the NIKE HERCULES

To guard our cities and other vital areas the Army's new Nike is more powerful than ever before.

Designated Nike Hercules, the ground-to-air missile maneuvers with pin-point accuracy at extremely high altitudes to intercept today's most advanced aircraft.

The range and other details of the Nike Hercules are secret. But to propel the lethal new Nike at supersonic speed to its target, Army Ordnance and Douglas Aircraft Co. chose an entirely new power plant for the missile proper— a solid propellant rocket system developed by Thiokol Chemical Corporation, one of the leaders in solid propellant engines.

Dr. Dorothy M. Simon, Technical Assistant to the President of Avco Research and Advanced Development Division, addresses a colloquium of the Advisory Group for Aeronautical Research and Development (NATO) in Cambridge, England.

The Science Center for Avco's Research and Advanced Development Division, as seen in the architects' scale model, is now under construction in Wilmington, Massachusetts, a suburb 15 miles northwest of Boston's cultural hub. Scheduled for completion in early 1958, this ultramodern laboratory will house the scientific and technical staffs of the division.

Avco's new research division is now offering unusual and exciting career opportunities for exceptionally qualified and forward-looking scientists and engineers in such fields as:

Science:

Aerodynamics · Electronics · Mathematics · Metallurgy
Physical Chemistry · Physics · Thermodynamics

Engineering:

Aeronautical · Applied Mechanics · Chemical · Electrical
Heat Transfer · Mechanical · Reliability · Flight Test

Write to Dr. R. W. Johnston, Scientific and Technical Relations, Avco Research and Advanced Development Division, 20 South Union Street, Lawrence, Massachusetts.

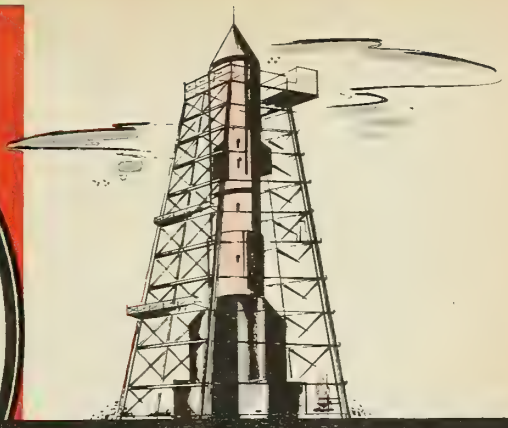
THE NEED TO KNOW

Man has long been motivated by the need to know—to
what lies beyond the oceans, the mountains and the sky; to
what elements make up the earth's crust and what forces c
the universe. Many questions have been answered, but a
knowledge increases and the boundaries of our space expand
questions are asked.

In the AVCO laboratories, exploratory work is under w
many fields of physics, physical chemistry, metallurgy, an
gineering. Basic research and development are continuing in
where we have already made contributions: high-speed ae
namics, ICBM re-entry problems, physics and chemistry
heat transfer, electronic applications to advanced radar
computing, and high-temperature materials.

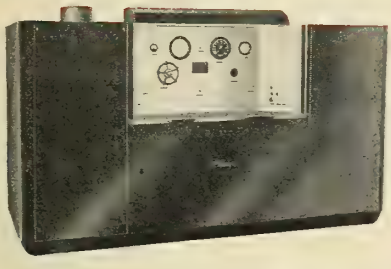
New ideas for future work are being discussed by the cr
scientists and engineers who are members of this division
scope of these new problems is so broad that the joint effo
those from many disciplines are required for their solution
future promises to be challenging.

A new research and development center, designed to g
proper physical environment and to provide the facilitie
equipment needed, is under construction. The center is lo
near large universities to make available educational opportu
and wide professional contacts.



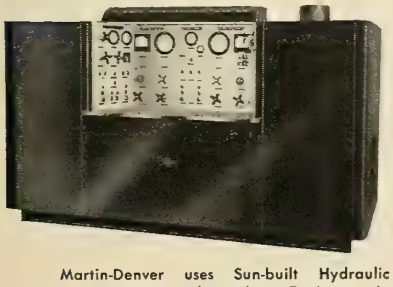
In the short period of our existence as a research and develo
division, much has been accomplished—problems have
solved and we have learned to work together. Now we are l
ning to broaden the scope of our work and to add our con
tions to the technical world, thereby strengthening the po
of America and helping to satisfy man's need to know.

Dorothy M. Simon



Dr. Dorothy M. Simon
Technical Assistant to the President

AVCO
RESEARCH & ADVANCED DEVELOPMENT



IN THE Final Countdown

Hydraulic Power Source and Auxiliary Testing Units produced for Martin-Denver play an important role in Martin's Missile Projects.

Martin-Denver uses Sun-built Hydraulic Power Source and Auxiliary Equipment in its important missile projects.

Up to the moment the "Fire" button is pressed, a missile is still reliant on the ground support that has prepared it for flight.

Countless tests, checks and rechecks have been made of its power, guidance and weapons systems. Electrically, electronically and hydraulically it is not yet self-sustaining—it must depend upon unfailing auxiliary equipment which fosters its flight.

Just as there is no margin for error in the performance of components once the missile is airborne, so, too, must the ground support equipment function with flawless perfection—the kind of perfection born only of engineering know-how—pride and quality of workmanship.

Sun's engineering and manufacturing capabilities are synonymous with critical precision—infallible performance. Whether it be ground support and auxiliary equipment to prepare a giant bomber, a super-sonic fighter or an intercontinental missile for its appointed mission—look to Sun for major assistance in development and swift "on schedule" production.

Simmonds
LIQUID LEVEL SENSING SYSTEMS keep Rockets ready for INSTANT LAUNCHING

Before the "FIRE" signal is given, a rocket or missile stands ready on the launching platform, frequently for a considerable time. Yet it must be ready to fire at any time, in spite of the evaporation of the highly volatile fuel and oxidizer liquids.

To keep fuel constantly up to capacity, Simmonds Liquid Level Sensing System senses when the fuel goes below a prescribed level. Automatically, the System then actuates a valve to add more fuel, shutting off when "full" level is reached. This process is continuous until the rocket is launched.

These Simmonds Systems have no moving parts—are shock, vibration and corrosion resistant—operate on low power consumption. They operate in any aircraft fuel, hydraulic fluid, jet engine oil and other liquids and liquified gases, meeting all MIL specs. Detailed literature on request.

missiles and rockets

Staff Scientist Dr. J. W. Muehlner (center) discusses an advanced PDM telemetering system for missile application with K. T. Larkin (left), Telecommunications Department manager, and J. R. Dawley, Telecommunications Systems Section head.

MISSILE SYSTEMS TELECOMMUNICATIONS

Weapon systems programs at Lockheed Missile Systems demand advances far exceeding the current state of telecommunications. Positions are open on the Palo Alto, Sunnyvale and Van Nuys staffs for scientists and engineers possessing a high level of ability and interest in:

TELEMETRY – Research in various areas of physics and electronics related to advanced telemetering projects; theoretical analysis of advanced FM, PDM, PCM System concepts; design integration of all phases of telemetry with weapon systems requirements; conception and development of original high-capacity and high-accuracy systems; development and package design of airborne telemetering equipment capable of operating under extreme environmental conditions, including transducers, subminiaturized subcarrier oscillators, crystal controlled FM transmitters, solid state commutators, PDM keyers, digital storage and conversion devices; development and prototype design of ground telemetry equipment to include devices such as high-efficiency decommutators, calibrators, digital encoders.

COMMUNICATIONS – Application of information theory concepts to challenging communication link problems; analysis and design of microwave communication link components to be utilized in most advanced weapon systems; development and test of television links for special projects.

Address the Research and Development Staff at Sunnyvale 7, or Van Nuys 29, California.

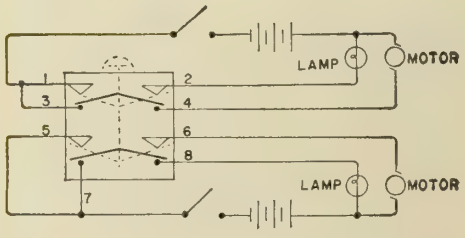
ROTARY MOTION SWITCH

10 AMPS @ 125/250 V a-c
10 AMPS @ 28 V d-c IND.
15 AMPS @ 28 V d-c RES.
Simultaneous DPDT without adjustment.

H10-7 SWITCH
(ACTUAL SIZE)

- A seal — not a packing — bonds shaft to case.
- Leakage rate LESS than 1 micron per cu. ft. per hour! Full rating up to 75,000 ft. altitude.
- No-slip splined shaft — adjustable or fixed actuating arm.
- Permits 120° rotary travel — a minimum of 50,000 cycles!
- Long overtravel eliminates need for fine adjustment; permits greater flexibility in linkage action.
- Tough, drawn-steel case. Rigid two-bolt mounting.



The many switching jobs done *best* by rotary-motion limit switches can now be done even better! Electro-Snap's new shaft seal gives you *positive* hermetic sealing, simplifies mounting, saves weight and space, and provides a full 50,000 cycle minimum life.

Elimination of external cranks, cams, links, and other gear to translate rotary to linear motion (as is often done to permit use of hermetically-sealed, lever type switches) reduces weight, space congestion, and the need for tedious adjustment. This simplicity gives you greater freedom in locating interlock and indicating switches on rotary mechanisms; allows positive linkage attachment.

Ice, altitude, rain, or corrosive atmospheres cannot effect this Electro-Snap switch sealed in a dry, inert gas. The steel case protects against shocks; prevents loss of the hermetic seal—also permits tight draw-up on mounting bolts without "springing" the case.

GET FULL ELECTRICAL AND MECHANICAL DATA IMMEDIATELY — WRITE FOR DATA SHEET H100-6

TYPICAL CIRCUIT

1-2—Remote Lamp indicates when arm is fully returned.

3-4—Motor driving linkage counter clockwise 120°.

5-6—Switch stopped motor at predetermined position.

7-8—Remote lamp indicates arm at full travel position.

WHY DOUGLAS ENGINEERS AND SCIENTISTS GO FURTHER...

At DOUGLAS, your career in missiles is backed by sixteen years of experience and an ever-expanding future

The finest talents and facilities in the industry have earned an outstanding position for Douglas in the national missile program.

You will become part of a team that has contributed more to the research, design, development and production of missiles than any other group in the nation.

You will work on projects that challenge the imagination... that stretch out far into the future ... that let you plan a secure and rewarding career with Douglas. Many of these projects have their roots in the mid-forties and are still growing.

Close coordination of missile and aircraft work provides an interchange of experience and knowledge among Douglas engineers and scientists. All plants are engaged in some phase of this missile program... making possible a broad choice of locations where you can work and establish living conditions suited to your taste.

For complete information, write:

E. C. KALIHER,
MISSILES ENGINEERING PERSONNEL MANAGER,
DOUGLAS AIRCRAFT COMPANY, BOX 620-R,
SANTA MONICA, CALIFORNIA

THIS IS NIKE HERCULES, a surface-to-air missile newly developed out of the original Nike system started in 1945 — a major project in the Douglas missile program.

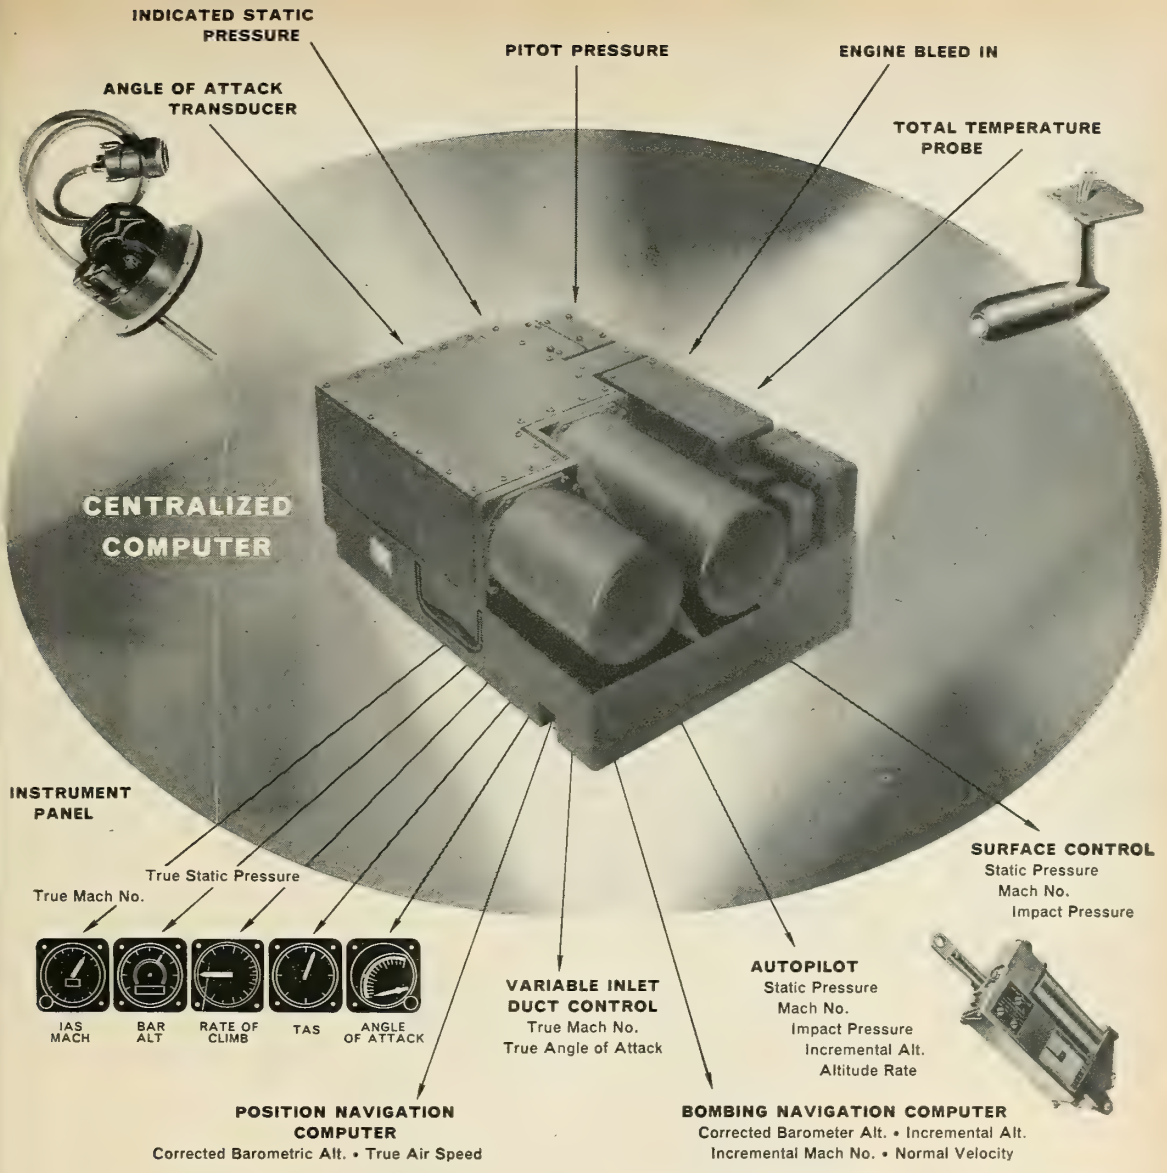
EDISON'S SIZE 8 GEARHEAD MOTOR

smallest diameter gearhead available, yet motor gives same output as a size 10 unit

OPERATING CHARACTERISTICS:

- Type of motor: Two phase
- No load speed (Min. R.P.M.): 6200
- Stalled torque (Min. in. oz.): 0.20
- Power input at stall (Nom. watts/phase): 1.7
- Speed at max. Power output (R.P.M.): 3950
- Torque at max. Power output (in. oz.): 1.2
- Theoretical acceleration at stall. 16,800 radians/sec.^{2}
- Time constant: 0.0416 sec.
- Duty: Continuous at stall

The Edison Instrument Division has met the challenge of greater miniaturization in servo motors for aircraft and missiles. The size 8 Gearhead Motor shown here is a typical example. This particular Edison unit can be supplied in any gear ratio within 2% and has the smallest diameter gearhead now available. Add to this salient feature the fact that this unit gives the same output as a size 10 motor and you have an ideal motor for such miniaturized projects as small panel mounting instrumentation and small computers for aircraft. Its light weight also makes this gearhead motor easily adaptable for missiles work.



The Edison Instrument Division now has this unit available in production quantities for fast delivery. Permanent tooling assures quality production of both short run and volume orders.

The Edison Instrument Division invites your inquiry. Write or wire for complete technical details. Mention your application.

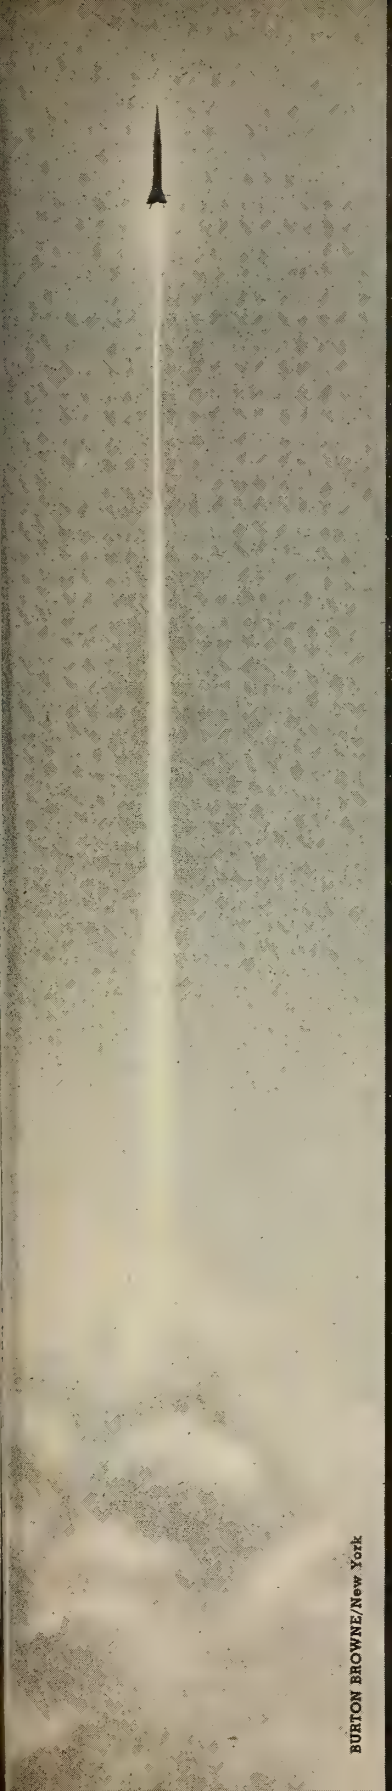
New punch for missile propellants

High heat of reaction, other characteristics point to magnesium for high-energy fuels

Magnesium, in its finely divided form, may well be suitable for new types of rocket fuels. It has long been known that a tremendous amount of chemical energy is locked within the metal. Upon further examination, finely divided magnesium has many significant characteristics that are important to the development of an efficient fuel:

High heat of reaction
Chemically reactive
High energy per unit volume
High theoretical flame temp.
Can be dispersed in various media
Products of combustion are: inert, relatively non-abrasive and present no toxicity problem
Inexhaustible raw material supply



Magnesium's heat of reaction, for example, compares to that of other fuel materials as follows: magnesium, 14,200 B.T.U. per lb. of oxygen required for combustion; aluminum, 13,370; lithium, 10,980; boron, 9,670 (all at 1800°K). This plus magnesium's high theoretical flame temperature indicates that magnesium is especially adaptable for short-range applications where high initial thrust is desirable.

In addition, magnesium can also be considered as an intermediate in the manufacture of other metallic and organometallic fuels.

For information about finely divided magnesium, contact your nearest Dow sales office or write THE DOW CHEMICAL COMPANY, Midland, Michigan, Department MA1438G

SPEED YOUR MISSILE

Precision Titanium, Stainless

FROM THE LEADING PRODUCER

Let the 4500 modern machine tools and the 10,000 experienced employees of the Jet Division go to work for you now. The tool and experience we have at work on components for jet engine assemblies can produce forgings and machined parts for missile air-frame and internal mechanisms.

Experience of the Jet Division includes the forming, welding, and machining of stainless steel, high-temperature alloys, and titanium. Complete heat-treating and testing facilities are available at the Jet Division. Development and engineering of any type of missile component can be handled by the Division's engineering and test sections.

Call today for a sales engineer who can discuss in confidence your missile requirements. He can show you how the Jet Division can augment your facilities to speed delivery, eliminate additional capital investment, break manpower bottlenecks.

WRITE FOR BOOKLET MR-257

Soviet IGY Rocket Program Revealed

Claim Satellites Soon; Moon Rockets by '60

In a formal statement by the Russians to U.S. IGY headquarters, the following outline of the Red program for launching of sounding rockets and satellites is revealed:

"The program of the USSR for the IGY includes studies of the atmosphere of the Earth by launching rockets and man-made satellites . . .

"As is known, vertical sounding of the atmosphere by means of rockets has been in progress in our country for a number of years.

"During the IGY we intend to continue and develop this work . . .

"In the Soviet Union, during the IGY the first launching of a man-made satellite with scientific purposes will be made.

"At present there are a considerable number of proposals by Soviet scientists about the employment of rockets and man-made satellites for this or that measurement. The proposals cover practically all the main questions of the physics of the upper layers of the atmosphere and other problems.

"This research is to consist mainly of the following:

"1) Structural Parameters of the atmosphere:

"Measurements will be taken of the pressure, temperature and density of the air at various altitudes and also of the structure of the atmosphere. Together with the measurements of the density taken by manometers, certain data will be obtained by observation of the orbit of the satellite . . .

"2) Optical Properties: The measurements will be made of the altitude and the brightness of the fluorescence of individual layers of the atmosphere, the scattering of light in the atmosphere . . . as well as the optical phenomena on the horizon.

"3) Ultra-violet and X-ray Radiation: The air envelope is a filter for the solar radiation. The atmosphere passes light beams with a wavelength not less than 0.29. The penetration of rockets and satellites into the upper layers of the atmosphere will enable us to study the ultra-violet and X-ray sections of the solar spectrum . . .

"4) Corpuscular Solar Radiation and Aurorae: Corpuscular emission of the sun calls forth sporadic violent variations of the Earth's magnetic field and disturbances in ionosphere . . .

"Solar corpuscules evince several other phenomena in the upper layers of the atmosphere, for instance aurorae . . . It is intended to measure the intensity of the solar corpuscular radiation, to determine the nature of the corpuscules, the velocity of their penetration into the atmosphere, both at calm and during big active processes on the Sun.

"5) Cosmic rays: It is known that the primary cosmic radiation, in the main, consists of hydrogen nuclei (protons), helium (particles) and, in much smaller number, of heavier nuclei (carbon, nitrogen, oxygen, etc.). One of the properties of the primary cosmic radiation is the similarity between the curve of the average distribution of the elements in the cosmos and the curve of the distribution of the shares of the primary component of cosmic radiation. Such elements as lithium, beryllium, boron, are rare in nature and the question regarding the number of their nuclei in the primary cosmic radiation has not been studied by experiment . . .

"Classed with the same range of questions should be the study of the variations of cosmic ray intensity at various altitudes and in different geographical regions.

"6) Ionospheric Physics: One of the problems regarding the structure of ionospheric layers is the determination of concentration of ions. It has been established by experiment that the co centration varies with altitude. In t connection, of great interest are t data on the ionization of the atm phere along the orbit of the satellite, along the trajectory of the rocket.

"The study of the radiowave p sage through the ionospheric layers w in a great measure improve our knov edge of the electronic density, and a regarding the degree of radiowave fa ing. As to other ionospheric measu ments there will be mass-spectromet measurements of the ionic content the ionosphere with a view to the c termination of its structure . . .

"7) Magnetic Fields: The short p riodic variations of the magnetic fie of the Earth are at present associat with the systems of electrical curre flowing in the upper layers of the mosphere. Modern data says that rin of such currents are located in Auro polar zones (in northern and southe latitudes) and around the equator.

The proof of the existence of the currents, their nature and the causes their origin are an important task scientific measurements to be made the satellite . . .

"8) Micrometeors and Meteorit The problem of micro-meteorites is great scientific and practical impo tance. On the one hand, the presen of micro-meteorites in the upper atm phere predetermines a range of phy cal processes influencing the state the atmosphere. On the other han micro-meteorites and meteors prese certain danger for the satellite. Calcu tions show that even small partic with a velocity of 50-70 km per seco can break through the casing of t satellite. Therefore, it is important know the concentration in space a the energy of micro-meteorites . . . solve this task instruments recordi the impacts (impact detectors) of m

teorites will be installed in the rockets and the satellites.

"9) Physical and Chemical Processes in the Upper Atmosphere: It is intended to launch different chemical reagents with the rockets into the upper atmosphere and to study the processes originating during their interaction with the surrounding medium.

"The entire geophysical equipment designed for the investigation of the upper atmosphere is housed in various containers. Some of the containers make up the vanguard part of a rocket with the instruments which is detached from the rocket following a certain time after termination of the engine operation. These Containers reach the altitudes up to 200 km. The containers are equipped with radio telemetry or instruments with immediate photographic recording. In the latter case the containers are saved . . .

The vertical firings of the rockets with a purpose of studying the upper layers of the atmosphere will be conducted in three zones located approximately along the meridian 50°-60° E.

First zone—the Arctic, the Franz Joseph Land, 80° N.

Second zone—middle latitudes of the USSR, 50-60° N.

Third zone—the Antarctic, mainly in the area of Mirny, 50-60° S.

The launching of the satellites will be made from the USSR at a small angle to the meridian. The satellite will revolve around the Earth and will be consequently observed in all the areas of the Earth except the central areas of the Arctic and the Antarctic.

Rocket Distribution by Zones and Years

First zone—1958—25 firings.

Second zone—1957—30 firings, 1958—40 firings.

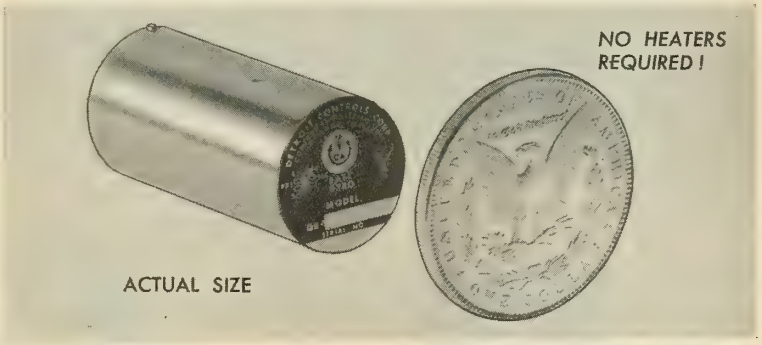
Third zone—1957-58—30 firings.

"At every firing of a rocket or the launching of a satellite a definite volume of the upper atmosphere investigations is being covered. When the rockets take up the containers of the first type, the study if made of the structural parameters of the atmosphere and of its optical properties, of the ultraviolet and x-ray parts of the solar spectrum, of the ionospheric phenomena and micro-meteorites.

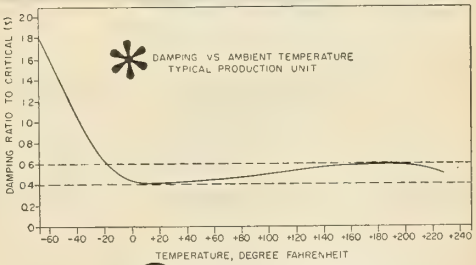
"When containers of the other type are taken up with the rockets, the range of problems studied includes the corpuscular solar radiation, aurorae and also the physical and chemical processes in the upper layers of the atmosphere. When launching the man-made satellites the programme includes geophysical, physical and astro-physical experiments in various combinations, and also other investigations such as the observation of the relativity theory effect, the study of the shape of the Earth.

"The firing of the rockets and the satellites will be conducted approximately evenly throughout the International Geophysical Year mainly on World Days and on occasions of active solar processes, Special World Days."

The official Soviet schedule calls for the first research rocket activity around the moon by the early 1960s.



This is announced by Yu. Khlebtsevich, chairman of the Soviet Technical Committee on Radio-Television Guidance of Rockets. These moon rockets will carry no humans, only radio and TV installations to report data back to the Earth.



The first unmanned rocket to the moon will be a small tank containing a laboratory — "a tankette-laboratory," Khlebtsevich calls it. This can be sent on its flight with no more than 250 tons of fuel.

"Moving upon the moon's surface," explains the Soviet scientist, "the tankette will incessantly take films and relay them to the Earth as television.

The SUBMINIATURE PRECISION RATE GYRO

With Constant Damping Over A Wide Temperature Range *

Check these unusual, high standard specifications

1. Constant damping (0.5 ±0.1 critical from −20° F to +220° F)
2. Subminiature size (0.937" dia. x 2.0" long)
3. Outstanding reliability (exceeds requirements of MIL-E-5272A Specs)
4. High resolution
5. Extremely high natural frequencies (up to 43 cps for 1 radian/sec; lower if desired)
6. Variety of motor characteristics available (3φ, 2φ, or split 1φ; 26V or 6.3V; 400 cps)
7. Wide variety of sensing ranges (from 0.5 radians/sec to 20 radians/sec, full scale)
8. Light weight; 3.7 oz.

AF Reveals XQ-4 Supersonic Target Drone

The turbojet XQ-4 target drone, partly released from security wraps, marks an outstanding advance in the development of high speed targets. Developed by Radioplane Co., a subsidiary of Northrop Aircraft, Inc., the XQ-4 will provide a more reliable evaluation of present air defense systems.

Resembling a scaled-down *Snark*, the drone will travel at supersonic velocities above 60,000 ft. It has both ground and air launch capabilities and is recoverable by three-stage parachute over land or water. XQ-4 is approximately 35 ft. in length and 2 ft. in diameter. Payload volume is sufficient to accommodate special tracking, scoring and photographic or television reconnaissance installations.

Several highly successful flight tests have been achieved at Holloman Air Force Base, N. M. All tests were conditioned by the Radioplane Co.

USAF XQ-4 supersonic target drone shown mounted on the wing of a B-50 launch aircraft. Except for short thin wings, it bears a remarkable resemblance to the SNARK.

RATO Costs Reduced H_2O_2 Still Expensive

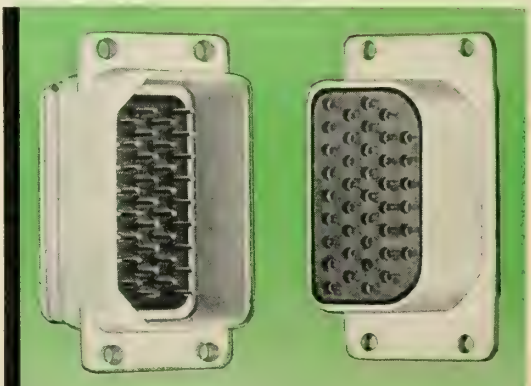
As reflected in a recent purchase order by the Navy Bureau of Ordnance, solid propellant RATO costs have taken a welcome drop. In the order Aerojet will deliver 22,630 units (15KS-1000) plus some spare igniters for about $155 a piece. Thus, hardware plus propellant cost for this unit is about $1.07 lb.

On the other hand, hydrogen peroxide is still an expensive item. Redstone Arsenal purchased 52,500 lbs. (half 90% CP-rest, 76%) for $29,859. This represents an average of $.57 .lb or about $.80 for the 90% material.

Martin Orlando Plant Nears Completion

Martin Company's Orlando plant, covering a 7000 acre tract and containing 500,000 square feet in four buildings, takes shape southwest of the city. The plant, under construction since April 2, will produce small weapons, guided missiles and electronics components. Scheduled for completion late this year, the facility will turn out *Lacrosse*, *Bullpup* and the Missile Master system.

ANOTHER Bendix ACHIEVEMENT



A resilient insert rack and panel connector

Here is the new and improved Bendix Type SR rack and panel electrical connector with outstanding resistance to vibration. The low engagement force of this connector gives it a decided advantage over existing connectors of this type.

Pressurization is easily accomplished. The resilient inserts press firmly against the shell wall holding the contacts in exact position. Insert patterns are available to mate with existing equipment in the field.

Adding to the efficiency of this rack and panel connector is the performance-proven Bendix "clip-type" closed entry socket.

Here, indeed, is another outstanding Bendix product that should be your first choice in rack and panel connectors.

OUTSTANDING FEATURES

Resilient Insert • Solid Shell Construction • Low Engagement Forces • Closed Entry Sockets • Positive Contact Alignment Contacts — heavily gold plated • Cadmium Plate—clear irridite finish • Temperature range −67° to +250°F. • Easily Pressurized to Latest MIL Specifications.

Nickerson Assigned to Panama Canal Zone

Col. John C. Nickerson, Jr., former technical coordinator at Army Ballistic Missile Agency, Huntsville, Ala., has been transferred to the Panama Canal Zone where he will have access to nothing more classified than "confidential." Thus closes one of the most colorful chapters in the still-running ballistic missile serial: Army vs. Air Force.

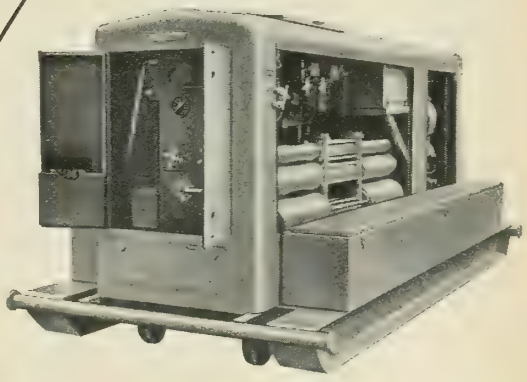
Col. Nickerson had been accused of espionage, perjury and failing to safeguard classified material. The more serious charges of espionage and perjury were withdrawn, however, when he pleaded guilty to the lesser counts.

Nickerson wrote "Considerations on the Wilson Memorandum," wherein he compared Army and AF progress in missile development and detailed why Army should have responsibility for firing Intermediate Range Ballistic Missiles. Little in the document would probably have been considered by a court of law as "classified" from a military security viewpoint. Politically, however, it was "too hot to touch." Col. Nickerson sent copies to selected Members of Congress, certain Washington columnists and MISSILES AND ROCKETS magazine.

Trouble began when a newspaper columnist caused it to be brought to Defense Secretary Wilson's attention. He demanded an immediate investigation by Army Secretary Brucker.

The crux of the prosecution's case, however, was not this document. In what was a completely unsolicited and apparently naive effort to provide m/r with background information on the Army's missile progress, he mailed certain official documents via registered mail to this magazine. Each was clearly marked "Secret" and was returned unread via registered mail to the sender. Army investigators, however, found a transcript of the covering letter from Nickerson to m/r. The prosecution based its main case on the fact that Nickerson sent these documents to unauthorized persons.

Col. Nickerson was fined $1500 and suspended in rank for one year. Huntsville citizens took up a collection to pay his fine and legal costs.



Redstone Equipment Stored Underground

HUNTSVILLE, Ala.—A housecleaning operation at one of the world's most modern scientific installations, Redstone Arsenal, has used ancient means to achieve its purpose.

River barges and caves are being used to store more than 500 tons of

Oil free high pressure gas

ORIGINAL DESIGNS

MINIATURE THERMAL RELAYS

with

99.99% PLUS RELIABILITY

New NORMALLY CLOSED RELAYS NOW AVAILABLE. Hermetically sealed by an exclusive process of bonding metal headers to high thermal, shock resistant glass housings. Designs are based on the "fuse burnout" principle and will open or close a circuit *positively* in 0.1 second or other delay times. They can also be safely used as a "squib" or timing mechanism.

Relays have been qualification tested for high performance and are being used extensively on current production missiles and complex electronic equipment.

Withstand extreme conditions of temperature (−100°F to +450°F), shock (250 G's), vibration (20-3000 cps at 40 G's), and precise electrical characteristics with the added feature of visibility.

Our complete environmental testing laboratory samples and certifies daily production.

WHAT ARE YOUR REQUIREMENTS?

heavy strategic production equipment which was shipped here following World War II for storage against possible future needs.

The Redstone Arsenal's Tennessee River docks were used for the first time for outbound freight in the shipment of 179 pieces of machinery, some weighing as much as 15 tons, via a circuitous but economical route to a vast cave near Atchison, Kansas, for storage. The operation is said to have saved the Army $20,000 as compared with the cost of other transportation.

The Redstone docks are normally used to receive shipments of materials from the atomic plant at Oak Ridge, Tenn., which is upstream on the vagabond Tennessee River that has its source in North Carolina and winds up as a tributary of the Ohio River near Cairo, Ill. The Ohio then flows into the Mississippi. The Redstone barges followed this route, turned up the Mississippi into the Missouri River and delivered their freight at Atchison above Kansas City. Five days were required for the operation.

The docks at Redstone are also used to receive shipments from the Muscle Shoals plants of Reynolds Metals Co.

First *Redstone* Battle Group Activated

HUNTSVILLE, Ala.—The first battle group for field operation of the big *Redstone* bombardment missile will be activated by the Army here on Sept. 9th. It will consist of about 600 men, a battalion divided into two batteries. Each battery will be equipped with one mobile launcher for the 60-foot missile.

The new group will be formed around the 217th Field Artillery Battalion which has been in training for a year to develop field operating techniques for the *Redstone*. The group will also include the 630th Ordnance Company and the 580th Engineer Company.

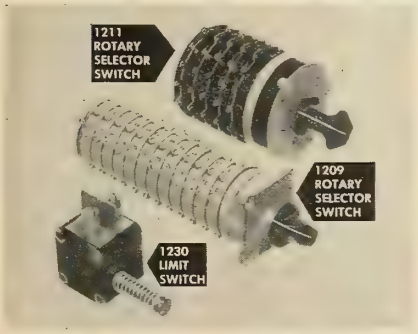
Lacrosse Course Concluded Aug. 6

HUNTSVILLE, Ala.—The Army will have 150 well-trained teachers for maintenance and fielding of the new *Lacrosse* anti-aircraft and artillery missile when a special course of instruction ends here in early August. They will be deployed immediately to White Sands Proving Grounds, New Mexico, to the Artillery Guided Missile School, Fort Sill, Okla., and to the Marine Corps where they will teach the missile techniques to other instructors.

Far Side: Bargain Counter Space Exploration

America's first stride into interstellar space will begin with the quiet softness of a gentle Kona breeze. In fewer than 60 days on a Polynesian atoll in the Central Pacific, a glistening 3,750,000 cubic foot polyethylene balloon will be hooked to its payload, filled with helium and at the precise moment, cut loose. Several hours later and 100,000 feet above the earth's surface, the four first stage motors of Project Far Side's space exploration vehicle will fire with a combined thrust of 160,000 pounds. The straining balloon will be ripped assunder, and for the next few minutes the tiny transmitter in the missile's nose will telemeter back measurements of space conditions within "the immediate environment of earth"—up to some 4000 miles out.

This will be the first of six Project Far Side firings planned for this fall. Though none will include a try at the moon, success of the series will certainly put this next on the list. It is a coming objective of major scientific importance.



MISSILES AND ROCKETS magazine announced exclusively in its April issue this year that AFOSR was working on various moon rocket projects. Far Side is the beginning. The details of this

MISSILES AND ROCKETS editors Norman Baker and Seabrook Hull examine cosmic ray sensor and circuitry to be launched with the instrumentation in Air Force Office of Scientific Research Project Far Side's space exploration vehicle. This circuitry is designed under contract by Maryland University. In the inset is the full instrument package with battery, transmitter, other circuitry. Aeronutronics Systems, Inc. makes the complete unit.

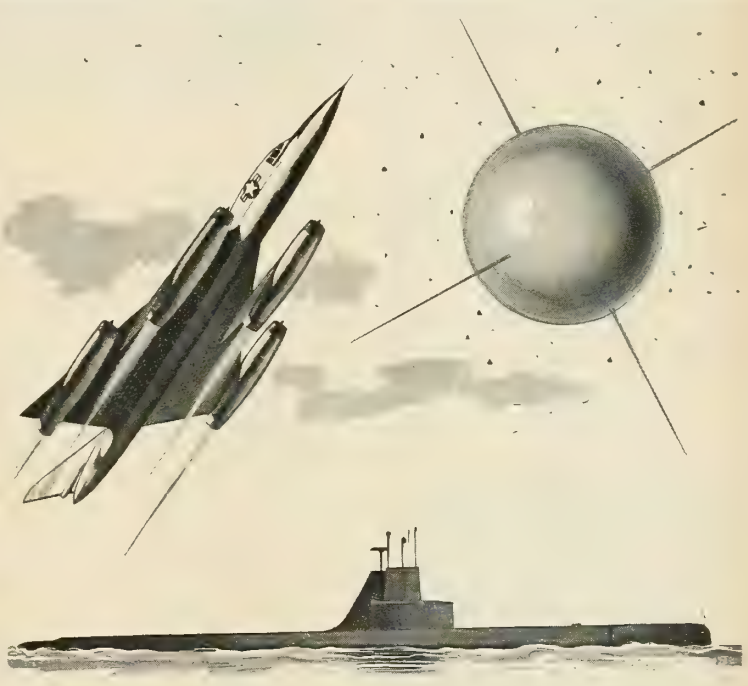
historic project have been confirmed to m/r by Brigadier General H. F. Gregory, Commander, Air Force Office of Scientific Research, Air Research and Development Command.

If Project *Vanguard* is costly and encumbered in a plethora of red tape, Far Side is pleasantly simple and might have lifted its cost figures out of a mail-order catalogue (see editorial, p. 11). Consisting of 10 solid propellant rockets divided 4-1-4-1 into four stages, the Far Side vehicle uses strictly off-the-shelf items.

Stage one consists of a cluster of four *Recruit* rockets built by Thiokol Chemical Corp. Stage two is a single *Recruit*, and is located centrally forward of the first stage. Stage three, tacked onto the nose of number two, is a cluster of four *Arrow II* rockets made by Grand Central Rocket Co. *Arrow II* is a souped up *Loki*. The fourth stage, a single *Arrow II*, is nestled concentrically in the third stage. Both the *Recruit* and *Loki* were originally developed under U.S. Army contracts.

Project Director Herbert L. Karsch, Aeronutronics Systems, Inc., examining forward end of the first and nozzle of the second stage of the Far Side vehicle. The motors are RECRUITS. Note last two stages beyond.

The overall length of the vehicle is about 23 feet. Its diameter ranges from less than two feet at the first stage (excluding cruciform fins of less than 20 inches net additional total span) to about eight inches for the second stage and less than 12 inches for the clustered third and fourth stages. The weight of the vehicle itself is 1900 pounds. Including its launching cage, external power supply and radio gear, etc., the weight that will be carried aloft by the balloon comes closer to 2300 pounds.



The balloon itself weighs another 1500 pounds and reaches a diameter of 200 feet at altitude. It was designed and is manufactured by the Mechanical Division of General Mills, Inc.

The Far Side rocket vehicle's payload will consist of an instrumented package roughly six inches long, four inches in diameter and weighing about three-and-a-half pounds. The main measurements to be made will be ion density, magnetism and cosmic rays. All will be single-purpose measurements. The entire instrument package will be enclosed in white foam of density three pounds per cubic foot. All circuits are 100 per cent instrumented.

Actual on-board cosmic ray instrumentation, including geiger detector tube, high voltage supply for the geiger counter, scale of 64 with associated preamplifier and emitter circuits. Power consumption is 100 milliwatts. In charge of this phase of the work is Maryland University's brilliant young astrophysicist, Dr. S. Fred Singer, described by AFOSR as "one of the nation's leading authorities in the field of upper atmosphere research." The instrumentation is being put together by University of Maryland students under Dr. Singer's direction.

The Ford Motor Co. subsidiary, Aeronutronics Systems, Inc., is prime contractor for Project Far Side and is responsible for designing, fabricating and firing the vehicles. Far Side Project Manager for Aeronutronics is Herbert L. Karsch.

Project Monitor for Far Side is AFOSR's Director of Advanced

We may have already solved your flexible ducting problem

Flexible's been solving tough ducting problems in many different fields for a great many years. And has engineered all kinds of special shapes and tubings in a wide variety of fabrics and coatings for unusual applications . . . a starter duct for jet aircraft, for example, as well as special ductings used in the missile field for ground support. So it could be that we already have the answer to your particular problem. If not, we'll put our research facilities, including our brand-new laboratory, to work immediately. If silicone ducting is called for, our special Silicone Department, working with automated machinery, is prepared to meet your specifications.

To find out how Flexible can solve your ducting problems, write us, outlining your requirements. Our engineers will be glad to put their experience to work for you. Write to Dept. 218.

Four-stage Far Side rocket plus its firing platform are mounted on a truck prior to hooking onto 3,750,000 cubic foot General Mills balloon in preparation for June test flight.

Studies, Dr. Morton Alperin, who emphasizes the importance of obtaining heretofore unavailable data vital to the AF of today and tomorrow.

The actual altitude that will be reached by the Far Side rocket can only be estimated. Current lack of knowledge of the precise density distribution at ultra-high altitudes makes reliable calculations difficult. However, the four stages will fire for a cumulative time of 26 seconds (eight seconds actual firing time plus coasting stages) with a maximum acceleration of 200 g's. During this period the missile is expected to achieve a velocity in excess of 17,000 miles an hour—out where Mach Number is a meaningless unit.

Those participating in the project forecast only that the final stage will achieve a distance out from Earth of "from 1000 miles to several times that distance."

If current estimates of "air" density in space and of the diminishing effects of gravity are anywhere near correct and if the solid propellant rockets work as they should in the pressureless, highly ionized environment in which they will be firing—the expected distance is calculated at between 4000 and 5000 miles. The mean distance of Moon from Earth is 239,000 miles.

However, at 5000 miles out, the force or acceleration due to gravity, is only a little over six feet per second per second, compared to 32 on the earth's surface, and reducing steadily with the distance from the earth's center. No official suggestions have been made by AFOSR that it would take only "a little more push" to get a vehicle into the Moon's gravitational field. However, some of those closely connected with the project have admitted freely that it is not beyond the limit of either current balloon or off-the-shelf solid propellant knowhow to use this method for either orbiting or impacting the moon.

Scientists recapture first project Far Side test load after it reached 106,000 feet before dropping back to earth by parachute. First business shot is scheduled for September.

Rocket Trends

by Erik Bergaust

MID-OCTOBER MAY MARK the "turn of the century" for U.S. missiles . . . Complete shake-up by that time by the Department of Defense is understood to have been ordered by the White House to eliminate duplications and to step up efficiency in development . . . Some will lose, some will win . . . *Triton*, for instance, might get the ax, although this may be due to the rapid advancement in solid propellant technology.

AIR-TO-GROUND MISSILE RACE is on. Air Force officials seem to think Rascal-type missile (with improved range, speed) will be the next thing for boosting our strategic retaliation capability. Tomorrow's big bombers (including our B-52s) will become missile carriers exclusively. Industry is now bidding on new air-to-ground bird . . . In the lead, coming down the home stretch: Lockheed and North American . . .

DID WE MISS THE BOAT IN THE IRBM-ICBM race with Russia? It is said that had we poured the same money into a solid propellant program, we could have had operational IRBM's and ICBM's by now. Just as the solid *Nike Hercules* is replacing *Nike Ajax*, we can do the same for the IRBM-ICBM. And we probably will . . .

UNDERWATER MISSILE RACE is getting hotter and hotter . . . look to lithium as important underwater missile "fuel". If you want some capital gains from promising chemical suppliers to the solid field you might want to try Foote Mineral, American Potash & Chemical, or Lithium Corp. They will be making all the lithium perchlorate which is the hottest item to hit the solid propellant field. AmPot is the favorite since it will also cash in on the boron fuels, though Foote is a major lithium supplier to AEC.

RELIABLE SOURCES SAY Standard Oil Co. (Ind.) wants somebody to take over its Seymour, Ind. activities for solid propellant work . . . American Rocket Co. is said to be seeking somewhat smaller pile for its current expansion program.

RED CHINA MAY BECOME SOLID ROCKET PRODUCER since they will buy the following important rocket chemicals from Britain and Norway: ammonium nitrate, cellulose nitrate, lithium compounds, potassium chlorate, potassium dichromate, potassium nitrate, potassium permanganate, sodium chlorate, sodium dichromate, sodium nitrate, and sodium perchlorate . . . University of Moscow is working on the acceleration of lithium, sodium, potassium, rubidium and caesium ions as potential space rocket propulsion systems.

DOUGLAS AIRCRAFT ABOUT TO BECOME LEADER of U.S. missile builders? Stepped-up NATO missile negotiations (most NATO missiles will be Douglas birds . . . *Nike*, *Honest John* etc.) and recent successful tests of AF's atomic MB-1 . . . plus BIG *Nike Hercules* contract coming up . . . indicate Douglas will take missile production lead for a good while.

COKEBOTTLE DESIGN CONCEPT (area rule) may be employed in missiles. Army missile men are reported to be considering Marilyn Monroe-shaped IRBM's and even ICBM's to lick early drag problems . . .

The *Vanguard* Engine Passes Qualification Test

As far as power plants are concerned, Project *Vanguard* is ready to go. At least that's the status insofar as static qualification tests are concerned. Three of the four *Vanguard* engines under contract to The Martin Co. have passed with flying colors. Rumors are, however, that the fourth company, Allegany Ballistics Laboratory (subsidiary of Hercules Powder Co.), wants out.

General Electric Co.'s long-in-doubt first stage engine, m/r has learned, passed its complete qualification test "without having to replace anything"—not one single part.

Aerojet-General, so far, has had two second stage engines accepted—the first on April 24 and the second on May 16.

Grand Central Rocket Co. has not only had its third stage engines accepted, but one has flown with "100 per cent perfect" results.

These facts remove a major factor of doubt from the possibilities of success of Project *Vanguard's* efforts to place a man-made earth satellite in an orbit during the International Geophysical Year. Though the need for refinements may become apparent as the first and second stage engines are subjected to actual flight tests, it must be heartening to Naval Research Laboratory and Martin that at least they work on the ground. It's a big step towards consummation.

GE's first stage engine has completed between five and ten full duration tests of 150 seconds each without any parts having to be replaced. GE believes that this places the life of their engine over that of any other engine of comparable performance. Nearly all the engines called for in the contract have been delivered.

Reason for failures of the first three engines delivered appears to be (believe it or not) that they had gotten rusty . . .

The fact that Aerojet General reports only two engines accepted so far indicates that this company is probably not so far advanced as GE in production. Development, however, appears to have been completed. *Vanguard* test vehicle TV-2 will probably be fired in a few days and will be the first flight test of GE's first stage. Soon thereafter, TV-3 will be fired, including a GE first and an Aerojet second stage. This should occur within six weeks.

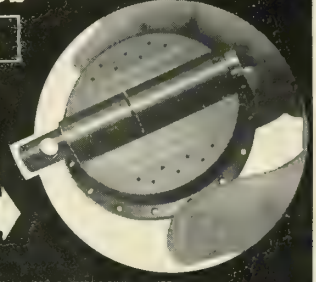
Aerojet-General, in developing the thrust chamber for its second stage engine, worked out a system of wire wrapped aluminum tube construction with amazing weight to size advantages. This system is regeneratively cooled.

Assuming everything else to be in a similar state of preparedness as these three engines, it would seem that the possibility of advancing the date for a first business try at getting the 20-pound sphere in an orbit has improved. Statements, however, from those in authority in the project continue to be cautious—"in the spring of 1958; before the end of the IGY, etc."

Meanwhile, unofficial Lockheed Aircraft spokesmen would have you believe that an upward misfire of the third stage of an X-17 had already placed man's first uninstrumented satellite in orbit. Concern grows lest Russia in fact places a satellite in orbit on September 17, the 100th anniversary of Soviet space flight pioneer Tsiolkovsky's birth. This would be embarrassing. Meanwhile, Air Force Office of Scientific Research is piling Army rockets together in an attempt to accomplish man's farthest excursions into outer space.

Recruit's and *Loki's* for Outer Space

Five *Recruit* and five *Loki* rockets will be assembled into four stages to complete the AFOSR's Project *Far Side* space flight vehicle (this issue, p. 45). Reliability of rocket powerplants should not be a factor threatening project postponement or malfunctions during actual launch operations. Evaluation test firings will be eliminated on Project *Far Side*. All shots will be for real.



And still there is no word of what Redstone Arsenal is doing with all its *Recruits*.

Ordnance Associates— Finest source of—

Reefing Line Cutters

Today's smallest and lightest for nylon line capacities of 125 to 6,000 #. Proven designs withstand missile shocks, vibrations and accelerations in excess of 600g's. Electrically or mechanically fired. Action is instantaneous or with time delay up to 20 sec.

Missile Business

By Seabrook Hull

SECRET CONTRACTS SECRETLY ARRIVED AT, lack of competitive bidding and tax supported facilities for private industry are main reasons behind current Congressional efforts to change military procurement rules. Some figures Congress doesn't like: Of $13.6 billion total military buying in first nine months, 1956, 92 per cent was by negotiation instead of advertised bid; 39 per cent was negotiated in secret; and 22 per cent required a substantial initial investment of government funds. All-told, 17 exceptions to normal procurement procedures had been invoked to justify these actions. Congress aims to cut that list sharply. Law may pass this year. It would hit missile procurement heavily.

Passage would make it tougher for Services to direct procurement where they want it to go, for whatever reason. Company contracting officers would have to get used to new rules, bid closer to the cost line and in general become adept at more rough-and-tumble ways of doing business.

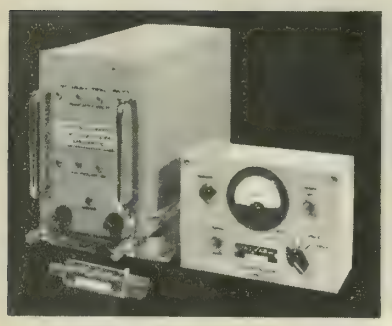
A PERMANENT ARMS INDUSTRY—anathema though it may be to traditional American concepts—may be the best answer. Business and procurement methods that work best in temporary all-out conditions of a conventional "hot war" obviously leave much to be desired over 20-to-50 years of cold war. A really comprehensive new look may be required.

FOREIGN SALES OF U.S. MISSILES will be largely handled through regular U.S. military channels. This doesn't mean, however, that it wouldn't pay U.S. missile makers to do a little personal salesmanship with NATO officials in position to make decisions. This could influence NATO-wide determination of West European missile requirements.

Two countries for sure, Britain and West Germany, and maybe Luxembourg, will pay their own way and may buy directly from manufacturer.

Only missiles that have been announced as being "cleared" for export are *Nike*, *Matador* and *Honest John*.

Possible big market exists for enterprising missile maker that comes up with a low-cost "prestige" missile for sale in Middle East, South America. These countries would like to have their armed forces geared to the missile age but could never afford high-cost, complex birds such as those being developed for U.S., NATO, etc.



MEANWHILE, COMPETITION PATTERN IN MISSILES develops. Japan's applied for permission to manufacture Swiss Oerlikon-56 rockets. French have radio-guided anti-tank SS-11, renamed it SS-22 and are trying it out as an air-to-air missile. Norway boasts air-to-underwater *Tern*. Sweden is buying Australian ground-to-air *Jindiviks*. Prices count abroad.

DEATH OF *NAVAHO* plus forecast death of Navy's *Triton* project carry serious implications for "next step" development in air transport; could kill all development on large ramjets. Similarly, one of most practical approaches to regular manned space flight involves attainment of initial high velocity with ramjets before cutting in ion propulsion. There are other factors, both military and civil, that leave proposed abandonment of advanced air breathers open to serious doubt. Development of effective anti-ICBM missile will obsolete a lot of costly hardware overnight, and cause a serious flip-flop in the balance of power—unless U.S. has something else in its arsenal, like *Navaho* or *Triton*.

Hughes Latest *Falcon* Has Infra-red Seeker

The latest in the *Falcon* GAR air-to-air missile series is now in operation as a U.S. Air Force defense weapon. New *Falcon*, GAR-2A, is equipped with an infra-red radiation seeker greatly increasing the kill rate over earlier *Falcons*. GAR-2A is actually a GAR-1D with the IF guidance system replacing the radar system.

All-weather interceptors, F-102A, F-89H, and F-101, will carry both IF and radar equipped *Falcons* to insure kills under all weather conditions. Missiles will be fired in salvos of three to six as a condition of calculated kill

probability of 80-90%. The pilot may select the type and number of missiles to be fired once the control system has established the target.

Air Force officials announced that they would continue to hold the Navy *Sidewinder* in high regard as armament for day fighters. "The *Sidewinder* is a more simple weapon while the *Falcon* GAR-2A is more sophisticated and versatile". Main objection to the *Sidewinder* apparently is its length—requiring external installation.

Test firings of the new weapon were made at Holloman Air Development Center, N. M. For these tests *Matadors* and F-80s served as targets. Although all tests were conducted without warheads, each intercept destroyed the target.

INTERNATIONAL NEWS

By Anthony Vandyk

Swiss Reveal Details of Oerlikon AAM

Oerlikon has released full information on its 5-cm and 8-cm aircraft rockets with folding fins. These rockets are for use not only against aircraft but also against ground targets such as armored vehicles, armor trains, artillery. Oerlikon describes the distinctive features of its armament as: (1) quickness in action; (2) excellent accuracy; (3) high lethal power. It points out that the rockets are: (a) safe to transport; (b) capable of being stored for an indefinite period; (c) extremely safe to handle.

Multiple launchers are used for the rockets. The launchers are made in various shapes (one was illustrated in the July m/r, page 83) and with various capacities according to the type of aircraft and mission required. A typical launcher containing 76 5-cm rockets weighs about 660 lbs. empty or 1200 lbs. loaded. The launcher has no effect on the flight characteristics of the aircraft except for slightly reducing speed. It may be dropped in emergencies.

The rockets are electrically ignited by means of a selective triggering built into the cockpit and can be fired singly or in automatic fire. To avoid mutual interference during flight when firing in automatic fire, the rockets are fired in pairs at time intervals of 0.1 seconds.

During a demonstration for a foreign air force Oerlikon reports that 72 5-cm rockets with folding fins were fired from Meteor Fighter in a series of automatic firings from air to ground to demonstrate the killing power and firing accuracy of the weapon. The firing started at altitude of approximately 4000 ft. and ended at an altitude of about 1500 ft. The total firing time was approximately 3.5 seconds. The rate of fire is equivalent to 1200 rockets per minute. During the demonstration the rockets were dispersed over an area about 60 ft. long and 25 ft. wide. A total of 24 hits were made on a cloth target measuring 19 ft. by 19 ft.

The following technical data referred to the 8-cm rocket with folding fins: initial weight, 20½ lbs.; maximum velocity (fired from ground), 2756 ft. per second; weight of explosive (Hexal), 2 lbs.; thrust (approx. 1 second), 1587 lbs.; burning ends after approximately 1411 ft.; length of rocket 3 ft. 11¾ in.; armor guessing ability, 1 ft. 2½ in.

The rocket is manufactured by Oerlikon in the following versions: practice rocket (inert), practice rocket with marking charge; explosive rocket with impact fuze; and armour piercing rocket with hollow charge.

The folding fins open approximately 0.05 seconds after leaving the launching tube. During this period the rocket covers a distance of approximately 10 ft.

The characteristic properties of the rocket motor are: rocket motor with parallel beam jet; spring actuated folding fins in which all fins open

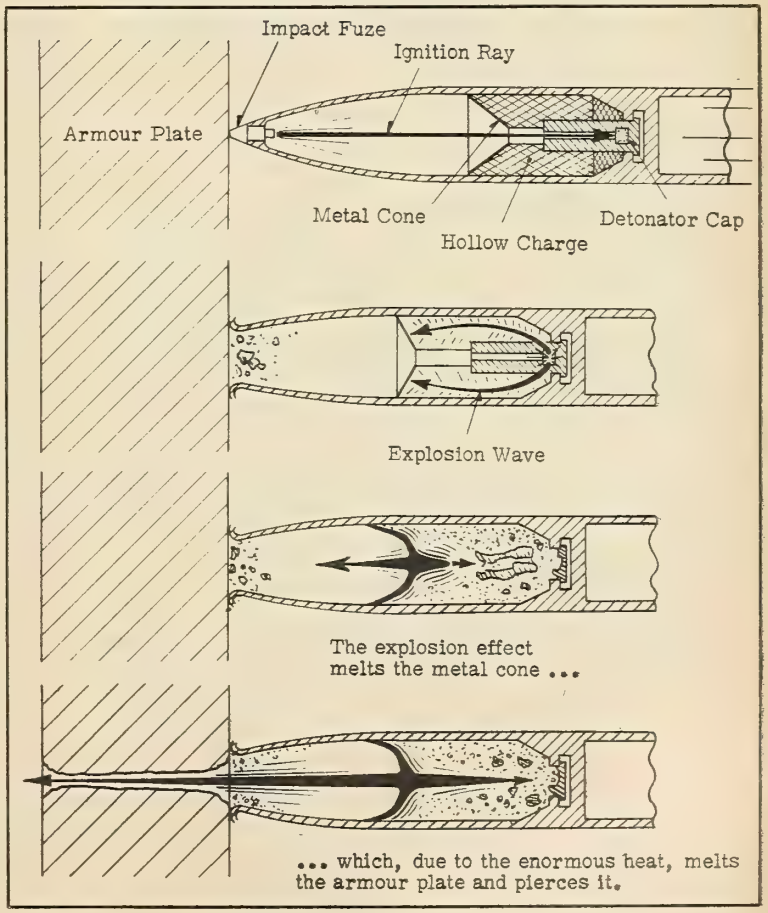

Diagram shows how a rocket with hollow charge operates as an armor-piercing weapon.

simultaneously by direct action; slight twist due to guide veins inside the nozzle; and electric ignition by means of a contact ring at the end of the nozzle.

Mitsubishi Electric Machinery Co., Ltd., has applied to the Japanese government for permission to pay Buehle Contraves & Company of Switzerland for the patent rights for the production in Japan of Oerlikon guided missiles. A provisional agreeement gives Mitsubishi all the patent rights for the production in Japan of the *Oerlikon-56* and its fire control system.

The Swiss firm is asking 8% as patent rights of the *Oerlikon* missiles and 5% of the revenue from sales of launchers and firing control system. The contract is to be valid for 15 years. It will be two or three years before Mitsubishi can start mass production in Japan of guided missiles because of government permits, preparations and completion of final contracts with the Swiss firm.

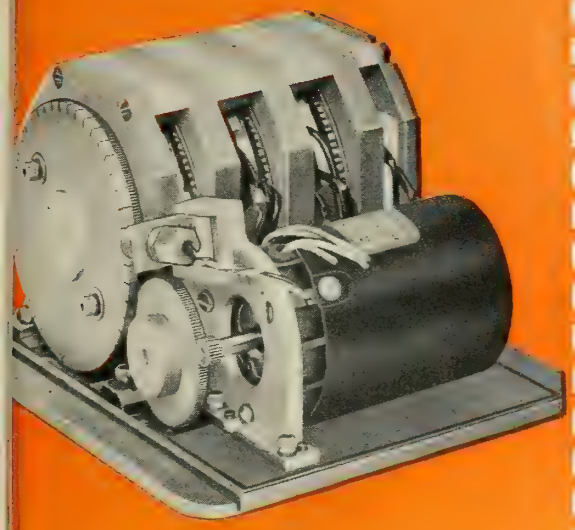
The Japanese Defense Agency this fall will import a complete set of *Oerlikon-56* rockets and a launcher from the Swiss firm at a cost of $1,080,000 with the aim of studying and testing the Swiss weapon.

Soviet Space Plans Spelled Out

From the various statements by Soviet officials and scientists, particularly from Academician Eugene K. Fedorov, chairman of the IGY's Soviet committee for rocket and satellite research, and his associate I. P. Bardin, we glean the following items regarding the artificial Soviet satellite to be launched into outer space:

There will be several such satellites, of varying weights and sizes, but the average diameter will be about 18 inches.

Each satellite will be launched at a slight angle to the meridian. Its speed will be 18,000 miles an hour. It will complete its circle of the globe in about 90 minutes. Its orbit will cover almost the entire globe. It will travel near but not over the Arctic and the Antarctic.



Aboard the best of their satellites the Soviets will install equipment to measure the air's density; the number and energy of micrometeorites; the composition and energy of cosmic rays, electrons, gamma rays, and rays causing the Northern lights. Radio-television will automatically relay this data to the earth.

Since relay energy on some of the satellites will be limited, the information will be signalled only at certain intervals.

IGN ACHIEVEMENTS WITH SUPRAMICA* ceramoplastic

RELIABILITY DOES NOT COST EXTRA

MYCALEX* TM commutation switches set new standards of reliability for aircraft and missile telementry

$25,000 a minute is costly time — but that is the estimated value of the final "count-down" for a major missile test.

Telemetered information will record the vital history of the flight and point the way to new developments and advancements. To achieve complete control, absolute dependability and long life, precision equipment is essential, both during flight and during the "count-down" when a complete check-out is demanded. Cleaning and adjusting commutators during the final hours or minutes of "count-down" is expensive — and wasteful.

MYCALEX* TM commutation switches with precision molded commutator plates of SUPRAMICA 555 ceramoplastic introduce new standards of reliability to this important operation. Hundreds of hours of **completely unserviced life** with dependable, low-noise-level signals is definitely attainable. Customer evaluation tests have shown satisfactory operation of MYCALEX TM switches for over 1000 hours at 1200 RPM with only brush cleaning and routine maintenance.

These exceptional performance standards are possible because of painstaking precision assembly and testing, and the use of SUPRAMICA ceramoplastic commutator plates, which have total, permanent dimensional stability and will withstand temperatures as high as 500 degrees C. without distortion or contact loosening.

MYCALEX TM commutation switches and SUPRAMICA ceramoplastics are making significant contributions to the reliability and durability of electronic equipment for military and civilian applications.

Write for detailed information.

*MYCALEX and SUPRAMICA are registered trade-marks of Mycalex Corporation of America. 555 is a trade-mark of Mycalex Corporation of America.

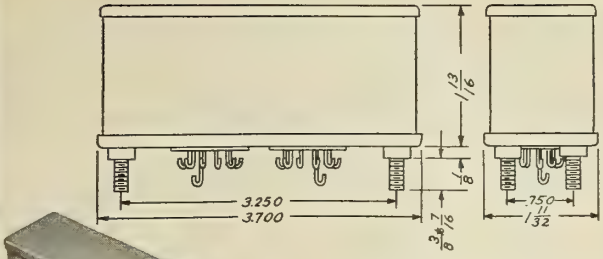
*KG RELAY (Pat. Pending)

ONLY 2.0 WATTS AT NOMINAL VOLTAGE FOR 12 MILLISECONDS EFFECTS ARMATURE TRANSFER

NEW
POTTER & BRUMFIELD
KG SERIES RELAY



The new KG magnetic latch relay was designed by P&B engineers at the insistence of leading aircraft and missile manufacturers and their suppliers of control systems. A permanent magnet which locks the armature into position is the secret of the KG's dramatically high resistance to shock and vibration.

In addition to withstanding 30g vibration from 6 to 2000 cps, tests show the contacts will open for no more than 80 microseconds during 100g shock.

Armature transfer from one set of the 6PDT contacts to another can be made in approximately 12 milliseconds with only 2.0 watts at nominal voltage. The KG is rated for ambient temperatures from −65°C to +125°C.

The KG, together with other relays in the P&B "Star Series", has vastly increased the realm of relay reliability for critical applications demanding positive action of all components. Write or wire today for complete technical data.

POTTER & BRUMFIELD, INC., PRINCETON, INDIANA—SUBSIDIARY OF AMERICAN MACHINE & FOUNDRY COMPANY

STAR SERIES

KG RELAY

DESIGNATION: KG23DBH

GENERAL: Insulating Materials: Teflon, glass and ceramic.
Insulation Resistance: 100 megohms min.
Breakdown Voltage: 500 V. RMS.
Shock: 100g where contact openings less than 80 microseconds may be permitted.
Vibration: 30g 5 to 2000 cycles.
Ambient Temperature: —65°C to +125°C.
Weight: 13 ozs.
Pull-in-Speed: 12 MS using 310 ohm coil at 24 V. DC. (25°C).
Terminals: Two 11 pin multiple solder headers with hook ends for 3 #20/AWG wires.
Enclosures: Hermetically sealed only.
Dimensions: 1-11/32 x 3.700 x 1-13/16 (See drawing for width, etc.)
CONTACTS: Arrangements: 6 pole double throw.
Load: Dry circuit to 3 amps, 115 V. AC, resistive. 5 amps, 28 V. DC, resistive.
COIL: Power: 2.0 watts at Nominal Voltage.
Duty: Either coil may be left energized without damage to the relay.
Insulation: Teflon tape.
MOUNTINGS: Four 3/8 inch #8-32 studs on 3¼ x ¾ inch centers.

COIL DATA:(EACH COIL)

Voltage:	6 V. DC	12 V. DC	24 V. DC	48 V. DC	110 V. DC
Resistance: ±10% @ 25°C	14 ohms	55 ohms	310 ohms	835 ohms	5500 ohms

Russians Study Cosmic Medicine

Cosmic medicine, Russians explain, is that new branch of aviation medicine which deals with the effects of heights and speeds upon man in his future rocket flights. A recent issue of *Sovetskaya Aviatsia* devotes an article on this subject by V. Malkin, described as "candidate of the medical sciences," a physician with an advanced degree.

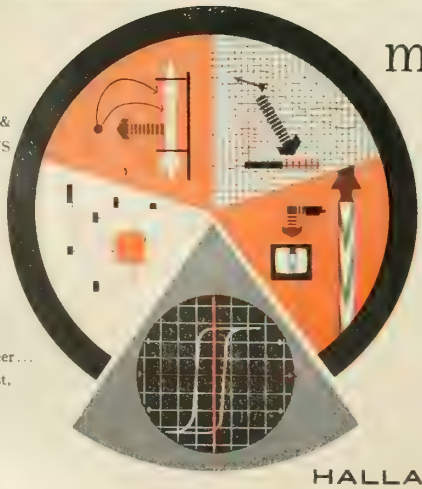
Having ascended to a great height and having overcome the force of the earth's gravity, a rocket will "come out to its cosmic trajectory, its motors will cease their work," and its astronautic personnel "will find themselves in a state of imponderability, that is, without weight," writes Dr. Malkin.

Already now, the Soviet physician points out, in experimental flights within the limits of the stratosphere it is possible to create these conditions for a period of two to three minutes. This is because in such flights "made along a parabola" the centrifugal force for a time balances the force of the earth's gravity. Experiments with aviators have already shown that some men can successfully withstand the effect.

Several tests have been conducted where the pilot experienced the condition of weightlessness for several seconds.

Red Rockets for Venus

Russian scientists expect to send unmanned rockets to Venus within the next ten years. Instruments in the rockets, according to Radio Moscow, will record photographs of the planet's surface before it lands in order to prove or disprove the existence of life on the planet.



To ponder the question of what plants and other low forms of life may or do exist on Mars and other planets involves no idle theorizing, say the Soviets. Such discussion has a highly practical relevance since we are on the threshold of journeys to those planets and our interplanetary travelers of the bright tomorrow must indeed know what life, if any, they may encounter on Mars, Jupiter, Saturn, and Uranus and whether they themselves can survive there on landing.

This is the opinion of Professor G. A. Tikhov of the Alma-Ata Observatory in the Soviet Kazakhstan in Central Asia, in charge of the Astrobotany Sector of the Kazakh Academy of Sciences. He reveals that "one of the basic conclusions of our observations is that Mars does have plant-life, which circumstance we can announce with sufficient certainty."

missile outbound

Small as a portable radio...1/6th the size of a conventional vacuum tube unit of equal capacity...the Hallamore "Iron Autopilot," now in quantity production, amplifies guidance signals to provide positive impulses directing the missile along its flight path. Similar solid state devices are under constant study and development by Hallamore's Magnetics Group, providing the answers to difficult space and environmental problems encountered in the nation's missile program. Hallamore Electronics performs contracts for the United States armed forces and for prime contractors in the fields of missile ground support and instrumentation systems, audio and visual communications systems, electronic components, and magnetic products.

World Astronautics

By Frederick C. Durant III

A number of member societies of the International Astronautical Federation have local sections in various parts of their country. At last count the ARS has 31. The DGRR of Stuttgart has branches in Baden-Wurtemberg, Berlin, Hamburg, Hannover-Niedersachsen, Hessen, Nordbayern, Nordheim-Westfalen, Oberbayern, Saarland and East Germany. The British Interplanetary Society has 5 sections: Midlands, North-Western, Scottish, Western and Yorkshire. The Palskie Towarzystwo Astronauticzne of Warsaw has sections in Cracow, Wrocaw, Bydgoszcz and Katowice. At last report the Yugoslav Astronautico Drustvo based in Belgrade has a branch in Zagreb with groups forming in Sarajevo, Skopje and Ljubljana.

•

The DAR rocket group of Bremen has announced plans for a fifth anniversary celebration 27-29 September. The firing of solid propellant oil-spray rockets (m/r April '57, p. 88) will be a feature of the program.

•

The German Museum of Munich is reestablishing an Aviation Wing and is searching for historical material. The search is on to locate rocket weapons captured by the Allies which might be made available for display. The remarkable rocketry achievements of the Germans during World War II represent a significant period in the evolution of astronautics. It seems appropriate that technical evidence of this historic work be assembled for posterity.

•

Correspondence and contacts in Korea, Greece, Rumania, India and Pakistan indicate interest and a desire to organize astronautical societies in these countries.

•

Academician Leonid I. Sedov, President of The Commission of Astronautics of The Academy of Sciences, Moscow, attended the Third Symposium on Cosmical Gas Dynamics at Cambridge, Mass., recently.

•

A few years back it was possible to add to one's library every new book pertaining to rockets and space flight without straining the pocketbook. Such is no longer the case. Recent publications, however, include some musts. Willy Ley's *Rockets, Missiles & Space Travel* (Viking Press) has appeared in a new edition, enlarged and updated. As a reference work it has no peer.

•

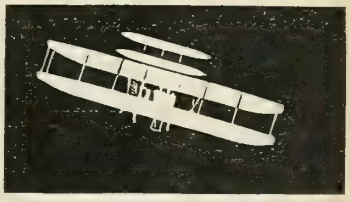
Criterion Books has just published *Man Among the Stars* by German science writer Wolfgang Mueller, translated from his successful *Du Wirst die Erde sehn als Stern*. Mueller is not hesitant to contemplate upon historical trends, psychology, religion and philosophy and their relationship to astronautics.

•

The Navy officially opened the U.S. portion of International Geophysical Year by firing a *Dan* rocket to an altitude of approximately 75 miles from the San Nicholas Island facility of their Air Missile Test Center, Point Mugu, California. The rocket, one of 14 to be fired during the next few months, is equipped with 20 pounds of instrumentation for the study of Lyman alpha radiation, "soft" X-rays of one to two Angstroms in magnitude and gamma rays emitted during solar flare periods. It is hoped that the results of the firings, when integrated with other measurements made during the IGY investigations by the 62 cooperating nations, will enable scientists to determine the relationship between solar flares and radio fadeout.

An Important Opportunity for the

SENIOR SPECIFICATION ENGINEER ICBM and IRBM



This position involves directing the development of complete weapon system specifications at the policy level. The specification program will incorporate propulsion, air frame, guidance and warhead requirements at levels ranging from top specifications to detailed component and sub-system specifications.

This activity is an important aspect of Ramo-Wooldridge's over-all systems engineering and technical direction responsibility for the Air Force Ballistic Missile program.

Please address inquiries regarding this technical management position to:
Mr. W. J. Coster

The Ramo-Wooldridge Corporation

What's going on up there?

American Electronic's new 300 KC Band Width RECORDATA magnetic recording system gives an accurate, permanent record.

Specifically designed for recording data from satellites, missiles or other projects where extreme accuracy is required, RECORDATA offers a new concept in reliability and versatility. This sixteen channel system with its modular construction offers many unique features. For example, the six standard tape speeds of 1⅞, 3¾, 7½, 15, 30 and 60 inches per second can be instantly selected with a single switch without changing belts or pulleys. Special speeds to 240 inches per second are also available. Automatic controls assure constant tape tension from beginning to the end of the reel, regardless of size.

Quickly interchangeable tape guides accommodate ¼" ½" or 1" tapes. The plug-in magnetic head assemblies are extremely accurate and provide data tracks with the best electrical uniformity. Where fidelity and reliability are necessary in a data recording system you can depend on RECORDATA . . . manufactured by American Electronics whose Concertone Hi-Fi tape recorders have been famous as quality leaders. Write to Dept 40At for complete technical information.

Have you heard about the wonderful Engineering opportunities at AMERICAN?

Three Missiles Produced By French Firm

SNCA du Nord, one of the larger French manufacturers, has given some information on the production status of its missiles. The SS-10, SSM, and the CT-10 target missile are currently in production. The former is designed as an anti-tank weapon. The French company states that it will soon start production of a refined version of the SS-10, the SS-11. Also to go into production is an improved CT-10, the CT-20. The third new production item is the Nord 5103, an AAM. SNCA du Nord expects to receive export orders for its three new production missiles in addition to contracts from the French government.

For its expanded production program, SNCA du Nord will enlarge its facilities at Bourges and will hire more staff. The company at present employs a staff of 8000 at its four plants—Bourges, Les Mureaux, Meaulte and Chatillon.

SNCA du Nord's reports give no details of future projects other than mentioning the fostering of "important developments" and the "confirmation of the future of the company in the field of missiles."

The company regrets that its Gerfaut and Griffon experimental aircraft are not to go into production but it stresses that the experience obtained with ramjets due to use of these aircraft will be useful in the development of future missiles.

Animal Experiments Announced by USSR

Experiments with small animals sent up in rockets (dogs in the Soviet Union, monkeys and mice in the U.S.) have already yielded much valuable data on the physical state of the animals when the latter became "non-weight" for a few seconds or minutes. The rockets' automatic equipment gave doctors the information they needed on the animals' breathing, blood pressure and heart behavior.

Dr. Malkin declares that each such animal's "vestibular apparatus, that is, the nervous system signaling to the central nervous system about the body's position in space," was substantially disturbed in its functions and thus played an important role in the disorientation of the animal while in rocket flight.

But the most worthwhile experiments so far in "cosmic medicine" involve man's imponderability or non-weight status. Dr. Malkin writes of 16 aviators achieving this non-weight condition during a special experimental flight, for 30 to 45 seconds at a time.

Behind the Curtain

By Dr. Albert Parry

One fact above all others is apparent from the latest Kremlin shakeup: Without Zhukov and the other marshals standing behind him, Khrushchev could not have won. However, Zhukov strengthened the political role of the Soviet armed forces even more than he consolidated Khrushchev's power and policies. The Soviet military may not want war, but they certainly want more "diverse atomic and hydrogen weapons, powerful rocket and jet armament of various kinds, including long-range rockets."

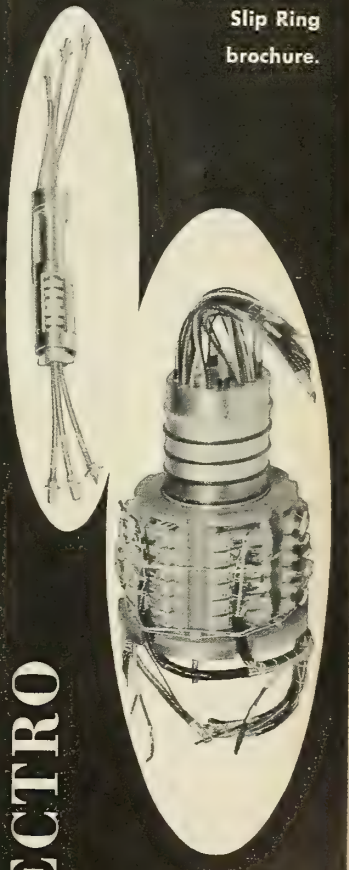
But Soviet *talk* of peace is always with us. The current Sixth Five-Year Plan, 1956-60, calls for "a considerable expansion of titanium production"—for peaceful aims only.

Comrade F. Kharakhorin in the Moscow *Trud* presented an article with the significant title; "Titanium, the Metal of the Future." He declared that the USSR's titanium industry has been created comparatively recently, since World War II. "From the carbide of titanium and wolfram, with the addition of metalic cobalt, alloys are obtained whose hardness is nearly that of diamonds. These remarkable materials for cutting instruments are being prepared at the Moscow Combinat of Hard Alloys."

Yet, fangs are bared from time to time in no uncertain manner. The very day that Danish Defense Minister Paul Hansen announced in Parliament that Denmark had accepted the American offer of *Nike* and *Honest John* guided missiles, as part of the joint defense aid program, and that the Danes would be given U.S. missile training, radio Moscow blared (in English) that something was rotten in the capitalistic Kingdom of Denmark also, that Denmark was creating "a grave menace" for herself by accepting U.S. guided missiles, and that the future might bring upon Denmark "the retaliatory blows meant for an aggressor."

Krokodil, Moscow's humor magazine, attacks a Florida travel bureau for running an ad in the *Miami Herald* announcing "sale of tourist tickets for the moon, Mars and Saturn, first such flight now planned for 1987." The Red satire periodical, accuses the Florida concern of "profiteering". But it also argues that the 150 Americans who responded to the ad must have been attracted by the promise that "no passports will be required . . .

Red Prague officially announces its gratification that "the U.S. has chosen a star map made by Dr. A. Becvar of Czechoslovakia for recording the position of its satellites."



The Czech government also claims a geophysical laboratory some 4500 feet below ground (in a mining pit at Brezove Hory), believed to be the deepest observatory in the world. It is equipped to register movements of the earth's crust caused by the force of gravity of the moon and the sun. The depth provides freedom from surface disturbances.

An electronic computer of the Soviet Academy of Sciences "can click out in a day or a week that which a hundred mathematicians can solve only in a year." This is revealed by V. Safonov in recent issue of the Moscow *Literaturnaya Gazeta.* He adds, however, that it is used only to some 20 per cent of its capacity. The other 80 per cent of the wonderful electronic brain remains idle until Red rocket men have more theories for the machine to test and new tasks to perform.

The Soviets are now considering the proposal of some of their astronautic scientists to reorganize the Lesgaft Natural Science Institute in Leningrad into the Institute of Cosmo-Biology, to study "all problems connected with a possible development of life on other planets, also with conditions of human existence in and en route to such worlds."

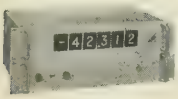
NOW! A REVOLUTIONARY NEW CONCEPT IN PRECISION DIGITAL MEASUREMENTS OF AC, DC, Ohms and RATIOS

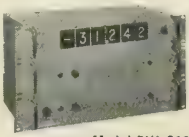
New E-I transistorized plug-in modules give maximum flexibility for custom applications with standard off-the-shelf modules.

This latest E-I development provides the maximum versatility in digital instrumentation. From a few basic modules a host of instruments can be constructed. Basic modules never become obsolete. To do new jobs, simply add new modules. Equipment can be easily kept current at minimum cost and engineering.



But versatility is only part of the story. These new modules also boast dramatically new engineering specifications, fully transistorized circuits and numerous other features which were incorporated as the result of our experience with more than 1,000 digital instruments in the field.

Your E-I representative has complete information on this latest E-I development. Ask him about it... today!



Any precision instrument for measuring DC, AC-DC, Ohms, DC and AC ratios can be constructed from these five basic units!

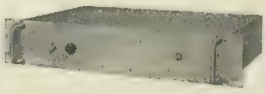
whether it be a DC digital voltmeter...

Model DVA-500

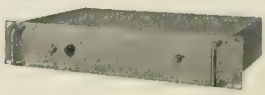
an AC-DC digital voltmeter...

Model DVA-510

or a complete check-out system.



BASIC MODULES



Universal Power Module
Supplies all power and reference voltages for other E-I modules. Power and reference supplies and stepper drive amplifier are transistorized. Powers one or more modules.
Automatic calibration; stability of 0.01% from 40° to 125° F.; input power: 115 volts, 50 to 400 cycles.

DC Switch Modules, 4 or 5 digits
Visual in-line read-out of digits, polarity, decimal point. All contacts accessible at rear panel connector. Front and rear panel input connectors. Power supplied by Universal Power Module.

DC Pre-Amp Module
Input: 1 range scale, gain of 10.
Output: 0.001 to .9999 volts.
Linearity: 0.01%.
Gain Multiplication Accuracy: 0.01%.
Input Power: 115 volt, 50 to 400 cycles.
Drift: 10 microvolts per hour.

AC — DC Converter Module
A fully transistorized AC — DC converter.
Accuracy: 0.1% of reading, or 2 mv.
Frequency Response: 30 to 10,000 cycles.
Range: .0001 to 999.9 volts.
Zin, AC: 1 meg. on the 1 volt scale, 10 megs. on other scales; 20 mmf.
Ranging: Automatic
Reading Time: 3 seconds, average.

Resistance Switch Modules, 4 or 5 digits
Contains balance circuit, bridge ratio arms.
Provides visual in-line read-out digits, range.
All contacts accessible at rear panel connector. Power supplied by Universal Power Module.

New short form catalog now available. Write for yours today!

Washington Spotlight

By Henry T. Simmons

Cancellation of the North American *Navaho* program last month came as no surprise to those familiar with the Air Force's financial plight. The strictures on USAF spending dictated elimination of a major project and military logic did the rest. *Navaho* was mousetrapped between the Northrop turbojet *Snark*, which should be operational by 1959 and the intercontinental ballistic missile which *may* be operational by the early 1960's. The decision may be a wise gamble, but few would argue that it is a comfortable one. It means the U.S. won't have a supersonic intercontinental missile delivery capability until the ICBM materializes—and that, unhappily, may be long after the arrival date now scheduled.

•

The *Navaho* flight test program was plagued by an unusual share of bad luck. Four XSM-64 test vehicles have been fired from Patrick AFB, Fla., since last December and all failed. No. 1 aborted because of the failure of a rate control gyro; No. 2 tore away part of its launching apparatus, lost booster thrust and failed to ignite its ramjets; No. 3 burned up when the boosters quit inexplicably after a couple of seconds. On the fourth and last attempt in June, the booster motors fired for 42 seconds and then quit. Though the vehicle was traveling at an estimated velocity of Mach 1.6, this still wasn't fast enough to light off the big Curtiss-Wright ramjets.

•

Additional firings of *Navaho* test vehicles may be authorized by the Air Force for research purposes if costs can be held down. It is understood that North American has about 12 more XSM-64's in various stages of completion. Assuming NAA can lick the premature stoppage of its booster motors and accelerate the vehicles to the ramjet ignition point, the remaining XSM-64's could provide valuable data on the behavior of large ramjets under true environmental conditions.

•

Loss of the *Navaho* program means that Rocketdyne has no home for the three-barrel, 400,000-pound-thrust booster it has developed for the SM-64 production *Navaho*. The powerplant has been described as extremely reliable in static tests. NAA may propose that the engine be used in the first stage of a souped-up *Titan*, replacing the 300,000-pound motor Aerojet is developing for that purpose.

•

On its first flight in June, the *Atlas* ICBM test vehicle reportedly maintained structural integrity under stresses ranging up to 22 g's. The stresses occurred during the two loops the rocket performed after fuel starvation shut off one of the two motors. The Air Force is understandably pleased by the performance because the structure of the bird has been pared to the limit to insure maximum mass ratio. Example: it must be pressurized during transport to prevent distortion of the fuel tanks.

•

The Navy's decision to settle on a solid-propellant motor for its air-to-surface *Corvus* missile reportedly dealt the death blow to USAF interest in the project. The airmen aren't satisfied with the range of the Navy version, and they see no growth capability in the solid-propellant configuration.

ENGINEERS...

MAC presently has stimulating engineering positions available in a great variety of fields including:

This **New** High Impedance Resolver by Norden-Ketay controls the Terrier missile from a rolling deck

Developed by Norden-Ketay for Navy Bureau of Ordnance

Take the computer problem in aiming a supersonic missile from solid ground — add the variable factors of a rolling ship and a jet-propelled, airborne target. The answer to that problem combines **30** Norden-Ketay precision resolvers in a phenomenal computer capable of launching the Navy's 'Terrier' with incredible accuracy.

Norden-Ketay standard 105D2V Resolver met these difficult requirements perfectly for the Navy's 'Terrier' project — again demonstrating the value of the special characteristics designed into all Norden-Ketay components.

If your problem concerns computer accuracy or power, consider Norden-Ketay Resolver advantages. The high impedance circuitry requires smaller volume and reduces the size of power supply equipment.

The high degree of accuracy and reliability of this new resolver helps the designer achieve new levels of performance in computer systems. Here is an outstanding example of the way Norden-Ketay developments simplify the solution of complex problems.

General Specifications

Norden-Ketay Type: 105D2V • Designated by BuOrd as Mark 4 Mod 1
Tuned Input: 12,000 ohms • Accuracy: ±0.1% • Frequency: 400 cps.

. extending man's capabilities .

MAGAZINE OF WORLD ASTRONAUTICS

m/r exclusive:

Solid Fuel Industry Round-up

By the Editors of m/r

IN 1936 AN INFORMAL group, headed by Dr. Theodore von Karman, was formed at the California Institute of Technology (GALCIT Project) for research on rockets. Modest solid propellant work was undertaken. Two years later, in December 1938, General H. H. Arnold, Commanding General of the then Army Air Corps, asked Cal Tech to come up with a program to develop rockets for boosting aircraft.

It was not until July, 1939, however, that the program got underway at Cal Tech under National Academy of Science sponsorship. The Army Air Corps assumed sponsorship in July, 1940. By 1941, a successful solid RATO (rocket assisted takeoff) was demonstrated and the Aerojet Corp. (under Andrew Haley) was formed to produce the solid rockets. In 1943, the ORDCIT Project was launched to develop long-range rocket missiles. Also in 1943, the US Naval Ordnance Test Station at China Lake, Calif. was established (at a cost of over $100 million).

Under OSRD some $100 million was spent on various rocket projects during World War II. These projects developed such solid rockets as the Bazooka, a full line of aircraft and artillery rockets, the *Privates A* and *F*, and the large *Tiny Tim* 11.75-in. aircraft rocket. In 1946, the Jet Propulsion Laboratory was established at Pasadena at a cost of about $3 million.

From these humble beginnings has grown a vast solid propellant framework of governmental agencies (Table 1) and an industrial and research team (Table 8). From the original Aerojet group there are now over a dozen private companies engaged in various phases of solid propellant rocket activity. Most are under ten years old—and the average is nearer five years. A run-down on the latest activities of the industry-research team follows.

Solid Rundown

AEROJET-GENERAL: Now a subsidiary of General Tire & Rubber, Aerojet now accounts for 40-50% of revenue. Latest developments: A static firing of Polaris; lowering of RATO cost to under $200 each for a one thousand pound thrust, 15 sec unit; also, development of a low-cost ammonium nitrate solid propellant using oil-extended synthetic rubber fuel-binder. Present standard binders are believed to be polyester (Aeroplex) base. President is Dan C. Kimball, former Navy Secretary.

AMERICAN ROCKET: Formed in 1954, this group is active in all types of composite solids. Has specialized in gas generators and auxiliary power units but now said to be working on primary sustainer. Operated under Alfred J. Zaehringer with extensive experience in solids.

ATLANTIC RESEARCH: Since Korea, Atlantic has continued to expand its Navy-built rocket facility. Engaged in development of *Iris* and *Arcon* sounding rockets. Basis of propellants may be polymer-type (viz., epoxy, polyurethane, or vinyl). Headed by Arch C. Scurlock, strong in combustion field and V. P. Arthur W. Sloan, organic chemist.

ARMOUR RESEARCH: Has one group devoted to solid propellant research. Armour has played an active role in the development of rocket artillery—particularly the rocket gun.

EXPERIMENT, INC.: Also a research group, Experiment's work has been concentrated in problems involving the combustion of solids.

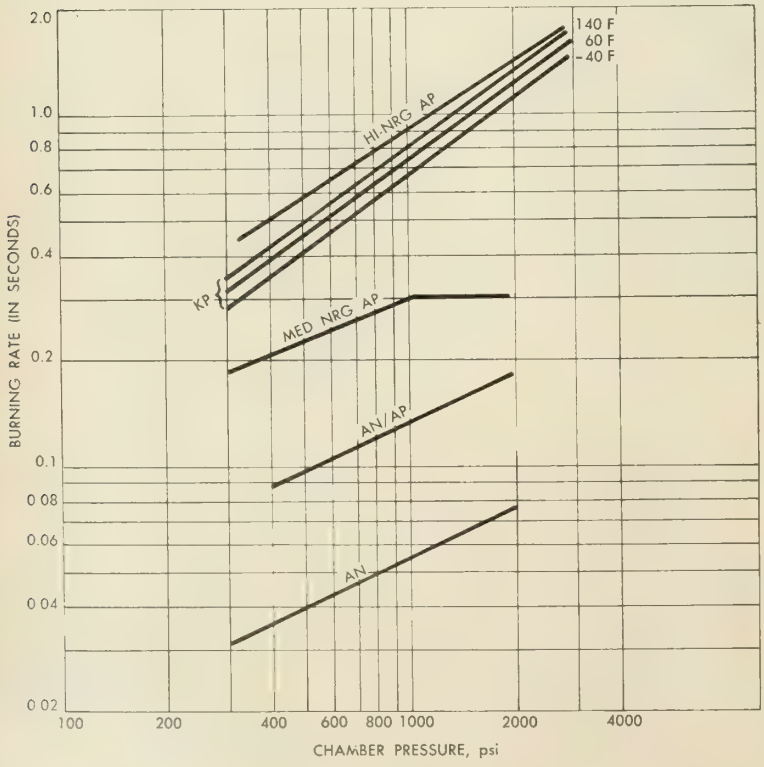
GRAND CENTRAL: Originating around Korea, GC has been divorced from its parent Grand Central Aircraft. Activities include production of *Dart, Wasp,* and *Asp* solid propellant rockets. Seems to be centered in composites. Working on third-stage Vanguard rocket using composite propellant plus conventional metal hardware. Headed by former JPL man, Charles E. Bartley, a staunch low-cost solid propellant advocate.

HERCULES POWDER CO.: Hercules Powder has operated the Allegany Ballistics Laboratory since World War II. Operations seem to be built around double-base solids. It is also now working on a third-stage *Vanguard* rocket but using a high-energy homogeneous propellant and plastic hardware. Also produces *Honest John* propellant and a RATO unit.

JET PROPULSION LABORATORY: Still a strong research and development influence in the solid field, JPL has advanced the concepts of large solid propellant rockets through its *Sergeant* design.

OLIN MATHIESON: Prior to present

*



During the past ten years solid propellants have come up fast performance-wise. A great deal of expansion, scale-up, and consolidation is now taking place. In this issue, m/r presents for the first time an exclusive and complete roundup of the US solid propellant picture. This is another in a series of m/r special services to industry.

merged firm, Olin industries under John Olin had developed considerable experience in homogeneous propellants for guns. After World War II, this experience was put to work in rocket field. Largest unclassified solid propellant activity is devoted to turbojet starters and cartridge actuated devices.

PHILLIPS PETROLEUM CO.: Entering the ammonium nitrate propellant field around Korea, Phillips now operates the large Air Force Plant No. 66 and is engaged in production of the M15 RATO and large booster rockets.

PROPELLEX CHEMICAL: Newest entry into the solid propellant field is headed by Dr. Robert A. Cooley who formerly headed double base rocket propellant operations for Olin Mathieson after World War II. Formed last year, Propellex will produce double base and composite propellants.

ROHM & HAAS: The Redstone Division is devoted to research and development of high-energy double base propellants.

REACTION MOTORS: Formerly all-liquid, RMI has recently turned to research and development of solid systems.

SOUTHWEST RESEARCH INSTITUTE: The SWRI solid propellant work has been headed toward research and development of industrial uses of solids.

STANDARD OIL CO. (IND.): Entered the ammonium nitrate solid field around Korea, this operation is headed by Wayne A. Proell. Now in production of S12 cartridge starters and other solid rockets.

THIOKOL CHEMICAL CORP.: Entered the rocket field around 1948. Rocket groups are headed by Harry Ferguson with technical head Harold W. Ritchey—cogent believer of large solid rockets. Thiokol's far-flung rocket empire now accounts for ¼-½ of company revenue. Employs composites using own polysulfide fuel-binder. Rockets: *Lacrosse, Loki, Falcon, Nike-Hercules,* RV-A-10, and *Sergeant.* Boosters: T-40, T-50, and T-55.

UNIVERSITY OF DETROIT: Formed last year for research, the Missile and Rocket Section is headed by Dr. Donald J. Kenny. Projects solid fuels for ramjets, new high-energy fuels and oxidants.

In addition, there are the offshoots of the rocket field (Table 3) whose services are required for solid propellants—viz., squibs, igniters, and rocket pyrotechnics.

Today and Tomorrow

During all of World War II, nearly $0.75 billion was spent on research, development, and production of solid propellant rockets. Since that

time a conservative estimate is that at least that much has been spent during the ten years following the war. Of this latter amount, about 75% was spent during the Korean affair. At the present time nearly $100 million per year is going into raw materials for solids, research and development, hardware, and production. At the present rate of expansion, the solid propellant industry will be worth about $250 million per year within the next five years.

It is hard to derive an employment figure for the solid rocket industry. Much smaller forces are employed than the talent being poured into the liquid business. Estimates place the employment at between 50,000 and 100,000 total if one includes all hardware, engineering, administrative, and supporting personnel. One thing is certain, however. The solid propellant industry, despite the hazards, is far safer than virtually any other industry. Figures just published by the Bureau of Labor Statistics give the overall industrial injury frequency rate as 11.1 per million man-hours. The figure for the explosives field (which takes in solids) is 2.4. Only synthetic fibers had a lower rate (2.3).

With an environment like this, the solid propellant industry cannot help growing into a new influence in this rocket age.

Solids Selling

During the past ten years solid propellants have made a great deal of progress from the specific impulse of gunpowder at about 50 seconds to near 250 seconds with the new high-energy composite solids. This progress has been made without much fanfare or ballyhoo. Indeed, so quiet has been the transition that only a few are aware of the great strides solids have made. Only now is the great operational shift to solids being realized. Probably the most cogent factor in this shift is one of the most outstanding properties of a solid propellant rocket-simplicity. Out of this extreme simplicity has come the reliability which has not yet and may never be achieved by the liquid propellant rocket. In addition, there is now obtainable a performance equal to or better than present liquid rockets. Other important factors are ease in handling and long shelf life.

All of these factors are responsible for solids selling. It is evident in our growing arsenal of missile weapons. In almost every weapons category, solids are occupying a more prominent position.

Solids first invaded the artillery field and have been strong there for about ten years—particularly for short range ballistic weapons. During World War II and the Korean operations, solid rockets were handled by the average GI under the most adverse environmental conditions. Under such battlefield environments, solid rockets gained the reliability of conventional artillery—viz., failures on the order of one in ten to a hundred thousand. The range of such artillery rockets has been constantly expanding so that *Dart, Little John, Lacrosse,* and *Honest John* have given the battlefield commander a depth of operation of about 20 miles by these simple weapons. Now, the solid *Sergeant* is about to replace the operationally complex and awkward liquid *Corporal* to give a span of about 50 miles. This, however, is not the stopping point. Already the solid *Polaris* its beginning to have its effect on the

long range rockets, *Redstone, Jupiter,* and *Thor.* Next will come a solid propellant ICBM!

Even as reliable as solids are today, the reliability picture is constantly improving. This improvement comes as a result of using well established ordnance techniques plus bringing in the latest in quality control and inspection. Solids in the RATO field have achieved an enviable reliability record: a failure of about five in one million! The reason is simple—what can go wrong in a system unburdened by plumbing, valves, controls, and containing no moving mechanical parts? For all the bugs have been ironed out in a research and development program aided by constant firings in static and dynamic tests. Obviously this results in costly development (probably no more costly than a liquid program) but the payoff comes in a superior operational product whose characteristics are well defined. For one shot operation, solids, despite their higher apparent cost, are actually cheaper. And, interestingly, the liquid people only hope to have achieved a reliability of 98% in the next ten years. Compare this to the reliability of 99.995% already attained by the average solid propellant artillery rocket or the 99.9995% attained by solid RATO.

Of course, solids have long been selling for aircraft rockets. The solid *Mighty Mouse* has done for rockets what bullets have done for guns. The larger *Falcon* is now further increasing the punch of the interceptor as is the *Sidewinder* and the *Sparrow.* The solid *Nike-Hercules* and the *Hawk* are beginning to invade the ground-to-air field. It is interesting to note that a solid propellant booster is being considered for the *Bomarc* and that an advanced solid propellant ramjet for long-range AA is in the works.

Now that unexcelled reliability and performance comparable to liquids have been achieved, three barriers (now largely mental blocks in the minds of engineers) are systematically being dis-

solved by the solid propellant industry. These so-called barriers are control, repeated operation, and cost.

The matter of control is believed to be receiving major attention. By control is meant on-off operation or throttability. Solid rockets can now be built in almost any size—even to the ICBM or larger. However, ways and means must be sought to make corrections to the pre-programmed systems of present solid propellant rockets. This is now thought to be capable of solution by design of a pre-program which will take care of most flight situations and then using smaller auxiliary rockets for corrections. Such systems are already well advanced concepts in the *Honest John*, the X-17, and the forthcoming *Vanguard*. On-off solid propellant operations for a number of cycles has already been accomplished. Efforts toward throttling solid motors have been directed toward the lines of a solid-liquid motor. However, what has been gained in throttling appears to be lost in reliability.

It is true that most solid propellant motors have been designed for one-shot operation and for most situations this has been perfectly satisfactory. However, there are many situations where recovery and repeat operation are desirable. Here solids are making an inroad through cartridge actuated devices. It is now perfectly feasible to design a large solid propellant rocket motor which can be fired, reloaded and refired for a number of times much as a gun. Such repeat operation is the key, too, for many commercial and industrial applications of solid propellant power. Within ten years, cartridge devices will have advanced to the point where large power outputs—comparable to internal combustion engines—will be possible.

In the field of costs, two factors are at play. One, as production increases, costs have been coming down. The most significant whack at solid propellant prices have been made by the cast composites—particularly ammonium nitrate types. However, the entire matter of cost is becoming less important as it is realized that solids are doing their good jobs. Despite the fact that you may buy flour, milk, eggs, and yeast cheaper than the final product, few housewives bake their own bread. Thus, a pre-packaged food industry has grown up. Solid propellants will do the same thing for the rocket industry. Here, a completely unitized rocket product, ready to use, a so-called "instant" rocket will be turned out. We are simply equating total cost and the ability to do a given job. Thus, the old engineer's forte that liquid propellants' cost is lower than

Table 5

Solid Oxidants

Material	Available Oxygen, %	Performance (1)	Cost, $/lb	Availability (2)	Exhaust
Ammonium nitrate	19.5	M	0.05-0.10	H	N

Potassium perchlorate	46.2	M	0.15	M	KCl

(1): High, over 200 sec
Medium, under 200 sec

(2): High: > 1,000,000 tons/yr
Medium: < 1,000,000 tons/yr
Low: < 1,000,000 lb/yr

Major role played by ammonium nitrate for the past ten years has been based on low cost, high availability. Performance of less than 200 sec I_{sp} is pushing it into the background. Ammonium perchlorate, with high oxygen content and I_{sp} over 200 sec, could be replaced by lithium perchlorate. U.S. production of oxidants currently exceeds the demand. Red China disclosed interest in the solid propellant field by ordering the following chemicals from Britain and Norway: ammonium nitrate, cellulose nitrate, lithium compounds, potassium chlorate, potassium dichromate, potassium nitrate, sodium nitrate, and sodium perchlorate.

One of the outstanding uses of plastics in the missile business is their application as solid fuel-binders. The number of materials available is extensive. Processing system is either thermoplastic or thermosetting although in the case of polyamide both are used. Generally, the fuel value of the plastic is good. Due to great plastic demand for many applications throughout the industry availability is high with costs not excessive. Although costs for plastics are much higher than with metals an increasing demand for the material is expected in the future. New fabrications are constantly being explored.

Table 6

Performance comparison between two well known solid grains, JPN Ballistite and SU/K Cordite. High operating pressure and burning rate of Ballistite illustrate favorable performance characteristics. Ballistite is a performance-proven propellant for air-to-air missiles.

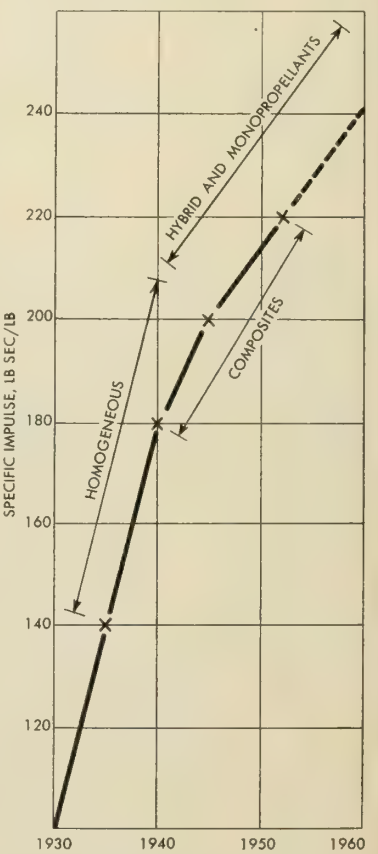
solid propellants' cost is fast falling by the wayside. And it has been demonstrated that the propellant cost of a modern missile is only a fraction—2 to 5%—of the total cost. The reasons for a lower delivery cost with solids is, again, due to simplicity. Solid rockets are generally much cheaper to build than a liquid rocket—as much as 50 or 100% cheaper in many cases. Because of the usual higher density of solids (despite somewhat lower specific impulse), solid rockets are much better in performance on a volumetric basis. In field operations, the advantages of a simple, ready-to-go solid rocket are obvious. If your rocket is difficult to service, set-up, and fire, all delivered factory price advantage disappears. And, strategically, all missiles, solid and liquid, are as vulnerable as the factory producing them.

For these reasons, solid rockets will continue to sell. They are, in effect, selling themselves.

The Propellants

Despite the wide range of ballistic performance in the various available propellants, the actual raw materials going into solids is quite limited (Table 7—Production of Solid Propellant Materials and Table 5 Solid Oxidants and Table 6 Plastics for Fuel-Binders).

Although there is a great deal of propellant activity, there is very little available information on modern solids —either composite or double base. Table 4, however, does present ballistic properties for some recent propellant formulations.



It has been a general axiom in the solid field to keep technology either in the classified or "trade secret" domain. Because of this attitude many applications have fallen by the wayside or have been passed over to the more open liquid propellant rocket industry. In addition to this potential sales loss, the very meager information has caused young engineers coming up the ladder to look to the glamour of liquids. An industry cannot continue healthy growth in such a stifling environment.

Historically, the first break away from old black powder came with the discovery of molecules which contained both oxidant and reductant (fuel) in the same compound. Such materials are nitrocellulose, nitroglycerin, and the newer diethylene glycol dinitrate. Although these and similar materials give high energy releases (performances on the order of 200 sec and to 250 sec in 5 years), stability has been a big problem. Aerojet, Hercules, and Rohm & Haas are working on new solid monopropellant molecules such as the nitropolymers, and nitrated plastics. And, it now appears fairly well certain that only the stability problem will be licked and that getting an I_{sp} of over 250 sec is a long way off.

Therefore, it seemed a matter of expediency to try mixtures of oxidant and fuel to get the desired performance and stability. These composites have achieved a great deal of stability, though perhaps at the cost of specific impulse. Only now is work being directed toward jacking up performance to 250 sec or greater. Under classification, this may already have been achieved, though outwardly composites appear to be hung up at 210-225 levels. with known compounds, getting over the 250 hump may be impossible to achieve in practical systems. Yet basic work is reported on the "weird" or "impossible" compounds which might make new oxidants or fuels. The solid people will have to seriously look at these new developments if they are to compete with the new fluorine or ozone liquid systems.

During the past ten years, ammonium nitrate has played an immense role in lower solid costs and maintaining good performance. It now looks like ammonium perchlorate which has formed the mainstay of our high energy composites may eventually lose ground to lithium perchlorate which is now being advocated. In addition, potassium perchlorate's role as an oxidant will continue on the down-grade.

Another alternative is visualized as the solid-liquid system. Only two such systems have been tried (GE with their

Tremendous rise in specific impulse for solid propellants since 1930 is seen as an outstanding engineering achievement. Composites are currently raising energy release.

hydrogen peroxide-polyethylene and the Pacific Rocket Society with LOX and polysulfide rubber). Netiher of these systems probably reached over 225 and the additional complexity was a definite disadvantage. It is even doubtful if gels, pastes, slurries and the "gunk" combinations can break through the solid impulse plateau.

The Hardware

Since the develoment of the first successful solid RATO there has been a constantly increasing buildup of hardware on the shelf in the form of RATO's, boosters, and sustainers. The accompanying table lists some of the major types now known to exist. In addition, there are available many classified units and rockets which are yet on the design boards.

In addition to better construction methods and improved reliability, the unit costs of such hardware has steadily been coming down. In a recent contract to Aerojet (an order of over twenty thousand ammonium perchloride-Aeroplex units), the familiar 1000-lb RATO dropped in cost to slightly over $160. However, lowering propellant cost on a similar unit (as evidenced from Phillips' ammonium nitrate propellant) has only dropped that figure by about $30. One can thus conclude: that unless solid propellants can be made on a continuous rather than a batch basis or unless an automated propellant plant is possible, labor costs will be the determining cost rather than low materials cost. It is also evident that a large portion of the total rocket cost will be vested in hardware rather than propellant by virtue of labor costs.

As yet the glass-reinforced plastics hardware has yet to make significant inroads into solid motors. Although some rather startling advances can be made (viz., in strength-to-weight ratios), it is also true that costs are much higher than with metals because of more hand operations. Even where machine techniques have been introduced in plastics hardware, there still appears to be too much variation for engineers to contend with. Plastics, though, are definitely here to stay, in the fabrication of solid propellant rocket hardware.

A considerable amount of scale-up has taken place since the "large" *Tiny-Tim* rocket of World War II. The scale-up barrier was first broken by development of the cast composite grains and then was closely followed by solventless cast double base grains. A conservative estimate places the impulse level of today's single grains at about the ½-1 million lb-sec mark. Indeed, it seems likely that several million lb-sec are now possible; this is borne out by the fact that Aerojet is working on a solid IRBM, the *Polaris*. It is not known if this fleet ballistic weapon will be single or multiple-staged. Now, both the double base and the composite manufacturers seem confident enough in possible scale up to say that they have not yet reached an upper size limit. Then, it seems likely that large solid propellant powerplants will first invade the IRBM class and will then follow up with a truly strategic or tactical ICBM. Application of solid propellant power to these weapons will mean that virtually any spot on earth can be used for a base.

Aside from the use of existing solid rockets as boosters or auxiliary power plants for space operations, it is certain that truly solid space rockets will have to wait until the solid IRBM and ICBM has become a reality. It also means that solids are still trailing liquids in the large-scale applications but the gap between the two is constantly drawing closer. When the gap is closed and if solids can overtake and exceed liquids remains for the solid propellant industry to accomplish by hard work.★

Table 7

Production of Solid Propellant Materials

Material	Total US Production 1956 (Short Tons)	Estimate Rocket Use 1956 (Short Tons)
Ammonium nitrate (solid only)	1,000,000	5,000
Ammonium perchlorate	3,600	3,000
Lithium nitrate	5	0.25
Lithium perchlorate	1	0.75
Nitrocellulose	10,000	1,000
Nitroglycerin	2,000	900

MISSILES & MYTHS

The bibliography of missiles, rockets and atomic power embraces the entire known history of mankind. Even the record of primordial man, when we examine what remain of his cave-drawings, indicates the use of some form of missile.

The Talmud and the Christian Bible have innumerable references to missiles and rockets; (Psalms, Proverbs, Epistles etc.) In the Bible we read: that one Ussiah (808-756 BC), ". . . made in Jerusalem, engines invented by cunning men, to be on the towers and upon the bulwarks, to shoot flaming arrows and great stones withal." We may classify these "engines" in two main groups, namely, catapults and ballista, which today are represented by howitzers and guns. (It is interesting to note that our modern word "howitzer" derives from the old Bohemian: "houfnice," a sling.)

We are told that in the 3rd Century BC a certain Dionysius invented the first recorded machine-gun, called "polybolos" or "repeater-thrower," which fired a succession of arrows from a magazine. At about the same time, an Alexandrian engineer, Ctesibius, geared pistons to a catapults arms, "working in carefully wrought cylinders, filled with compressed air."

Plutarch wrote of Archimedes in his Life of Marcellus at the siege of Syracuse, (214-212 BC): "Archimedes soon began to play his engines upon the Romans and their ships, and shot stones of such an enormous size (about 100 pounds), and with so incredible a noise and velocity that nothing could stand before them. The stones overturned and crushed whatever came in their way, and spread terrible disorder through the Roman ranks—at length the Romans were so terrified that if they saw a rope or a beam projecting over the walls they cried out that Archimedes was levelling some missile engine at them, and turned their backs and fled."

The "Atomists" of Democritus (460 BC) developed the theory that all matter is made up of exceedingly small parts, and it is significant that they called such parts "atoms," whence the word found its way into Latin and so down to us.

There exist in many museums in the world, specimens of missile type weapons of the Egyptian Neolithic Age, (circa 3200 BC). Many are in Cairo, Athens, Rome, Berlin, London and some in America. The most interesting are of flint, knapped and chipped with extraordinary care, and some with serrated edges so minute as to be hardly visible to the naked eye. They are believed to have been propelled by bows, throw-sticks, or blow-pipes, and some scientists have theorized that they were given the force of projection by tightly twisting a skein of hair or sinew, prepared in a manner unknown. The missile had a guide stick, often feathered.

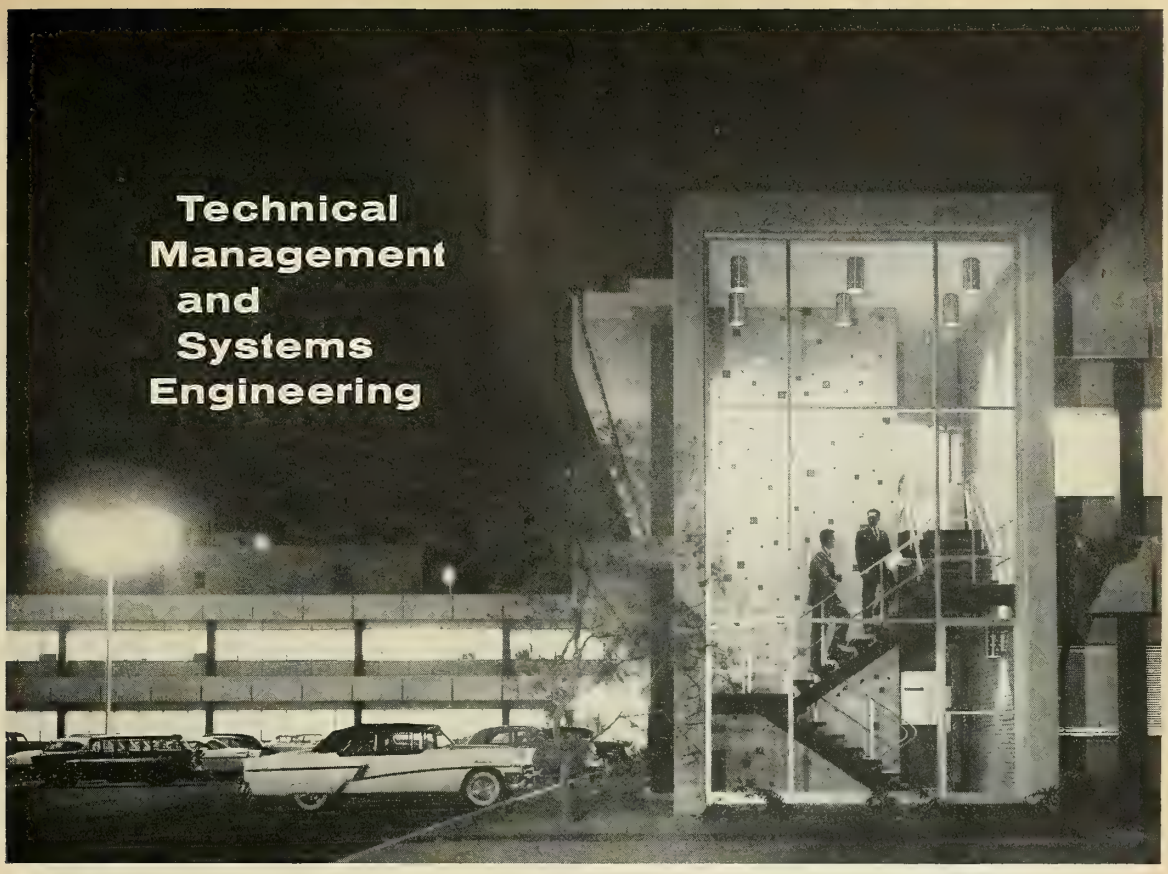
What is historically called "Greek-fire" was used as early as the 4th Century BC. It is represented in Assyrian bas-reliefs and graphically described in a record of a siege of Delium (424 BC). Here cauldrons of pitch, sulphur and burning charcoal are shown being hurled against an enemy's position. One Vegetius (350 AD) gives an interesting formula for mixtures of sulphur, naphtha, pitch, incense and tow, all packed in wooden tubes and hurled upon the decks of enemy ships where they ignited.

The Greek-fire idea transformed by modern chemistry, was seen in the two World Wars.

The rocket of the 20th Century is certainly a missile; but it had its genesis in an era before the use of gun-powder. Gun powder had been known to the Chinese long before the 13th Century and had been used both for its fusive and explosive properties. The Chinese first made use of it in a military way by setting off bombs that terrified more by noise and stench than by real destructive power. However, they discovered that rockets could be made that would provide a propellant "going by itself"; instead of advancing from an original position by a sudden force which would decrease to zero, it would increase its speed by self-contained, timed propulsion charges.

A most interesting book by an Arab, Hassan-el-Rammah Nedchureddin, (AD 1280) called "The Book of Fighting," describes a large missile to be used on water. He describes it as two pans containing a pear shaped body filled with naptha, saltpetre and two poles to serve as guides or rudders, and propelled by a series of fuses.

The closest translation from his Arabic text given by an expert is: "a flying egg." If you have ever tossed a flat object over a body of still water and watched it skid in hops, that would seem to partially describe one of the ideas of the Arabian Hassan's missile.



In 54 BC the Britons used hot clay balls as missiles to set fire to Ceasar's camp; (De Bello Gallico, Bk V); in AD 69 igneous missiles were employed in an attack on Placentia; (Tacitus, History Bk II).

During the 12th Century an engine for hurling missiles called a "trebuchet" is recorded as having a projectile force supplied by the gravitation of a heavy weight, rather than twisted cordage as in the catapult and ballista. It is reliably reported that these trebuchets threw other missiles besides stones or flaming arrows; they threw putrid corpses and sometimes live men. A dead horse in the last stages of decomposition, bundled up and shot by a trebuchet into a town in which the defenders were half dead from starvation, started a pestilence. Froissart tells us that John, Duke of Normandy, infected a town this way. Manure, offal and the dead bodies of slain soldiers were used the same way. William of Malmsebury described the Turks at Antioch throwing the heads of slaughtered townsmen into the Frankish Camp. An envoy or messenger was sometimes tied up alive and cast back into the town. (Cowper's Art of Attack.)

The idea of starting a pestilence by use of missiles for such purposes in the 12th Century, seems to have produced an echo in the 20th; until the use of poison and mustard gases, bacteriological warfare and kindred barbaric methods were internationally outlawed. We might ask ourselves if we are any more civilized than the 12th Century generals.

Certainly, our 20th Century has vastly extended the horizons of science and is continuing to fully explore, the illimitable potential science offers for humanity's benefit. Scientists of the world today have justifiable pride in their achievements. Indeed, any study of the history of missiles, rockets and atomic energy by non-scientific people will enhance the respect and appreciation our scientists merit.

Even a cursory reading of the history of missiles and rockets will convince us that there is "Nothing New Under The Sun."

In systems engineering work, it is necessary to bring together a team that includes scientists and engineers of a wide range of technical specialties. In major weapons-systems projects, such teams will include hundreds of scientists and engineers.

But the assembly of a large group of scientists and engineers, no matter how capable they may be individually, does not of itself ensure good systems-engineering performance. The caliber of the project management has a major effect upon its technical accomplishment. It is not easy to coordinate the activities of large numbers of scientists and engineers so as not to stifle their creativeness on the one hand, nor to permit the various development sub-efforts to head toward mutually incompatible objectives on the other.

Of primary importance for good systems management is the philosophy underlying the selection of the supervisory personnel. The head of a technical activity should, first of all, be a competent scientist or engineer. A common mistake — nearly always fatal in systems work — is to fill such positions by non-technical men who have been trained only in management techniques. In the highly complex activities of major systems work, what is required is *technical management*, and of the two words, the word *technical* must never be overlooked.

In the selection of scientists and engineers for technical management, it is essential that the men chosen be broad in their training and approach. Each principal department head, for example, must have a good basic understanding of the technical facts of life of the other departments. When these people get together they need to speak a common language and understand each other's fields, so that proper decisions can be made on the many interrelated problems that come up. The higher the organizational responsibility of a technical manager, the more important this factor becomes.

The Ramo-Wooldridge Corporation is engaged almost entirely in systems work. Because of this, the company has assigned to scientists and engineers more dominant roles in the management and control of the business than is customary or necessary in most industrial organizations.

Scientists and engineers who are experienced in systems engineering work, or who have specialized in certain technical fields but have a broad interest in the interactions between their own specialties and other fields, are invited to explore openings at The Ramo-Wooldridge Corporation in:

Guided Missile Research and Development
Aerodynamics and Propulsion Systems
Communications Systems
Automation and Data Processing
Digital Computers and Control Systems
Airborne Electronic and Control Systems
Basic Electronic and Aeronautical Research

THE FLIGHT HEARD 'ROUND THE WORLD

Recently three B-52 bombers flew around the world in 45 hours and 19 minutes. They were only specks in the vastness of the sky, yet they were in voice-contact every mile of the way—with SAC headquarters in Omaha, with each other, with bases along the route and with the KC-97 tankers that refueled them in the air.

Their speed-of-light contact was the AN/ARC-21 liaison communications set in each of the ships. This is a long-range, pressurized, high-altitude airborne system, capable of world-wide communications. It may be operated by the pilot, so no radio operator is needed. It is characterized by minimum training requirements, simplified maintenance, high reliability, positive channel selection —with a choice of any 20 of 44,000 frequencies.

In this as in other ways, RCA serves our Nation's armed forces. RCA scientists and engineers are constantly creating, designing and producing new and better electronic systems and equipment.

Rocket-maker Dan Kimball

Big Future, More Uses for Solid Propellants Liquids to be Limited to Specialty Roles

Former Navy Secretary Dan A. Kimball is one of the top business executives in America's incipient rocket industry. As President of Aerojet-General Corp. he has helped to pioneer many rocket firsts. Here, he outlines a glowing future for solid propellants.

Q. Mr. Kimball, will you tell us a little about Aerojet's role in solid propellants?

A. Actually we're in both the solid and liquid propellants. Aerojet was an outgrowth of the work that Cal Tech did during the war. At that time the only solid propellant we had was the old Smokey JATO unit. We built something like 200,000 of these. We made the first JATO used and the first composite propellant.

Q. Can you say anything about how much of an effort you are putting on solid propellants now compared to liquids?

A. At the present time our dollar sales in liquids engines are much ahead of the solid because of work on the ICBM, *Vanguard* engines and *Bomarc* engines. Also on the number of auxiliary powerplants. On the other hand our development work is more on solids. We've got roughly 10,000 people. We've got almost 5000 working on liquids. We've got about 3000 on solids altogether and the balance is covered with our underwater, avionics, architect and engineering divisions.

Q. What do you think the ratio of solid to liquid uses may be five years from now?

A. I think you'll have many more applications for solids. Liquids are going to lend themselves to specialized applications like ICBMs and possibly IRBMs.

Q. Why wouldn't the solid work so well for the ICBM?

A. So far we don't get the specific impulse from solids we get from liquids, but we're catching up. We're getting about 230 on solids and better than 250 on liquids. I would think in the liquid field you'd have the biggest chance for advancements in specific impulse. But when you get into the very high energy liquids you're going to have some compounds that are very difficult to handle. But I think your real growth potential in the liquid field will be for specialized applications. However, we've made some big advances in solids in the last three years.

Q. Are we at a point in solids now where we can start working with additives like borons?

A. Well, I'm no technical man but I don't think you can put zip fuel additives into solids yet.

Q. Do you think the chemical industry, generally speaking, is backing the rocket industry the way they should?

A. Well, I don't think they know what we want. In our case we've got a pretty large chemical department—as large as any group in the western United States. We've got to tell the chemical people what they should be working on although there are a number of chemical companies that are showing increasing interest. A number of people from different chemical companies come to see us at least once a week and I'd say that we visit them once a week in different fields.

Q. Does fluorine get into solid propellants?

A. Fluorine does nothing. We don't know how to put it in yet. We don't even know the uses in liquids, but we do a lot of talking about it.

Q. Do you think future solid propellant missiles can be stored for from five to ten years?

A. I would think that we'd be pretty sure if we stored them for ten years under reasonably controlled conditions. I don't think that you could let the thing cycle from 140° to —100°F. and do that four or five times a year, however.

Q. Going back to the chemical industry again—on the volume of business. In a solid propellant missile, like Honest John how much, in terms of percent of total cost do the propellant raw materials represent?

A. In the JATO unit you've got 180 pounds of which about 100 pounds is raw propellant. On top of that you have the metal parts of the propellant to process. So I'd say about 35%.

Q. Is it true that 60% of money in the missile business goes for electronics gear?

A. I don't know what the overall figures are on electronics costs. I think it depends on how complicated your missile is. I would think it would be about 1/3 powerplants, 1/3 electronics, and 1/3 fabrication and design. That's without the cost of the warhead.

Q. Would you say that a solid propellant Polaris would be less expensive than a liquid propellant Polaris?

A. In production I would think your solid propellant *Polaris* would be a little cheaper.

Q. Would you say that solid propellant missiles, on an overall basis, would be less expensive than liquids?

A. No, I don't think you could put on an overall basis. It all depends on the particular missile. The liquid engine on the *Nike* we built pretty cheaply when we build a lot of them.

Q. Is there a limiting size to solid propellant missiles where the weight of the casing would be fantastic?

A. You have a problem of handling those bigger sizes, of course. They get to weigh quite a lot. Liquids you don't have to load until your missile is on the launching site. With the solids you have to transport them. None of them yet are of a magnitude that would bother you.

Q. What about work on plastic casings?

A. We've done a lot of work on casings in several different fields of plastics and different kinds of steels.

Q. How are we coming on development of a disposal booster for the Nike?

A. I don't know that they have it yet. We haven't got one, I know. But I think more important than a disposable booster is a disposable case. It's theoretically pos-

sible to build one of those cases that will burn themselves up at the end of the run. It's not an easy job. But there are a lot of things you can do if you want to put enough money into it.

Q. Thiokol has mentioned thrust on the order of 300,000 lbs. Is this tops?

A. You've got to realize a rocket's size is a function of impulse, not thrust. We think we've fired the biggest solid propellant rocket yet, but, with the security restrictions we can't be sure.

Q. Would you care to make a size prediction for the next five to ten years?

A. Just tell us what size you want.

Q. Where is the limiting size of a single unit?

A. Well, every time we think we're near a limit then somebody builds a bigger one. This is a function of the specific impulse of the propellant and it keeps going up all the time. You see it isn't only the increase in thrust you want. You've got to have an increase in specific impulse. I think we could build a 2-or-3 or 400,000 lb. thrust solid engine, but without high impulse propellants it wouldn't be efficient. I remember 10 or 12 years ago the Army wanted a 100,000 lb. unit. We produced it in a few days and it blew up in about 1 minute.

Q. Which propellant materials show the greatest promise for the future?

A. You're going to have to find additives to raise specific impulse.

Q. Tomorrow's solid propellant engine, then, will be a truly composite unit?

A. Oh, yes. They're composite now.

Q. Can you say anything about how you're advancing on the Polaris *project?*

A. Well, we've test fired engines about the size that are to be used. You've got to work out your metal techniques and your weights and control your burning so you can stop it when you want to, however.

Q. On that subject, are you working then on powerplants that you can shut off and start again?

A. We don't know how to start them again.
